The present study seeks to compare ingredient listings between two separate surveys of United States cleaning products and their formulations conducted over a five year period as part of the American Cleaning Institute's Cleaning Product Ingredient Safety Initiative (CPISI). CPISI was conducted with the goal of providing hazard data, exposure estimates, and a screening level risk assessment for each ingredient used in member company household cleaning products. To do this, a survey was conducted to capture dish care, multi-purpose, and laundry care products and their ingredient listings. In 2012 a survey of products and their ingredients was conducted that encompassed 1,100 products and resulted in a database of over 13,000 ingredients listings. The survey captured product type and ingredient name for every listing, and captured CAS registry number, function, and concentration where these were available. The 2012 ingredient listings included over 1,200 different ingredient names, some of which were generalized naming conventions, and some of which were synonymous. Listed names were consolidated to produce the Ingredient Inventory, a list of 588 unique name-CAS registry number combinations. Each unique ingredient was assigned a chemical category and functional class. ACI is currently updating CPISI's online databases. This required repeating the survey, which was performed in 2 parts. A re-survey of products was conducted in summer 2016, with a supplemental effort in fall 2017 to capture formulations for new products entering the market in the interim. The resurvey captured data for 1,470 products, producing a database of 17,510 ingredient listings. These listings included 1,842 different ingredient names which have been consolidated to approximately 800 unique name-CAS registry number combinations. Listings and inventories were compared between the 2012 and 2016/2017 surveys and several trends were identified. Ingredient listings in 2016/2017 displayed a higher degree of specificity in naming, with more ingredients having standardized names or CAS registry numbers than in 2012. The findings of this study bear relevance to risk assessment efforts because greater specificity in ingredient listings allows more certainty when searching for and applying hazard data and allows more precision when measuring exposures for a specific ingredient across product uses.

**MP163 Study on a Prediction Model for Daily Concentration Change of Hydrogen Peroxide in Rivers**

*Y. Imaizumi, National Institute for Environmental Studies / Center for Health and Environmental Risk Research; S. Sugata, National Institute for Environmental Studies; R. Ueki, K. Takeda, H. Sakugawa, Hiroshima University; N. Suzuki, National Institute for Environmental Studies / Center for Health and Environmental Risk Research*

Hydrogen peroxide is used in many ways mainly as bleaching agent for both home and business use. It is now categorized as "Priority

Assessment Chemical Substances" in Chemical Substances Control Law in Japan, which has ecotoxicity with concern for a considerable amount of it remaining in the environment. Although Japanese government will conduct the risk assessment of hydrogen peroxide, it is hard to do because of its dynamically changeable concentration due to high reactivity with other organic and inorganic matter. In addition, hydrogen peroxide could also be produced through solar photochemical processes in both the atmosphere and surface water. In this study, we were developing a simulation model for daily concentration change of hydrogen peroxide concentration in rivers. Since hydrogen peroxide was produced through photochemical processes of dissolved organic matter (DOM) and oxygen, we were also developing a method for simulating concentrations of organic matter in river water. The model was developed based on an existing multimedia environmental fate model, G-CIEMS, and constructed geographic information system data of sewage collection areas and related effluent points of sewage treatment plants. We selected biochemical oxygen demand (BOD) and chemical oxygen demand (COD) as DOM indicators, simulated these concentrations in four river systems (Ashida River, Ohta River, Numata River, and Kurose River) in Hiroshima Prefecture, and compared these simulated concentrations with measured ones which were performed by the Japanese government. Then we simulated daily concentration changes of hydrogen peroxide in river water and compared these with measured concentrations which were collected at Rengeji Bridge, located upper stream of Kurose River, every two hours from August 24 to August 25, 2017. We also simulated influence of direct emission of hydrogen peroxide to river water from home and business use and direct depositions of hydrogen peroxide from the atmosphere which were calculated by an air pollution forecasting system, VENUS, developed in National Institute for Environmental Studies, Japan.

## Approaches and Challenges in Sediment Toxicity Testing for Environmental Risk Assessment

**MP164 Application of an undisturbed sampling technique for depth related analysis of sediment particles and pore-water in OECD 219 sediment test systems**

*M. McCoole, Bayer CropScience / Environmental Toxicology and Risk Assessment; A. Dorn, Hochschule Niederrhein / Department of Chemistry; P. Dalkmann, Bayer AG CropScience Division; D. Faber, Bayer AG CropScience / BCS D ETX Ecotoxicology; K. Hammel, Bayer AG CropScience / Environmental Safety; E. Hellpointner, Bayer AG Research & Development, CropScience / Environmental Safety; E. Bruns, Bayer AG CropScience / Ecotoxicology*

Sediment toxicity testing of plant protection products (PPP) has gained an increasing awareness within the scientific and regulatory communities. Currently, PPP concentrations in sediment and pore-water of toxicity tests according to OECD Test Guidelines 218/219 are determined as the mean over the entire sediment layer of the test system. Hence, a depth-related measurement would contribute to a more accurate assessment of the effective exposure for the test organism, *Chironomus riparius*, a predominately surface dwelling organism. Therefore, we developed an undisturbed sampling and processing technique that enables depth-related analysis of active substances in pore-water and substance bound to sediment particles. The test system was designed according to OECD Test Guideline 219. After removal of the water phase, three plastic tubes were inserted into the approximately 15 mm thick sediment layer, which was subsequently flash-frozen with liquid nitrogen. Using a specially developed cutting device, the sediment cores were cut into three slices, with an approximate thickness of 5 mm each. Each sediment slice was centrifuged to isolate the pore-water. A sequential extraction was performed to extract the sediment adsorbed residues. The pore-water and sediment extracts were analyzed by LC-MS/MS. To validate this newly devloped sampling technique, a *C. riparius* toxicity test was conducted according to the OECD 219 spiked-water sediment test method. Two model compounds, A ($logP_{ow} < 1$), and B ($logP_{ow} > 3$) were used as a mixture at nominal concentrations of 2 µg/L overlying water. To investigate the spatiotemporal behavior of the compounds, test systems were incubated and processed 3, 7, 14, 21, and 28 days after treatment. The concentrations of the applied compounds decreased in the overlying water throughout the duration of the study. Both compounds were primarily found adsorbed to the sediment phase (approximately 40 – 50%). Approximately 0.2 – 1% of the applied compounds were recovered in the pore-water at the same time. The analytical results of pore-water and sediment extracts show that the highest amounts of both compounds were in the uppermost layer of the sediment. These first results indicate that the newly developed sampling technique can provide a substantial contribution to a more realistic determination of exposure concentrations in chonic water-sediment toxicity tests, leading to an improved sediment risk assessment.

**MP165 Challenges Experienced During Development of a 96-hour Water Only Toxicity Test with the Midge, *Chironomus dilutus***

*M.J. McElroy, S.L. Clark, Pacific EcoRisk*

In 2016, a 96-hr water only exposure toxicity test method with *Chironomus dilutus* became required for some stormwater and ambient water monitoring projects in California. As a result, Pacific EcoRisk was asked to propose a method based on the EPA acute testing manual (EPA-821-R-02-012) using 7-day old organisms in order to be consistent with forthcoming revisions to the EPA and ASTM sediment testing manuals.Although "*Chironomus spp.*" is listed in Appendix B of the acute manual on a list of supplemental acute toxicity test species, only test temperature and life stage are provided for test performance. Also, a recent 96-hr *Hyalella* inter-laboratory comparison study using a similar water exposure, identified considerable variability among labs performing tests under different conditions. While our laboratory has considerable experience performing sediment testing with *C. dilutus* (e.g., 10-day to full life cycle), the sediment tests typically have at least a 14-day holding time which allows the lab to obtain egg cases and hatch organisms under controlled laboratory conditions prior to testing. Short notice of stormwater testing does not typically allow the lab to obtain egg cases, hatch them, and raise larvae to 7-days old prior to the standard EPA hold time of 36-hrs for water samples from expiring. Since implementation of this test method, we had an unacceptable frequency of invalid tests when using test organisms shipped from suppliers overnight as 6-day old larvae for testing at 7-day old larvae upon arrival. Therefore, we performed several rounds of QC testing comparing larvae reared from lab hatched egg cases, to larvae obtained from suppliers (either used immediately or after holding for 24-hrs to allow for attrition in the culture), as well as using alternate suppliers of larvae. In order to achieve a greater rate of test acceptability, two updates were eventually made to the test method. The first was increasing the hold time for this test from 36 hours to 48 hours; this provided the ability to hold larval cultures from organism suppliers for a day prior test initiation to allow for attrition of larvae that were weak due to the stress of shipping. The second update was to increase the age range of *C. dilutus* used in testing from 7-days to 7-10 days. These adjustments greatly increased the frequency of acceptable tests, especially for short-notice (e.g., stormwater) events when larvae had to be shipped from vendors.

**MP166 *Hexagenia* spp. in Toxicity Testing: Methodology Investigations and Potential Improvements**

*T. Watson-Leung, Ontario Ministry of the Environment Conservation and Parks / Aquatic Toxicology Unit; D. Kozakiewicz, Ontario Ministry of the Environment and Climate Change; A. Eade, University of Waterloo*

*Hexagenia* spp. is an ecologically important burrowing mayfly that when used sediment toxicity assessments provides an understanding of the potential toxicity to an organism with very different physiology and ecological niche than the standard test species *Chironomus dilutus* and *Hyalella azteca*. *Hexagenia* spp. have been routinely incorporated into Ontario Ministry of the Environment and Climate Change (MOECC) sediment quality assessments in the province of Ontario, Canada for almost 25 years. *Hexagenia* eggs are collected in the field from adults of the co-existing species *H. limbata* and *H. rigida* which, until recently, could not be distinguished from each other during collection. Due to DNA barcoding it is now possible to distinguish between the adults at the time of egg collection and these two species can be cultured separately. Method improvement studies by the MOECC included species-specific assessments of egg hatch out success and time to first hatch with and without storage, and species-specific growth rates and size variability in the culture. The co-efficient of variation around the potassium chloride reference toxicant tests for the MOECC mixed species *Hexagenia* was variable and sometimes quite high and it was unclear how much of this was due to the species ratio in the tests. Ninety-six-hour, water only, acute lethality tests were run with the two species and a variety of different toxicantsincluding potassium chloride, sodium chloride, ammonium chloride and copper sulfate to assess sensitivity and variability in the two species' responses. In addition, previous method improvement studies with mixed culture determined that the interpretation of the growth endpoint may be influenced by the organic content of the sediments in the 21-day MOECC sediment toxicity test method, in which the organisms are not fed. In this study the impact of species, feeding and organic carbon on the survival and growth of *Hexagenia* was assessed with a dilution series of marginally toxic sediment diluted with low TOC potters clay. The results of these method improvement investigations will be discussed.

**MP167 Toxicity of sediments under the influence of the emissary submarine of Santos using the marine amphipod *Parhyale hawaiensis***

*G. Magalhães, School of Technology, UNICAMP / LEAL Laboratory of Ecotoxicology and Environmental Microbiology; A. dos Santos, Faculdade de Ciências Farmacêuticas – USP / Departamento de Análises Clínicas e Toxicológicas; M. Artal, University of Sao Paulo – USP / Toxicology and Toxicology Analysis; F.I. Vacchi, University of Campinas / LEAL Laboratory of Ecotoxicology and Environmental Microbiology School of Technology; G.D. Umbuzeiro, School of Technology -UNICAMP / LEAL; J. Vendemiatti, School of Technology -UNICAMP*

One option for effluent discharge is the ocean because of its high depuration and dilution capacity. In Brazil, the Santos Submarine Outfall is considered one of the main emissaries of the country, reaching a volume of seven thousand liters per second. However, the practice of effluent disposal in the oceans may have negative impacts on aquatic biota. When treatment is not appropriate several contaminants can reach the water and sediments of the disposal area. This work aimed to perform acute toxicity tests with marine amphipod *Parhyale hawaiensis* with sediment samples under the influence of Santos Submarine Outfall. This organism has become a new model for toxicity tests. It has been shown to be a sensitive organism to several contaminants and is easy to be cultivated in laboratory conditions. Samples were collected at four different sites in four sampling campaigns and were evaluated as fresh sediment, dry sediment (45°C), aqueous fraction (elutriate with sediment and water), 1:4 (w/v), and organic extracts (2.5DCM:1MeOH). Liquid samples were tested using 96-wells microplates, and the sediment using 12 wells-microplates containing sediment and salt water in 1:4 (w/v). Neonates (< 7 days old) *P. hawaiensis* were used and placed individually in each well. Exposure conditions were 96h, 24+2°C, 12h/12h light and dark. At the same time that the tests were being performed, sensitivity tests were done using Zn as reference toxicant. Temperature, pH, dissolved oxygen and salinity of each sample were verified. From the 14 samples analyzed, 72% were toxic when fresh sediments were tested, and 78% when dried sediment were evaluated. All aqueous extracts were not toxic and 71% of the organic extracts tested presented toxicity. We also observed a positive correlation of toxicity with extractable organic matter. Therefore, we conclude that the sediments are being adversely affected by outfall discharge and toxicity is associated to organic contaminants. **MP168 Effects of metal contamination of streams in the Tri-State Mining District: 1Toxicity of metal mixtures to juvenile mussels in 12-week water-only test**

*J.L. Kunz, J.M. Besser, N. Wang, D. Cleveland, J.A. Steevens, USGS / Columbia Environmental Research Center*

Field studies have found that the abundance and diversity of freshwater mussels were reduced in metal-contaminated streams that drain the Tri-State Mining District (TSMD) of Missouri, Kansas, and Oklahoma. However, previous 4-week laboratory toxicity studies indicated that juvenile mussels were not among the most sensitive benthic taxa. We recently conducted a series of longer-term (12-week) toxicity tests to ensure that freshwater mussels are protected from injury from toxic metals in TSMD streams. In this study, we conducted water-only tests to evaluate the contributions of metals from stream water to toxic effects on juvenile mussels. A 2016 survey of TSMD streams found that dissolved zinc concentrations in surface water and interstitial water of mussel habitats frequently exceeded 10 ug/L at most sites downstream of mining activities. Lead and cadmium were detected in fewer samples, with these metals occurring at ratios of about 200 (Zn): 2 (Pb): 1 (Cd). We conducted 12-week tests with juvenile fatmucket *(Lampsilis siliquoidea*) to compare toxic effects of zinc exposure with the effects of a zinc-lead-cadmium mixture. Results of these studies indicated that toxic effects on juvenile mussels (reduced biomass) occurred at lower Zn concentrations in the metal-mixture test, with an EC20 of 7.2 ug/L (expressed as Zn) in the three-metal mixture, compared to 21 ug Zn/L for the Zn-only test. These results demonstrate that juvenile fatmuckets are highly sensitive to toxic effects of zinc and other metals at concentrations occurring in mussel habitats of TSMD streams. Ongoing studies in our laboratory will characterize the relative contribution of metals from TSMD sediment and overlying water to toxic effects on juvenile mussels, with the goal of establishing a reliable site-specific threshold for injury to mussel communities of the TSMD caused by metals.

## Wildlife Ecotoxicology Supporting Management Decision Making

**MP169 Assessing Trophic Magnification of Cyclic Methyl Siloxanes in a Terrestrial Food-Web of an Avian Top Predator, the Cooper's Hawk**

*K. Fremlin, Department of Biological Sciences; J.E. Elliott, Environment and Climate Change Canada / Science and Technology Branch Ecotoxicology and Wildlife Health Division; K.G. Drouillard, University of Windsor / Great Lakes Institute for Environmental Research; P.A. Martin, Environment and Climate Change Canada; F. Gobas, Simon Fraser University / Resource & Environmental Management; D. Green, Simon Fraser University / Department of Biological Sciences*

Several types of legacy persistent organic pollutants (POPs), such as PCBs and DDE, and emerging POPs like cyclic volatile methyl siloxanes (cVMS) are released from multiple sources into the ambient environment and are known to negatively impact endocrine and physiological functions within exposed wildlife. Protocols to assess bioaccumulation of these persistent chemicals within terrestrial systems are far less developed compared to aquatic systems. Presently, regulatory agencies in Canada, the USA, and the EU use only bioaccumulation information for fish to assess the bioaccumulation potential of chemicals. However, recent studies have shown that some chemicals that are not bioaccumulative in aquatic food-webs do biomagnify in terrestrial food-webs. To better understand the bioaccumulation behaviour of chemicals in terrestrial food-webs, we aim to produce a food-web model to assess the biomagnification of POPs in an apex avian predator, the Cooper's hawk. Over 100 samples were collected from various trophic levels of the food-web including hawk eggs, songbirds, invertebrates, and berries. All samples were analyzed for a number of contaminants listed as priorities for monitoring by the Chemical Management Plan of the Canadian federal government. Stable isotope analysis of $\delta^{13}C$ and $\delta^{15}N$ signatures of hawks, songbirds, invertebrates, and berries was used to estimate the trophic position of each organism. Censored regression by maximum likelihood estimation was used to assess the relationship between the natural logarithm of each contaminant lipid equivalent concentration and trophic position. Trophic magnification factors (TMFs) were determined for cVMS and legacy POPs for comparison. TMFs of PCBs, PBDEs, and OCPs ranged from 1.20 to 15.66, 3.11 to 7.32, and 0.77 to 7.79, respectively. Indicating that most legacy POPs are biomagnifying in this terrestrial food-web. TMFs of octamethylcyclotetrasiloxane (D4), decamethylcyclopentasiloxane (D5) and dodecamethylcyclohexasiloxane (D6) were estimated at 0.77 (0.12 SE), 1.17 (0.18 SE), 1.29 (0.23 SE), respectively, indicating that cVMS are either diluting or not biomagnifying in this terrestrial system. Overall, terrestrial TMF values for legacy POPs were comparable to or slightly higher than TMF values determined for several aquatic systems; however, the terrestrial TMF values for the cVMS were lower than TMF values reported in aquatic systems.

**MP170 Biomonitoting Studies of Lead and Organochlorine Pesticides in Southern European Raptor Species**

*A. García-Fernández, I. Navas, P. Gómez-Ramírez, E. Martínez-López, P. María-Mojica, University of Murcia / Health Sciences Department / Toxicology Area / Veterinary Faculty*

The most raptor species suffer the consequences of multiple pressures, such as the exposure to toxic persistent pollutants, which has been widely studied in biomonitoring programmes. These results can be used in risk assessment procedures, helping to decision makers to control adverse effects, and not only on these species, but also in the rest of the living organisms, humans included. In Spain and particularly in the southern area breeding species of migrant and non-migrant raptor are usually observed. The objectives of this study were: 1) to evaluate the exposure to lead and organochlorine pesticides in raptors from Andalusia (southern Spain), 2) to estimate potential risks related to contaminant exposures, and 3) to propose reference levels for management decision making. A total of 439 blood samples were analysed from 15 raptor species, such as Spanish Imperial eagle (*Aquila adalberti*), Bonelli's eagle (*Aquila fasciata*), Egyptian vulture (*Neophron percnopterus*), Griffon vulture (*Gyps fulvus*), Cinereous vulture (*Aegypus monachus*), Black kite (*Milvus migrans*), Eurasian sparrowhawk (*Accipiter nisus*), Eurasian buzzard (*Buteo buteo*), Bearded vulture (*Gypaetus barbatus*), Red kite (*Milvus milvus*), Northern Goshawk (*Accipiter gentilis*), etc. Raptors were chronically exposed to lead suffering sublethal effects. About 90% of non-scavenger individuals had blood lead levels below 20 µg/dL (subclinical threshold). On the contrary, about 13% of the population of obligate scavengers would require intervention. These data suggest the need for a more intensive monitoring in order to establish measures to avoid effects on scavenger populations. Griffon vultures, Bonelli's eagles and Goshawks were the most exposed to organochlorines. The most common organochlorine compounds detected were δ-HCH, lindane, endosulfan I, endosulfan sulfate and *p,p'*-DDE. These results showed that the exposure to organochlorine pesticides in Griffon vultures from Andalusia (2003-2006) followed a pattern similar to that described in vultures from Greece (2003-2004) and very different from that of the vultures from India (2005-2007), which suggests the existence of a "Mediterranean pattern of exposure to organochlorine pesticides". A decrease over time in the levels of organochlorine pesticides was observed, however *p,p'*-DDE levels in scavengers should be periodically monitored. Acknowledgements: Seneca Foundation Project MASCA'2014 (19481/PI/14). ERBFacility CA16224 COST-Action.

**MP171 Comparison of sublethal effects of eight environmental chemicals in adult and early-life stages of Japanese quail**

*E. Boulanger, McGill University / Natural Resource Sciences; D. Crump, A. Farhat, Environment and Climate Change Canada / National Wildlife Research Centre; N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre; J. Head, McGill University / Natural Resource Sciences*

Toxicity tests for avian species are generally performed on adult birds. We, and others, have proposed that the development of standardized early-life stage (ELS) toxicity tests represents an advance over current testing methodologies in terms of cost, animal use, and biological relevance. In this study we determine the effects of sublethal concentrations of 8 environmental contaminants (benzo[a]pyrene [BaP], lead (II) nitrate [Pb], seleno-L-methionine [SeMe], hexabromocyclododecane [HBCD], ethinylestradiol [EE2], fluoxetine hydrochloride [FXH], trenbolone [TB] and chlorpyrifos [CPF]) on adult and embryonic Japanese quail (JQ). For both adult and ELS studies, treatment groups included a vehicle control (Adults: corn oil, ELS: DMSO), and three concentrations of each test compound, all of which were predicted to result in < 20% mortality based on existing literature. Adult JQ (6-10 weeks of age) were exposed via oral intubation directly into the crop, whereas ELS JQ were exposed via injection into the air cell of fertilized, unincubated eggs. Liver tissues were collected from a sub-set of individuals (n=5-6 per dose group) mid-way through the experiment (Adults: day 4, ELS: day 9) for 'omics and chemical residue analysis. At the end of the experiment (Adults: day 14, ELS: day 16), the remaining individuals were examined for deformities, growth, and health metrics, and tissues were collected for histology, 'omics, and chemical residue analysis. Overall, no treatment-related mortality was observed in adult birds with the exception of Pb, which caused 100% mortality at the highest dose. Two of the 8 test chemicals, BaP and FXH, caused significant mortality in ELS JQ. The high dose of CPF was associated with a significant increase in developmental abnormalities, and a significant decrease in embryo and gallbladder mass in ELS JQ. Embryo mass was also significantly decreased by the highest dose of EE2, and tarsus length was decreased with low and high doses of HBCD. Analysis of the adult toxicity data as well as histological, 'omics, and chemical residue analysis for both life history stages is ongoing. The co-determination of a range of molecular and organismal level end points at two different life stages will help us to evaluate the feasibility of using a standardized ELS toxicity test for the evaluation of environmental chemicals in birds. This study is part of the EcoToxChip project (www.ecotoxchip.ca).

**MP172 Contaminants and cross-ecosystem linkages: food web implications for wildlife**

*J.M. Kraus, USGS / Fort Collins Science Center; K.M. Kuivila, USGS / Oregon Water Science Center; M.L. Hladik, USGS / California Water Science Center; J. Holloway, B. McGee, M. Pribil, USGS*

Contaminants can impact ecosystems by reducing the quantity and quality of aquatic insect prey available to aquatic and terrestrial consumers. Understanding these impacts allows us to predict hotspots of contaminant flux (i.e., prey production x contaminant concentration) through food webs. We summarize results from two studies examining flux of current-use pesticides and methyl-mercury from freshwaters to terrestrial food webs in adult aquatic insects to illustrate the importance of this approach to support wildlife management decisions. In the Prairie Pothole Region of North America, we found that concentrations of insecticides such as bifenthrin and imidacloprid in adult insect tissues were negatively correlated with production of adult aquatic insects during the bird breeding season. However, pesticide flux was highest from agricultural wetlands because of increased productivity of those systems due in part to nutrient inputs. In the upper Salmon River watershed in Idaho, we estimated that methyl-mercury flux from aquatic to terrestrial food webs downstream of an abandoned mercury mine increased below the point source, despite the fact that concentrations accumulating in the food web decreased, because of larger stream surface area. Adult aquatic insects emerging from these freshwaters are important prey for young waterfowl, aerial insectivorous birds and aquatic predators such as fish, and can act as vectors of contaminant transfer to multiple food webs. Non-intuitive patterns of contaminant flux result from the varying effects of habitat and contaminant on insect production. Landscape models of regional emergence and contaminant flux by adult aquatic insect prey can aid in decision making by terrestrial and aquatic wildlife managers.

**MP173 Estimating Cadmium Risks to Small Mammals: Dietary Doses and Tissue Concentrations**

*K. Fetters, M. Lindman, P.C. Fuchsman, Ramboll*

We reviewed cadmium (Cd) toxicity data to identify toxicity reference values (TRVs) applicable to small mammal survival and reproduction, with the goal of protecting local populations. The U.S. Environmental Protection Agency (USEPA) identified a mammalian TRV for Cd as 0.77 mg/kg-day, which is a NOAEL for rat growth. Growth is sometimes used as a surrogate for reproductive fitness, but this approach has limited applicability for mammals. Mammals tend to stop growing once adult size is reached, and slower initial growth can often be compensated later. Also, applicability of a rat NOAEL to small mammal TRV derivation is limited due to differences in body size, which affects exposure-effects relationships through differences in metabolism and tissue concentrations. We considered two lines of evidence for TRV development: (1) a literature review of multigenerational studies as a direct measure of Cd effects on reproductive fitness, and (2) published tissue-based TRVs. Multigenerational Cd studies are available for rats, mice, and bank voles, with NOAELs ranging from 0.0069 to 12 mg/kg-day, and LOAELs ranging from 1.5 to 2.7 mg/kg-day. The lowest LOAEL is uncertain as it reflects a behavioral effect (infanticide) without a strong dose-response relationship. Thus, a TRV range of 1.5 to 2.1 mg/kg-day is identified. For the tissue line of evidence, published TRVs have focused on renal dysfunction as the most sensitive effect, which could potentially affect survival or have a secondary effect on reproduction. This endpoint is considered conservative, because it is not a direct measure of survival or reproductive fitness. To model risks based on tissue TRVs, Cd in small mammal tissue was estimated from Cd in diet. Paired diet and tissue data for shrews were used to develop a diet-to-tissue bioaccumulation regression. This approach provides a means to address the difference in body weight and metabolism between rats (basis of TRVs) and shrews (highly-exposed species). Despite the conservative effects endpoint underlying the tissue TRV, this approach yields lower risk estimates for shrews than the dietary dose approach. We suggest that the tissue-based approach better accounts for body weight differences, and we provide a sensitivity analysis for the dose-based approach using body weight scaling as applied by USEPA for human health risk assessments.

**MP174 Influence of non-breeding season movements on patterns and trends of POPs in seabird**

*J.E. Elliott, Environment and Climate Change Canada / Science and Technology Branch / Ecotoxicology and Wildlife Health Division; A. Miller, University of British Columbia; M. Hipfner, L. Wilson, Environment and Climate Change Canada; K. Elliott, McGill University / Department of Natural Resource Sciences; S. Lee, Environment and Climate Change Canada*

There is a continuing need to monitor ecosystem contamination by xenobiotic compounds, particularly those, such as POPs, which are persistent and accumulate in food chains. Seabirds have proven to be an efficient and effective means of tracking POPs in the marine environment, and we have previously published data on long term monitoring of seabirds in the Northeast Pacific, mainly using egg samples. Seabird species can, however, be migratory with complex movement patterns outside the breeding season which can affect exposure to contaminants. Here we present data on two representative species, the rhinoceros auklet, *Cerorhinca monocerata*, a feeder mainly on small pelagic fishes, mainly over continental shelf habitat, and the ancient murrelet, *Synthliboramphus antiquus*, which uses similar habitat but feeds on more of an invertebrate diet. Both species have complex movements once they leave the breeding colonies. At a number of those colonies we collected eggs from the auklet and blood samples from the murrelet of individual birds which had been fitted with geolocator devices during the previous breeding season, and then tracked until their return to the colony the following spring. Samples were analyzed for PCBs, organochlorine pesticides, brominated flame retardants, perfluorinated compounds and stable isotopes. Data will be presented on the influence of wintering area on concentrations of those POPs compounds as discerned from telemetry and stable isotope results.

**MP175 Life history and body mass changes can influence contaminant concentrations in animals: Examples with mercury contamination in wild birds and mammals**

*S. Peterson, USGS; J.T. Ackerman, USGS / Western Ecological Research Center; C. Eagles-Smith, USGS / Forest and Rangeland Ecosystem Science Center; M. Herzog, USGS / Western Ecological Research Center; D. Costa, UC Santa Cruz / Ecology and Evolutionary Biology*

Mercury (Hg) contamination of oceans and inland waters is prevalent worldwide, posing a threat to animals in many ecosystems. Most ecotoxicological studies focus on exposure to humans and animals and the associated toxicological risk. However, the physiological changes that animals undergo throughout their annual life cycles can impact whether contaminant exposure may lead to adverse effects. Specifically, large, and sometimes rapid, changes in an animal's body mass can substantially alter contaminant concentrations. We joined the results from research in a mammalian and avian system to demonstrate how Hg concentrations can be influenced by substantial changes in mass as a result of life history events. We quantified Hg concentrations in northern elephant seals (*Mirounga angustirostris*) before and after lengthy at-sea foraging trips or fasting periods on land and showed that Hg concentrations in blood and muscle changed in response to these events. Adult female elephant seal blood Hg concentrations decreased by 30% across each of the two annual foraging trips, demonstrating a foraging-associated dilution of Hg concentrations as seals gained mass. In contrast, blood Hg concentrations increased by 103% and 24% across the two annual fasting periods (breeding and molting, respectively), demonstrating a fasting-associated concentration of Hg as seals lost mass. For Forster's terns (*Sterna forsteri*), we quantified Hg concentrations in chicks that were repeatedly sampled during the pre-fledging period when birds were rapidly gaining mass. Similarly to elephant seals, blood Hg concentrations decreased as tern chicks increased in body mass. Furthermore, we observed a strong relationship between the proportional change in chick blood Hg concentrations and the proportional change in body mass. In contrast, for seals, the proportional change in blood Hg concentrations was related to the proportional change in body mass while foraging but not fasting. Many small- and large-bodied animals undergo substantial changes in mass as a result of growth, migration, breeding, fasting, hibernation, or other life history events. Consequently, regardless of environmental exposure to Hg, an animal's toxicity risk may also be markedly influenced by changes in body mass.

**MP176 Monitoring reproductive and immunological effects in colonial waterbirds to support management decisions at contaminated Great Lakes sites**

*K. Grasman, M. Bleitz, L. Dykstra, G. Gardner, Calvin College / Department of Biology; L.L. Williams, M. Annis, US Fish and Wildlife Service; J. Moore, US Fish and Wildlife Service / Interior*

This monitoring program assessed effects of contaminants, primarily PCBs and PCDDs, on immune function and reproduction in fish-eating birds in the Saginaw Bay and River Raisin Areas of Concern (AOCs) and Grand Traverse Bay during 2010-18 under the Great Lakes Restoration Initiative and AOC programs of the US Fish and Wildlife Service and US Environmental Protection Agency. Saginaw Bay sites included two herring gull colonies (Confined Disposal Facility (CDF) and Little Charity Island), two Caspian tern colonies (CDF and Charity Reef/L. Charity Island) and one black-crowned night heron colony (CDF). Herring gulls were studied in the River Raisin AOC at the Detroit Edison Monroe Power Plant on the western shore of Lake Erie and on Bellow Island in Grand Traverse Bay. Reference sites were in the lower St. Mary's River (gulls on Pipe Island Twins and terns on Two Tree Island), on Taquamenon Island in Whitefish Bay (terns), and on Chantry Island, Lake Huron (herons). Gull embryos were assessed during late incubation using a viability detector sensitive to heartbeat and movement. Relative risk ratios for embryonic nonviability were significantly elevated two to four-fold at contaminated sites compared to the reference site (2.1 for the Saginaw Bay AOC, 2.7 for the River Raisin AOC, and 4.1 for Grand Traverse Bay). Infertility was the primary cause of nonviability at the reference site. Elevated infertility and mortality contributed to nonviability in contaminated sites. Deformities associated with PCBs and PCDDs were found in several individuals at AOCs (3 gull chicks at Monroe, 2 tern chicks on L. Charity, 2 gull embryos on the CDF, and 1 gull embryo on L. Charity). Chick productivity in terns in Saginaw Bay (mean of 0.9 chicks/nest) was significantly below that of reference sites (1.3 chicks/nest). In the River Raisin AOC, productivity of gull chicks was poor in 4 of 8 years, with complete reproductive failure during 2010. In gull chicks the mean phytohemagglutinin (PHA) skin response for T-cell mediated immunity was suppressed 52-55% at both AOCs and 46% in Grand Traverse Bay. This response was suppressed 46% in terns and 39% in herons in Saginaw Bay. Mean antibody responses in gull chicks at the River Raisin AOC and in Grand Traverse Bay were two to three-fold lower than at the reference site. Continuing immunological and reproductive impairments at these contaminated sites are consistent with the effects of persistent pollutants such as PCBs and PCDDs.

**MP177 New Approach to Developing Avian Toxicity Reference Value for Selenium**

*C.B. Meyer, B. Anthony, A.M. Thatcher, ARCADIS*

Toxicity reference values (TRVs) are used in ecological risk assessments to assess risk to wildlife species using hazard quotients. TRVs are threshold doses for risk typically developed from laboratory toxicity studies using domestic species easily raised in captivity, and as such the results of laboratory conditions and species responses may not reflect the conditions or actual risk to wildlife in the field. For metalloids such as selenium that bioaccumulate in eggs, other approaches are possible and more realistic. Because the egg is a sensitive stage for selenium toxicity and its concentration is correlated to hatching success, the egg is the ideal stage to develop avian selenium TRVs. Egg concentrations and hatchability can be measured in field nests, removing the constraint of using only laboratory studies to develop avian TRVs. In addition, a dose-response curve provides more comprehensive information for decisions than single threshold doses traditionally used. As such, a new three-step approach was applied to define a dose-based avian TRV for selenium more representative of field conditions for a former phosphate mining site in Southeast Idaho. First, dose-response curves on egg concentrations were fit to data available for 11 bird species with adequate nest datasets (pooled across studies in a meta-analysis) to predict hatching success. One (EC1) and ten (EC10) percent effect concentrations were derived from each curve. Second, to translate the egg concentration threshold to a dose-based threshold, a trophic transfer factor (TTF) of selenium from diet to egg was estimated for each species using available co-located data from field and laboratory studies. This TTF was divided into the egg concentration threshold to predict a no- and low-adverse effect level diet concentration threshold. The third step completed conversion to dose-based thresholds by multiplying the diet concentration threshold by the body-weight normalized ingestion rate for each species. Final dose-based thresholds were calculated for each species and compared to reproductive success reported for the bird community in Southeast Idaho exposed to elevated selenium on former phosphate mines. The geometric mean for the set of species provided a selenium TRV that is more consistent with reproductive success of bird populations in this area than the traditional TRV developed solely from laboratory studies. This more realistic TRV can help managers make more informed remedial decisions.

**MP178 New Approach to Developing Mammal Toxicity Reference Value for Selenium**

*B. Anthony, J. Iannuzzi, J. Zodrow, C.B. Meyer, A. Thatcher, ARCADIS*

Toxicity reference values (TRVs) are used in ecological risk assessments to assess risk to wildlife species using hazard quotients. TRVs are typically threshold doses for risk developed from laboratory toxicity studies that may or may not be representative of conditions in the field. In particular, laboratory studies determining selenium doses for mammalian toxicity thresholds do not match observations of toxicity in mammals in the field. Therefore, a TRV for selenium was developed based on field data and compared to laboratory-based TRVs. Field data evaluated included mammal studies on reproduction in areas with high selenium concentrations in the soil, sediment, vegetation and invertebrates at the Kesterson Reservoir on the Kesterson National Wildlife Refuge in southern California. Data collected from field studies conducted at Kesterson over 14 years resulted in no correlations of selenium in mammal tissue with reproductive effects. In addition, comparisons to reference areas did not reveal obvious selenium effects on the mammal community that could be differentiated from effects of differences in the habitat conditions. A 10-year biomonitoring dataset collected at Kesterson provided a data distribution for vegetation and invertebrates at Kesterson, which was used to develop a no observable adverse effect level (NOAEL) dose for the representative mammal species at the site. To corroborate this threshold level, a dose-response curve was developed using a meta-analysis approach of combining data from laboratory studies provided in USEPA's Ecological Soil Screening Level (EcoSSL) document for mortality, mortality of juveniles only, and reproductive endpoints for all mammal species in the EcoSSL database. The ten percent effect concentration ($EC_{10}$) of the dose-response curves for most species groupings were similar to the NOAEL estimated using the Kesterson field data.

## Advances in the Toxicological Assessment of PAHs

**MP179 Application of Surface Enhanced Raman Spectroscopy (SERS) for rapid PAH detection in water bodies**

*A. Kolomijea, University of Toronto; A.M. Dowgiallo, Ocean Optics; D. Sinton, University of Toronto / Department of Mechanical and Industrial Engineering; C.M. Rochman, University of Toronto*

Analytical methods for chemical detection in water bodies are often costly, time consuming and require special skills. Surface Enhanced Raman Spectroscopy (SERS) is a very attractive, non-invasive optical technique that allows rapid detection of chemicals in low concentrations and does not require large amount of sample (µL range). Authors will discuss and demonstrate the novel liquid SERS technique application we are developing to measure and analyze the 16 EPA priority PAHs. Colloidal liquid gold substrates are applied to enhance the Raman signal of the PAHs down to concentration of 1ppm. SERS spectra have been recorded applying a 785 nm laser with integration time of only 5 to 10s. This technique also allows reducing spectral shift, which can happen due to chemical interaction of analyte and substrate in conventional SERS. It is possible to identify PAHs individually or in mixtures as well as in natural water bodies. We performed real lake water PAH spiking tests to demonstrate applications of the technique. Colloidal liquid gold substrates are remarkably stable and allows us to store samples in the freezer for long times without noticeable degradation of the Raman signals.

**MP180 Assessing the risks from sediments highly contaminated with PAHs in Owen Sound Bay, Canada**

*M. Buell, Trent University / Environmental and Life Sciences; C.D. Metcalfe, Trent University / Water Quality Centre*

Sediments in the inner harbour of Owen Sound Bay in Lake Huron, Ontario, Canada are heavily contaminated with polycyclic aromatic hydrocarbons (PAHs). Proposed dredging in the harbour may pose risks to resident fish populations and to the spawning grounds of lake whitefish (*Coregonus clupiformes)*. In this study, we investigated the ecotoxicological risks posed by PAH contamination in the inner harbour of Owen Sound Bay. Through the use of SPMD passive samplers, we showed that the estimated concentrations of PAHs in the water column in the inner harbour are elevated to concentrations that exceed provincial water quality guidelines. Sediment cores were collected from several locations in the inner harbour and from a nearby reference site in Lake Huron. Total PAHs in sediments were detected at concentrations as high as 48 mg/kg dry weight, with no indication of declining concentrations to the bottom of the sediment core (i.e. 25 cm). These PAH concentrations are consistent with the levels of sediment contamination in several Areas of Concern in the lower Great Lakes. In order to make some predictions on whether dredging the sediments in the inner harbour of Owen Sound Bay pose risks to fish, sediment disturbance simulation experiments were completed with juvenile lake whitefish. We observed changes in biomarkers of exposure to PAHs, as indicated by slight induction of EROD activity, as well as significant oxidative stress, as indicated by elevated TBARS activity ($p < 0.05$). Overall, these results provide lines of evidence for assessing the ecological risks associated with PAH contamination in the inner harbour of Owen Sound Bay, and it is hoped that these data will influence future management decisions regarding dredging and/or remediation activities within the harbour.

**MP181 Benzo(a)pyrene Exposure (BaP) induces Gene Expression and Metabolic Pathway Changes in Male Tilapia**

*R. Colli-Dula, Cinvestav Unidad Merida / Recursos del Mar; X. Fang, University of Florida / Department of Pediatrics; D.A. Moraga-Amador, University of Florida / Genetics Institute; N.A. Albornoz-Abud, Cinvestav Unidad Merida / Departamento de Recursos del Mar; O. Zapata-Perez, Cinvestav-IPN Unidad Merida / Marine Resources*

Benzo (a) pyrene (BaP), the prototype of polycyclic aromatic hydrocarbons, is known to exhibits genotoxic and carcinogenic effects. Cancer promotion of BaP is associated with the activation of apoptotic signals and may induce survival signals. Recently, it has been reported that disruption in metabolic pathways has a role in carcinogenesis. One of the most studied hallmark in cancer is the Warburg effect (aerobic glycolysis). Despite a wide number of toxicological studies that describe BaP effects, the metabolic mechanisms that underlie these effects in fish are largely unknown. Of great concern is the presence of BaP in aquatic systems, especially those in close proximity to human activity leading to consumption of potentially contaminated foods. In this study we focus on the effects of repeated BaP exposure (3 mg/kg) in a short period of time (26 d) on gene alteration and changes to metabolic pathways associated with the Warburg effect in male adult tilapia. Using high-throughput RNA-Seq we identified that BaP exposure induced important changes in the gene expression of genes related with energy metabolism like hexose-6-phosphate dehydrogenase (glucose 1-dehydrogenase), acetoacetyl-CoA synthetase, malate dehydrogenase 1B and succinate dehydrogenase complex in the liver. In addition genes involved in glycolytic activities were altered such as hexokinases, phosphofructokinase and pyruvate kinase. These changes are associated with alterations in the tricarboxylic acid cycle. Pathway analysis using Gene Set Enrichment Analysis suggest that metabolic pathways including, glycolysis, biosynthesis of cholesterol, glucose and pyruvate metabolism and mevalonate pathways were altered after 26 d of repeated exposure to BaP. The gene expression and pathway alterations found indicate that BaP induced disturbances in energy metabolism, which may be involved in cancer promotion.These results constitute new insights on the mechanism of action of BaP in a non-model organism (tilapia).

**MP182 Chemical fingerprinting of polycyclic aromatic compound sources in sediments using two dimensional gas chromatography mass spectrometry**

*I.G. Idowu, W. Johnson, University of Manitoba / Chemistry; C. Sandau, P. Richards, Chemistry Matters; G. Tomy, University of Manitoba / Department of Chemistry*

Polycyclic aromatic compounds (PACs) are ubiquitous contaminants in the environment and many of them have been identified as known carcinogens. The associated toxicity of PACs makes monitoring and identification of sources of PACs in the environment important for assessing exposure to humans and wildlife. PACs sources in the environment include biogenic, petrogenic and pyrogenic and are generally a mixture of multiple sources mixed in environmental monitoring matrices. Most monitoring programs only analyze the PACs include the 16 EPA parent PAHs. When including all other unsubstituted and substituted PACs, there are thousands of potential congeners which could be measured to assess both toxicity and source allocation. In this study, 60 river sediment samples obtained from all across southern Alberta, Canada were analyzed by a gas chromatography-tandem mass spectrometer (GC-MS/MS) and two-dimensional high-resolution time of flight mass spectrometry (GCxGCHRToFMS) for comprehensive PAC chemical fingerprinting. Chemical fingerprinting helps distinguish between different sources of PAH in the environment. Data collected by these two techniques was statistically analyzed to determine the chemical patterns (fingerprints) of the predominant sources in the river systems. In addition to the conventional use of native PAHs for source identification, patterns of individual alkyl PACs identified using the GCxGCHRToFMS were also investigated to determine if additional source designation could be determined. Recent research has shown that these individual alkyl PACs can be more toxic than their unsubstituted analogues. Therefore, this information can aid in the evaluation of potential risk and used in risk assessment. Preliminary evaluation of data shows dominant petrogenic sources from coal type sources. In addition, the identification of high creosote like signatures in urban areas. On-going data analysis obtained from the GCxGCHRToFMS system will further suggest new patterns, PAH compound associations and source identification based on individual isomer of alkylated polycyclic aromatic compounds.

**MP183 Deuterated Phenanthrene Metabolites as Probes for the Metabolism of Carcinogenic PAHs in Humans: Phenotyping, Genotyping and Human Health Risk**

*K. Luo, University of Minnesota / Academic Health Center; J. Hochalter, V. Paiano, J. Wang, C.J. Sipe, S.G. Carmella, University of Minnesota Twin Cities / Masonic Cancer Center; N. Fujioka, University of Minnesota Twin Cities / Department of Medicine; S.E. Murphy, S.S. Hecht, University of Minnesota Twin Cities / Masonic Cancer Center*

Individual susceptibility plays an important role in cancer development in humans exposed to chemical carcinogens, thus identification of high-risk individuals is critical in cancer prevention and therapy. Benzo[*a*]pyrene (BaP), an important polycyclic aromatic hydrocarbon (PAH) in tobacco smoke and the environment, is considered carcinogenic to humans by the International Agency for Research on Cancer. BaP requires metabolic activation by the diol epoxide pathway to exert its carcinogenic effect, and this process differs greatly among individuals, who can't be identified based on exposure measurements only. In this study, we used deuterated phenanthrene ([$D_{10}$]Phe), a non-carcinogenic PAH with structural features and enzymology profile similar to that of BaP, as a probe substrate. The bioactivation of Phe bythe diol epoxide pathway yields the urinary metabolites phenanthrene *dihydrodiol*(Phe-Diol), phenanthrene tetraol(PheT) and phenanthrene quinone (PheQ), whereas phenanthrols (HOPhe) signify detoxification. A previous prospective epidemiological study has confirmed the statistically significant relationship between urinary levels of PheT and lung cancer risk. PheQ has been associated with the generation of reactive oxygen species (ROS) and oxidative damage, while Phe-Diol is the precursor of PheT and PheQ. We administered [$D_{10}$]Phe, with FDA approval, to smokers (N=101, 10 μg oral dose) and nonsmokers (N=87, 1 μg oral dose) and quantified the excretion of its metabolites mentioned above in urine.We have shown that this metabolism phenotyping approach is practical, accurate and precise. There are great variations among subjects in conversion of [D10]Phe to [D10]Phe-1,2-diol (31-fold/497-fold in 10 μg/1 μg dose group), [D10]PheT (51-fold/84-fold) and [D9] HOPhe (33-fold/84-fold). We hypothesize that the individuals who carry out higher ratio of bioactivation metabolites ([D10]Phe-Diol+[D10] PheT+[D8]PheQ) to detoxification metabolites ([D9]HOPhe) are at higher risk for lung cancer. Oral cell genotyping of GSTs were also determined to explore genetic causes of individual differences. The results of this innovative and unique study will vastly expand our understanding of metabolism of carcinogenic PAH in humans, thus providing new insights for human health risk assessment and lung cancer prevention.

**MP184 Effects of polycyclic aromatic hydrocarbon exposure on Gulf toadfish (*Opsanus beta*) and resiliency to co-stressors**

*M.M. Alloy, RSMAS, University of Miami / Department of Natural Resource Sciences; M. Cartolano, M. McDonald, RSMAS, University of Miami / Marine Biology and Ecology*

Polycyclic aromatic hydrocarbons (PAHs) are a ubiquitous class of contaminants associated with natural geologic petroleum deposits, and pyrogenic origins, both natural and anthropogenic (forest fires, volcanic releases, contrasted with oil spills, and combustion of petroleum and coal). Because of widespread atmospheric deposition, urban runoff, and occasionally very intensive release, such as during the Deepwater Horizon (*DWH*) oil spill, PAHs are an important class of contaminants of concern. Exposure to PAHs can be a stressor to fish; however, the response at the level of the hypothalamic-pituitary-interrenal (HPI) axis is complex. If a stress response is induced by PAH exposure, which initiates a greater production of glucocorticoids, a suite of responses follows. Two such responses examined in this work are carbohydrate metabolism and immune cell mobilization. Glucocorticoids often increase gluconeogenesis. Greater glycogen breakdown in fish has been associated with poorer body condition factors. We hypothesize that stress associated with PAH exposure will favor carbohydrate metabolism, resulting in increased gluconeogenesis, increased plasma glucose, and decreased condition factors relative to controls. The initial stress response from PAH exposure may not be deleterious to the individual, however, continuous PAH-induced stress may have a supressing effect on the immune system. Furthermore, there is a growing weight of data in the literature that chronic exposure to PAHs may interfere with the vertebrate immune response. This would reduce an organism's ability to cope with parasites, wounds, and opportunistic infections, all of which may reduce survival and fitness. We hypothesize that metabolic and immune changes induced by PAH exposure will be exacerbated by additional stressors such as simulated predator pursuit. This investigation exposed Gulf toadfish (*Opsanus beta*) to relatively low concentrations of PAHs (lower ppb range) for 7 d, followed by a depuration period of equal length. *O. beta* tissues were sampled at several timepoints during exposure (0 h, 4 h, 8 h, 24 h, and 3 d, 7 d) and parallel timepoints during depuration. Metabolic change was measured as gene expression (GCG, PYGL, GLUT1), plasma glucose, body condition factor, and hepatic-somatic index. Immune response was quantified by gene expression (CD4, TNFa, Interleukin), and immune cell counts.

**MP185 Effects on Buoyancy and Energetic Demands in Mahi Embryos Co-exposed to Crude Oil, High Temperature and UV Radiation**

*C. Pasparakis, Rosenstiel School of Marine Sciences / Marine Biology and Fisheries; L.E. Sweet, USEPA / Safer Choice Program; J.D. Stieglitz, RSMAS University of Miami / Marine Biology and Ecology; D.D. Benetti, RSMAS University of Miami / Department of Marine Ecosystems and Society; A.P. Roberts, University of North Texas / Advanced Environmental Research Institute; M. Grosell, University of Miami / Marine Biology and Ecology*

The timing and location of the 2010 *Deepwater Horizon* (DWH) incident within the Gulf of Mexico resulted in crude oil exposure of many commercially and ecologically important fish species, such as mahi-mahi (*Coryphaena hippurus*), during their sensitive early life stages (ELS). ELS mahi develop rapidly and hatched larvae are presumed to float and remain in the upper layers of the water column. In a laboratory setting, mahi embryos are positively buoyant for the duration of their development, up until the period directly preceding hatch, where they become negatively buoyant. Therefore, ELS mahi may be directly exposed to the cardiotoxic tricyclic PAHs dominating the oil slicks in surface waters for a significant portion of their developmental period. Further, these embryos are transparent and are likely also exposed to simultaneous stressors occurring in surface waters such as increased temperature and ultraviolet (UV) radiation. The maintenance of buoyancy in teleost fish is critical to survival; and aids in promoting dispersal by facilitating drift through ocean currents and positioning newly hatched larvae in the upper water columns where planktonic food is plentiful. Crude oil exposure combined with environmentally relevant stressors such as UV radiation and/or increased temperature induced early onset of negative buoyancy in mahi embryos. Further, premature negative buoyancy was coupled with increased oxygen consumption rates, faster sinking rates and significant energy depletion, likely resulting in detrimental consequences for these developing fish. Recovery of positive buoyancy was observed once the UV exposure was terminated and UV-exposed embryos did not become negatively buoyant again until right before hatch and in unison with control embryos. These results point to a behavioral response, in which embryos avoid UV exposure by sinking down the water column, implying that embryos can sense UV light and dynamically control buoyancy. This research was made possible by a grant from The Gulf of Mexico Research Initiative. Grant No: SA-1520; Name: Relationship of Effects of Cardiac Outcomes in fish for Validation of Ecological Risk (RECOVER).

**MP186 Endogenous effects in embryos of Japanese medaka exposed to oxygenated polycyclic aromatic hydrocarbons**

*M. Kawano, National Institute for Environmental Studies, Japan / Center for Health and Environmental Risk Research; S. Uno, Kagoshima University / Faculty of Fisheries; E. Kokushi, Kagoshima University / Education and Research Center for Marine Resources and Environment; J. Koyama, Kagoshima University / Faculty of Fisheries*

Oxygenated polycyclic aromatic hydrocarbons (oxyPAHs) are directly discharged into the atmosphere with exhaust gas from diesel engine automobiles and industries, and also generated through photo-oxidation and/or microbial metabolism of parent polycyclic aromatic hydrocarbons (PAHs). Because oxyPAHs have diversity of forming process, they distribute widely in environment, especially around urban area, and this is not exception in aquatic environment. Previously, fish embryos exposed to oxyPAHs were caused malformation similar with blue-sac syndrome. In this study, we examined the endogenous effects in embryos of Japanese medaka (*Oryzias latipes*) exposed to oxyPAHs such as acenaphthenquinone (ANQ), 7,12-benz(a)anthracenquinone (BAQ), 1,4-Naphthoquinone (NAQ), and 9,10-Phenanethrenequinone (PHQ). Embryos were exposed as following; 15, 150, and 1500 µg/L of ANQ; 2,20, and 200 µg/L of BAQ; 1, 10, and 100 µg/L of NAQ; and 1.5, 15, and 150 µg/L of PHQ. Solvent control group, which embryos were reared in oxyPAHs free freshwater added DMF, was also established. Then the variations with activity of ethoxyresorufin-O-deethylase (EROD), oxidative stress with generations of lipid peroxide (TBARS) and carbonyl protein, production of adenosine triphosphate (ATP), and amount of ammonia ion were individually examined in embryos with their development. EROD activity increased with increasing exposed concentration of all oxyPAHs. Additionally, oxyPAHs were actively generated ATP until 4 days post-fertilization (dpf), but significantly decreased after that. These were resulted perhaps fish embryos had continuously required the energy generation, because oxyPAHs were recognized as xenobiotics, and embryos could need the excess energy to metabolize and eliminate them. TBARS and carbonyl protein are biomarker of oxidative stress, and these were increased depending on increase of the exposure concentrations. These results suggest that oxyPAHs can cause oxidative stress in embryos. Moreover, they elevated even ammonia in embryos, embryos were expected to producing the large amount of ammonia with much ATP consumption.

**MP187 Exploring Mechanisms of Cardiotoxicity in Crude Oil Exposed Fish**

*V. McGruer, University of California, Riverside / Environmental Science; C. Pasparakis, University of Miami; A. Khursigara, The University of Texas at Austin / Marine Science Institute; S. Vliet, S. Dasgupta, D.C. Volz, University of California, Riverside / Environmental Sciences; A. Esbaugh, University of Texas Marine Science Institute / Department of Marine Science; M. Grosell, University of Miami / Marine Biology and Ecology; D. Schlenk, University of California, Riverside / Department of Environmental Sciences*

During the spring and summer of 2010 the Deepwater Horizon (DWH) oil rig released over three million barrels of crude oil into the Gulf of Mexico. As the oil dispersed it contaminated ecosystems that support numerous Gulf species including mahi-mahi (*Coryphaena hippurus*) and red drum (*Sciaenops ocellatus*). The timing of the spill coincided with the spawning of many marine species in the region and previous studies have shown that developing fish embryos are particularly sensitive to oil exposure. Numerous abnormalities due to crude oil exposure have been documented in fish early life stages, including cardiotoxicity; however, the molecular mechanisms that cause these phenotypes are not well understood. Previously, RNA sequencing was used to evaluate the transcriptomic profiles of oil exposed red drum and mahi-mahi. Subsequent mRNA analysis not only identified cardiotoxicity, but also cholesterol biosynthesis as potential targets in both species. To determine if the observed changes in gene expression have physiological relevance, mahi-mahi and red drum embryos were exposed to slick oil high-energy water-accommodated fractions (HEWAFs) until 96 hours postfertilization (hpf) and 72hpf, respectively. Total cholesterol was quantified in the resulting larvae using enzyme linked absorbance assays and indicated a trend toward reductions in both species. Immunohistochemistry was subsequently used in the zebrafish model to visualize changes in cholesterol concentrations in larval fish and was consistent with overall reductions particularly in the heart. Understanding the mechanisms involved in producing the phenotypes associated with oil exposure will contribute to assessing the ecological risk of oil spills on fish populations. This research was made possible by a grant from The Gulf of Mexico Research Initiative. Grant No: SA-1520; Name: Relationship of Effects of Cardiac Outcomes in fish for Validation of Ecological Risk (RECOVER).

**MP188 Fish embryotoxicity changes with the weathering of a conventional medium crude oil using a wave tank approach**

*V.S. Langlois, L. Lara-Jacobo, Institut National de la Recherche Scientifique / Centre Eau Terre Environnement; C. Gauthier, Institut National de la Recherche Scientifique / Centre eau; Q. Xin, H. Dettman, Natural Resources Canada / CanmetENERGY; F. Dupont, Centre Expertise en Analyse Environnementale du Québec / CEAEQ; P. Couture, Institut National de la Recherche Scientifique / Centre Eau Terre Environnement; G. Triffault-Bouchet, Centre d'Expertise en Analyse Environnementale du Québec / Écotoxicologie et Evaluation du Risque*

For several years now, CanmetENERGY's Devon Research Centre (Canada) has been performing experiments in a 1200-L wave tank examining the physical and chemical behaviours of various crude oil/water mixtures under varying temperature regimes with set wave mixing energy. A test initiated in November of 2017 used a sweet medium crude with air and water temperatures of 15 °C. Water samples were taken from the wave tank five times during a 28-day weathering experiment (at day 1, 6, 14, 21, and 28) and were used to perform toxicity exposures using fathead minnow embryos (*Pimephales promelas*). For each sampling time, newly fertilized embryos were exposed to a serial dilution of water accommodated fractions (WAFs), to non-contaminated river water (used to generate WAFs), and to aquatic facility water control. Embryos were raised until hatching, half were harvested for morphological assessment and biomarker analysis. While mortality was not significantly altered by the oil treatments, both malformation occurrence and severity showed strong concentration-responses with all the sweet medium crude treatments. Preliminary data suggest that days 14, 21, and 28 were the most toxic fractions to the fish embryos. Complementary chemistry analysis confirmed the changing concentrations of total polycyclic aromatic compounds (TPACs), volatile organic compounds, and C10-C50 with time. Noteworthy, there was an increase of oxidative compounds measured as oil weathered with time suggesting that these oxidative compounds could explain the additional toxicity observed at days 14, 21, and 28. Molecular biomarker analysis for *cyp1a* in whole larvae is ongoing. This study demonstrates the importance of modulating environmental factors, such as wave mixing energy, to best predict aquatic toxicity.

**MP189 Is cardiomyopathy a more sensitive mode of action than narcosis for polycyclic aromatic hydrocarbons (PAH) toxicity?**

*J. Kubitz, Y. Atalay, Cardno, Inc.*

There has been a growing interest in the sublethal effects of petroleum hydrocarbons, and one of the best-studied groups of compounds are the tricyclic (3-ring) polycyclic aromatic hydrocarbons (Tri-PAHs) that have been observed to elicit cardiac abnormalities in exposed fish embryos. These developmental affects have been discussed in the injury assessments of biological resources following several oil spills. There are currently uncertainties in the application of the laboratory studies in literature to quantifying adverse effects (injury) and assessing damages (lost value resulting from injuries) in the Natural Resource Damage Assessment (NRDA) process. To address part of this uncertainty, in this paper we compare the effects concentrations for acute narcosis with those for developmental deformities in Medaka (*Oryzais latipes*) for selected Tri-PAHs. We also discuss how this information can be incorporated into oil spill models to calculate deformity rates in fish following exposure to petroleum hydrocarbons.

**MP190 New methods for legacy problems: Modeling approaches to predict and evaluate chemical transformations of complex environmental mixtures**

*L. Gilbertson, V. Khanna, N. Vora, C.A. Ng, University of Pittsburgh / Civil & Environmental Engineering*

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous environmental contaminants with many natural and anthropogenic sources. Wildfires, fossil fuel extraction and use, burning of wood-derived fuels for home heating and cooking, and even food processing release a complex mixture of PAHs into air, water and soils. Once released, these substances can undergo further biological transformations mediated by microbes, fungi and higher organisms. A number of PAHs have been identified as hazardous, including the well-known carcinogen benzo[a]pyrene. Yet much less is known about which particular PAH mixtures are likely to form given a specific set of environmental and ecological conditions, nor which PAH mixtures may contain particularly toxic compounds. Experimental analysis of PAH identity and relative concentrations in complex environmental matrices is difficult and expensive, despite recent advances in non-target analyses using mass spectrometry. Since parent compound and transformation products may exhibit different degrees of solubility in water and organic solvents, for instance, different mixture components may require LC-based or GC-based methods. Here, we propose a novel framework of complementary modeling and data science approaches to prioritize PAH compounds, degradation pathways, and their products. This framework serves two important purposes: to narrow the field of relevant chemicals to be pursued by analytical means (i.e., leading to semi-targeted analysis) and to gain insight into the environmental conditions and parent structures most likely to lead to toxic compounds.

## One Health in Action – Tangible Applications for Problem Solving and Coalition Building

**MP192 Impacts of Climate Change on the Ecotoxicology of Triclosan on the Estuarine Grass Shrimp, *Palaemonids pugio***

*R. Al-Yassein, USC / ENHS; J.L. Ferry, University of South Carolina / Department of Chemistry; G. Cai, G.I. Scott, University of South Carolina / Department of Environmental Health Sciences*

Pharmaceuticals and personal care products (PPCPs) such as antimicrobial agents are one of the major contaminants of emerging concern (CECS), which are used by both humans for medical treatment and by agribusinesses to enhance the growth or health of livestock. This study evaluated the effects of increasing temperature and salinity associated with climate change conditions on the ecotoxicology of antimicrobial agent, Triclosan, (TCS)[5-chloro-2(2,4-dichlorophenoxy)-phenol], which is also known as Irgasan, which is an antibacterial agent that is widely used in soaps, toothpastes, skin creams, first-aid products, and plastics. Triclosan modes of action (resistance) or toxicity have been showed in microbes and some aquatic organisms but are not yet fully understood in terms of changing environmental conditions associated with climate change such as increasing temperature and salinity. Grass shrimp *Palaemonetes pugio*, are common inhabitants of salt marshes along the Atlantic and Gulf coasts of North America, often comprising up to 56% of pelagic macrofauna in estuarine tidal creeks and are considered a keystone species for risk assessment in coastal ecosystems. Survival of adult grass shrimp, *Palaemonetes pugio,* exposed to triclosan under standard(e.g. 20$^{o}$C, 20 Psus) and increased temperature and salinity (30$^{o}$C. 35 Psus) as a simulation of potential climate change effects, was assessed. The nominal test concentration of Triclosan ranged from 0.056-1.00 mg/L, plus a seawater control (0.1 % acetone carrier) and all tests were run in triplicate using instant ocean. Survival and behavior were the two endpoints noted in each test. Results indicated that the LC50 for Triclosan under simulated climate change conditions was more toxic, with a 96h LC50 of 0.32mg/L (CL = NC-2296.425 mg/L /L) compared to an LC50 of 0.58mg/L (CL = 0.562-0.607 mg/L) under standard conditions. These results indicate that climate change conditions must be assessed when evaluating the environmental hazards of a chemical contaminant to fully assess current and future environmental risks. As long as, consumer demand for antimicrobial products is anticipated to grow, probable prevalence of TCS increases with many concerns that the product might be harmful to human health and the environment, particularly under future climate scenarios.

**MP193 The Lancet Commission on Pollution and Health: Findings, One Health Perspectives, and SETAC Opportunities**

*N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences*

Last year the Lancet Commission on Pollution and Health was released. As one of the report co-authors, here I discuss the findings of our work and also examine these through a One Health lens (e.g., parallel research on environmental quality). The Commission addressed the full human health economic costs of air, water, and soil pollution. Stark conclusions were drawn including, for example, pollution is responsible for 9 million premature deaths per year (3-times more than AIDS, malaria, and TB combined), more than 90% of these deaths are released in low- and middle-income countries, and that it may reduce the GDP of countries by up to 2%. Furthermore, these estimates (and many more), likely underestimate the true costs of pollution owing to tremendous data gaps that remain. The Commission also pointed to several success stories that highlight that solutions and strategies can have co-benefits for the environment, health, and the economy. The Commission focused strictly on human health though similar questions can be asked about environmental quality. Here, as I systematically break down the Commission's report, I will take a One Health approach and provide examples from studies that are concerned with environmental quality and animal health (e.g., how many fish and wildlife prematurely die from exposure to pollution? What are the economic costs of this?). I will conclude with some recommendations for SETAC members based on our experiences with the Lancet Commission.

**MP194 Kewaunee County, Wisconsin: Using a "One Health" Approach to Investigate Multidimensional Aspects of Antibiotic Resistance**

*R. Beattie, E. Bakke, Marquette University / Biological Sciences; E. Munson, Marquette University / Clinical Laboratory Science; K. Hristova, Marquette University / Biological Sciences*

Surface water ecosystems are a dynamic component of the biosphere, providing food, drinking water, and diverse animal habitats. Despite the importance of surface waters, human activities have significantly altered their health, contributing multiple classes of contaminants to these waterways. In agricultural areas, manure fertilized cropland is a primary source of contamination and is a particular problem in areas of concentrated livestock farming as these farms utilize manure fertilization for convenient and economical waste management. Research on the impact of manure runoff on surface water ecosystems has focused on nutrient loads and fecal bacteria; however, emerging biological contaminants including antibiotic resistant bacteria (ARB), antibiotic resistance genes (ARGs), and pathogens have not been well studied. Here, we address this gap by using a "One Health" approach wherein we study animal, environmental, and human facets of contaminated surface water ecosystems. Using culture-based, molecular, and sequencing approaches, we have conducted a year-long monitoring study to determine the levels of ARB, ARGs, pathogens, and chemical contaminants in Kewaunee County, Wisconsin, an area dominated by concentrated livestock farming and manure crop fertilization. Results indicate pathogens and antibiotic resistant *Escherichia coli* are widely abundant in Kewaunee County surface waters, sediments, manure, and clinical isolates, including the presence extended-spectrum beta-lactamase resistance in all sample types. Additionally, environmental and manure *E. coli* isolates display significantly higher levels of resistance to beta-lactam and cephalosporin antibiotics compared to clinical isolates. These results suggest that surface water systems may serve as environmental reservoirs for antibiotic resistance to drugs of human importance. Potential pathogens from genera including *Legionella, Pseudomonas, Flavobacterium, and Burkholderia* were identified in environmental samples throughout the year-long study. Additionally, temporal patterns of ARG contamination have been identified and are primarily associated with timing of manure waste on crop fields. Together, these data provide a glimpse into the complexities of antibiotic resistance and suggest an environmental connection between livestock antibiotic resistance and human health.

## Fate of Organic Contaminants in Aquatic Invertebrates and Their Environments – Measurement, Modeling and Risk Management

**MP195 Do Bioaccumulation Metrics Depend on Exposure Concentration?**

*D. Kuo, City University of Hong Kong / Architecture and Civil Engineering*

Bioconcentration factor (BCF), biota-soil/sediment accumulation factor (BSAF), and bioaccumulation factor (BAF) are used to quantify the potential of organic compounds to accumulate in various organisms under different laboratory or field exposure scenarios. These factors or concentration ratios are currently the standard metrics for bioaccumulation and have been widely adopted in scientific, risk assessment, and regulatory contexts. Since these metrics are essentially the ratio of concentration in the biota over that in the exposure medium, a critical underlying assumption of these standard metrics is that they do not vary with exposure concentration or chemical activity. However, standard bioaccumulation measurements are often conducted at concentrations higher than at field conditions. This study attempts to examine this assumption by reviewing bioaccumulation data available in literature. With a main focus on worm related bioaccumulation data, experimental bioaccumulation factors reported across different exposure media including soil, sediment, and aqueous solution are collected and reviewed. More than 100 chemical-medium combinations were found and analyzed for dependence on exposure concentration. Results suggest that the standard bioaccumulation factors tend to decrease with increasing exposure concentration across a wide variety of chemicals. This suggests that existing bioaccumulation metrics may be inadequate, and that standard laboratory-based bioaccumulation measurements may understate the bioaccumulation risk at the field. Various causes and reasons for this dependence are examined.

**MP196 Polychlorinated Biphenyl Contamination on the Island of Unalaska**

*E. Adams, Northern Arizona University*

Polychlorinated biphenyls (PCBs) are a group of man-made, hydrophobic organochlorines that persist at highly toxic levels in the environment and biomagnify within food webs. Although banned, their continued release from pre-banned products and persistence in the environment impact human and wildlife health. PCBs are transported to the Arctic via global distillation and biomagnify to high levels in the lipid- rich food web. Thus the long-range transportation capacity of PCBs can affect food webs far from the area of release. In addition, the Arctic contains thousands of Cold War military installations, many of which are also a local source of PCB contamination. Few studies have investigated local source PCB contamination from formerly used defense (FUD) sites in the Aleutian/Bering Sea region of Alaska. PCBs have the ability to modify or suppress thyroid, reproductive and immune function. Exposure can reduce cognitive function and increase the risk of developing cancer, hypothyroidism and a host of other negative health effects. Human and animal exposure occurs via ingestion of contaminated food. PCBs were extracted from aquatic organims, focusing on important subsistence foods (i.e. salmonids, blue mussels) for the Qawalangin Tribe of Unalaska. Samples were analyzed using a modified QuEChERS method and congener-specific PCB profiles were used in target species to distinguish between point source contamination and global distillation of PCBs. Elevated levels of PCBs were found in blue mussels of two FUD sites. Levels at these two sites exceed the safe consumption limits set forth by the EPA giving supporting evidence toward the prioritization of FUD site remediation in these areas. PCB level data provided also allows the indigenous people of the area to make informed decisions about what subsistence foods are safe for consumption.

**MP197 Kinetic Sorption and Bioaccumulation of Polycyclic Aromatic Hydrocarbons in Marine Plankton Food Chain**

*F. Ko, National Museum of Marine Biology and Aquarium/ National Dong Hwa University / Institute of Marine Biology; C. Chu, National Dong Hwa University / Institute of Marine Biology*

Bioaccumulation and distribution of polycyclic aromatic hydrocarbons (PAHs) over different amounts of exposure time were investigated in the plankton food chain including phytoplankton and zooplankton. The simulated plankton food chain was using phytoplankton (*Tetraselmis chuii*), rotifers (*Brachionus* sp.), and copepods (*Apocyclops* sp.) cultured in a gas purging system with a steady supply of PAHs for 7 days in this study. The results show that PAH accumulation in plankton can be roughly divided into three sections: 0.2-1 hours, 1-24 hours, and 24-168 hours. The PAH concentrations in plankton varied greatly over the 0.2-1 and 1-24 hour time intervals, then approached study-state at 24-168 hours exposure. The low molecular weight PAHs (ACN, AC) were found at significantly higher levels in copepods than in rotifer and phytoplankton, but the high molecular weight PAHs (FA and PY) were found at significantly higher levels in phytoplankton, indicating that plankton might have selectivity towards PAHs. In principal component analysis (PCA), the plankton could be separated significantly into phytoplankton and zooplankton. Parts of the PAH accumulation found in rotifers and copepods were similar, demonstrating that PAH composition in plankton might be affected by trophic levels. All PAHs demonstrated significantly linear relationships between bioconcentration factor (BCF) and PAH hydrophobicity ($K_{ow}$) in plankton, however the different linear regression slopes of log BCF and log $K_{ow}$ between phytoplankton, rotifer and copepod, suggested that the plankton have different pathways of PAH accumulation.

**MP198 In Vivo and in Vitro Biotransformation of Chlorinated Polyfluoroalkyl Ether Sulfonate in Rainbow Trout**

*S. Yi, Univerisity of Toronto / Department of Chemistry*

Increasingly raised concerns on perfluorooctane sulfonate (PFOS) lead to its global voluntary phase-out initiatives by producers in consideration of its biological toxicities and persistence. In the meantime, 6:2 chlorinated polyfluoroalkyl ether sulfonate (6:2 Cl-PFESA, trade name F-53B) has been applied as mist suppressant to replace PFOS in metal plating industry for three decades. Recently, extensive concern has been specially focused on this class of chemical due to its widespread presence in riverine water, sewage sludge, freshwater and marine organisms, atmospheric particulate matters and human serum, with comparable or higher levels to/than PFOS. The structural similarities between 6:2 Cl-PFESA and PFOS make it reasonable to assume that 6:2 Cl-PFESA may display similar bioaccumulative potential and persistence as its predecessor. Nevertheless, the inclusion of a chlorine substitution and ether linkage in 6:2 Cl-PFESA may result in more susceptibility to biotransformation, yet no reported data has focused on their potential metabolites in biota. In this study, degradation potency of 6:2 Cl-PFESA was concomitantly investigated via in vivo and in vitro tests using juvenile rainbow trout and rat S9 as the animal model, respectively. In the in vivo tests, we examined the existence of 6:2 hydrogen-substituted polyfluoroalkyl ether sulfonate (6:2 H-PFESA) in fish blood samples as a metabolite after exposure to 6:2 Cl-PFESA in the diet for 30 days, followed by 40 days of depuration. In vitro tests further confirmed the biotransformation occurrence through detection of the same metabolite within 4 hours. This study will provide an insight on 6:2 Cl-PFESA degradation mechanisms in biota, and specify the structure-dependent manner in determining biotransformation potentials.

## Addressing Beneficial Use Impairments at Great Lakes Areas of Concern: Scientific Approaches that Lead to Restoration

**MP199 A Toolbox for Assessing Beneficial Use Impairments in Fish-Eating Birds at Areas of Concern Under the Great Lakes Restoration Initiative**

*K. Grasman, Calvin College / Biology; L.L. Williams, M. Annis, US Fish and Wildlife Service; J. Moore, US Fish and Wildlife Service / Interior*

Significant concentrations of persistent organic pollutants (POPs) including polychlorinated biphenyls (PCBs), chlorinated dioxins and furans, and organochlorine pesticides have contaminated the Great Lakes since their introduction during the 1940s-60s. Studies from the late 1960s onward have shown that fish-eating birds of the Great Lakes are excellent sentinel species for assessing and monitoring effects of contaminants including reproductive problems, deformities, and immune suppression. Two wildlife-related Beneficial Use Impairments (BUIs) at Areas of Concern (AOCs) are recognized by the Great Lakes Water Quality Agreement: 1) bird or animal deformities or reproductive problems and 2) degraded fish and wildlife populations. A current question under the Great Lakes Restoration Initiative (GLRI) and other federal and state AOC programs is whether these impairments continue. Furthermore, more recently bioaccumulative contaminants of emerging concern (CECs) have been found in Great Lakes wildlife, raising the question of whether these CECs are associated with reproductive, health and (or) population-level effects. This talk will present the tools and key results of a monitoring program studying fish-eating birds to reassess these BUIs and potential associations with legacy POPs and CECs in the Saginaw Bay and River Raisin AOCs during 2010-18 under the GLRI and AOC programs of the US Fish and Wildlife Service and US Environmental Protection Agency. Embryonic nonviability through late incubation in herring gulls in the Saginaw Bay (6.8%) and River Raisin (8.6%) AOCs was significantly higher than at the reference site (3.2%). Infertility was the primary cause of nonviability at the reference site. Elevated infertility and mortality contributed to nonviability in contaminated sites. Deformities associated with PCBs and PCDDs were found in several embryos and chicks only at AOCs. Chick productivity in Caspian terns in Saginaw Bay was significantly below that of reference sites. In the River Raisin AOC, productivity of gull chicks was very poor in 4/8 years, with complete reproductive failure during 2010. The mean phytohemagglutinin (PHA) skin response for T-cell mediated immunity was suppressed 52-55% in gull chicks at both AOCs and 46% in terns and 39% in herons in Saginaw Bay. This monitoring program has demonstrated continuing wildlife BUIs at two AOCs and provides a model for assessments that could be applied at other AOCs to support management decisions.

**MP200 Assessing the suitability of the Bad River as a reference for the St. Louis River AOC using geochemistry, biotic condition, bioaccumulation of mercury**

*J.M. Lazorchak, USEPA / Office of Research and Development; J. Hoffman, USEPA / ORD / NHEERL; M. Mills, USEPA / National Risk Management Research Laboratory; K. Fritz, USEPA / ORD / NHEERL; G. Peterson, USEPA /ORD Duluth; M. Pearson, USEPA; T. Angradi, USEPA / Office of Research and Development / Mid-Continent Ecology Division; D. Walters, USGS / Fort Collins Science Center; M. Elliott, Minnesota Pollution Control Agency; S. Janssen, USGS / Wisconsin Water Science Center / Environmental Science; J.F. Dewild, USGS / Wisconsin Mercury Research Laboratory; D.P. Krabbenhoft, USGS; E. Pilgrim, USEPA / NERL / Ecological Exposure Research Division*

The St. Louis River Area of Concern (AOC) was designated in 1987 due to Beneficial Use Impairments (BUIs), including “Restrictions on Fish and Wildlife Consumption” (BUI 1) from historical pollutants. Minnesota and Wisconsin posted fish consumption advisories for the St. Louis River, in part, because fish have elevated mercury concentrations. Mercury bioaccumulation in the food web can be from legacy sources in sediment, as well as present-day ambient sources (from both local and regional sources). In 2017 a study was conducted to achieve four goals to support the understanding of Hg sources in the AOC : 1) Compare mercury methylation and bioaccumulation by characterizing the macroinvertebrate assemblages, geochemistry, ecosystem type, and food web structure between the AOC and the reference location (Bad River); 2) Compare age- and size-specific mercury residues in select fish species between the AOC and Lower Bad River; 3) Trace food web pathways and identify mercury sources in select fish species using stable isotopes of carbon and nitrogen, and of mercury, respectively; 4) Develop a mercury-specific BUI restoration target for the AOC based on the long-term, post-remediation projected change in fish mercury residues based on the inferred differences in mercury-source bioaccumulation between the AOC and Lower Bad River. For this presentation, we will focus on Goals 1 and 3. For each location, up to five samples each were collected for mayfly (Hexagenia) larvae, odonate larvae, riparian spiders, and a composite benthic invertebrate assemblage samples using multi-plate artificial substrate samplers. For Biotic condition and mercury tissue concentrations in macroinvertebrates, a new multi-plate artificial substrate device was employed. Thirty-nine total sites were sampled with 25 sites in the AOC and 14 sites on the Lower Bad River. Sixteen samplers were deployed at each site and left to colonize for 4 weeks. When the samplers were retrieved, 12 of 14 were dissembled, scraped, sieved then picked for biomass. Two samplers were set aside for identification and metabarcoding to assess similarity in benthic communities. Macroinvertebrate assemblage, water, sediment and biota mercury, plus other water quality analyses will be presented and discussed.

**MP201 Polychlorinated Biphenyl (PCB) Inventory and Assessment in the Great Lakes Region**

*A. Shu-Yin, University of Toronto / Earth Science; L.E. Melymuk, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment; S.N. Spak, University of Iowa / School of Urban & Regional Planning; M.L. Diamond, University of Toronto / Department of Earth Sciences*

As the consummate legacy persistent organic pollutant (POP), polychlorinated biphenyls (PCBs) have long been a chemical of concern for their persistence, toxic and bioaccumulative effects. They were primarily used as dielectric fluids in electrical transformers, capacitors and other equipment. These primary sources of PCBs are on-going sources of accidental releases into the environment, which is of particular concern near bodies of water. Canada has committed to phasing out PCBs by 2025 as a signatory of the Stockholm Convention. The US does not have regulations on phasing out in-use PCBs, although national regulations stopped new production and new uses in 1974. We investigated the extent of regulatory compliance by compiling an inventory of PCBs in Ontario and US states bordering the Great Lakes. Mass of pure PCBs was estimated using the data from the Canadian Federal and Provincial (Ontario) PCB databases, and the USEPA databases. We also compared the PCB inventory for Toronto between 2006 and 2016 to assess the level of compliance with the Federal regulations. We found that the in-use and stored mass of pure PCBs in Toronto has decreased within 10 years from 420 tonnes to 0.18 tonnes. This demonstrates effective progress on regulation compliance, especially in the downtown core where PCBs were used extensively in transformers of large skyscrapers built in the 1960s and early 1970s, and in electrical infrastructure such as the public transportation system. In Ontario, 2.7 tonnes of PCBs in-use and in storage remain: they are widely distributed across the heavily populated shores of Lakes Ontario and Erie. Ontario also holds 88 tonnes of PCB waste, mostly consisting of contaminated soil/gravel. We estimated that the eight states bordering the Great Lakes (Illinois, Indiana, Michigan, Minnesota, Ohio, New York, Pennsylvania, and Wisconsin) have ca. 1900 tonnes of pure PCBs reported in-use or in storage from 1998-2011, which could be underestimated as the available registry is incomplete and out-of-date. The assessment of PCB stocks in the Great Lakes region suggests that passing binding national regulations to track and remove in-use and in storage stocks has been successful. In terms of Stockholm POPs, unfortunately this may be an exceptional case as PCBs are unique in mostly being used in contained infrastructure located in facilities that can be monitored, in contrast to legacy pesticides and flame retardants that have diffuse sources.

**MP202 A Contaminated Legacy: PCBs in Michigan’s Areas of Concern**

*E. Shaw, Michigan Technological University; N.R. Urban, Michigan Technological University / Civil and Environmental Engineering; M. Priyadarshini, Michigan Technological University*

Polychlorinated biphenyls (PCBs) are ubiquitous contaminants worldwide and are the most frequent contaminant at US and bi-national areas of concern (AOC). To address the hazardous legacy throughout the Great Lakes basin, many sites are designated as Areas of Concern (AOC) based on their impaired use (i.e. fish consumption advisories). Statewide fish consumption advisories are indicative of the breadth of the contamination problem, which is exacerbated by above average fish consumption for people living within the Great Lakes basin. Using Michigan’s fish contaminant monitoring data, this work evaluated existing evidence to answer the questions: *do existing practices enable accurate and reliable evaluation of PCB contamination at AOC sites,* and *have remediation efforts been effective?* Paired t-tests indicate significant differences in PCB concentrations between AOC and non-AOC sites for carp, largemouth bass, and walleye but not for smallmouth bass. Among the four fish species, only in carp are PCB concentrations significantly different from the other species. In some cases, toxicity of fish at both AOC and non-AOC sites exceeded the EPA’s dioxin-like compound reference dose in spite of all dioxin-like and most mono-ortho substituted PCB congeners being in < 50% of samples. The nuanced differences between AOC and non-AOC sites support recommendations for altering the current monitoring strategies to evaluate PCB contamination and efforts to remediate such sites. Time trends based on congener data were difficult to establish due to many sites having less than three years of data. Combined totals (Aroclor totals and congener totals) are used to calculate longer-term time trends but this approach ignores the discrepancies between the two methods. Furthermore, these results suggest that monitoring strategies may be inappropriate for evaluating the effects of remediation. Thus, the assumption that AOCs are significantly more contaminated than non-AOC sites may be flawed. Restructuring sampling and risk assessment methods can help us to address environmental justice issues surrounding contaminant exposure through fish consumption.

## Per- and Polyfluoroalkyl Substances: Recent Advances and Future Directions

**MP203 Short-Chain Fluorotelomer-based PFAS: Recent Advances in Toxicology, Biodegradation, Water Remediation, Assessment of Alternatives and Value-in-Use**

*S. Korzeniowski, FluoroCouncil / BeachEdge Consulting; J. Bowman, FluoroCouncil*

Per- and polyfluoralkyl substances (PFAS) is a term that describes a wide and diverse array of chemistry containing fluorine and carbon. It is noteworthy that the chemistry and properties are vastly different across the various PFAS categories and classes. The primary focus of this presentation will be on the fluorotelomer-based products with six or less fluorinated carbons (“short chain”) including fluorosurfactants, side-chain fluoropolymers and potential degradation products such as perfluorohexanoic acid (PFHxA). Fluorotelomer-based products can be in either the polymeric or non-polymeric PFAS categories. Within the non-polymeric PFAS category, fluorotelomer-based surface active agents (e.g. “fluorosurfactants”) are used in complex multi-component formulations such as cleaning products, paints, coatings and Aqueous Film Forming Foams (AFFF). The non-polymeric fluorotelomer-based products provide superior surface wetting and leveling properties and unmatched AFFF fire-fighting performance on high-hazard Class B (i.e., hydrocarbon & polar solvent liquids) fires. Within the polymeric PFAS category are the side-chain fluorotelomer-based repellent products that are used in carpets, paper products and textiles providing essential and critical properties on high-end performance and medical garments, work wear, first responder gear and in military uses. During the past two years there have been significant advances in short-chain toxicology studies, soil bio-degradation assessments, progress in the removal of short-chain acids from ground and drinking water, and various exposure assessments. This presentation will summarize a number of these critical and significant advances and present the results in the context of the overall risk in using the short-chain fluorotelomer-based products. In addition, we will discuss a decision wheel to help in the assessment of alternatives (risk vs. precaution), as well as challenges and success in the development of short-chain fluorotelomer-based products and an overview of their value-in-use including some critical end uses. Industry best practices or guidelines published by the FluoroCouncil and Fire Fighting Foam Coalition for use of these products will be highlighted during the course of this presentation.

**MP205 PFAS in NIST Standard Reference Materials**

*J. Reiner, NIST / Chemical Sciences Division*

Standard Reference Materials (SRMs) are homogeneous, well-characterized materials that are used to validate measurements and improve the quality of analytical data. The National Institute of Standards and Technology (NIST) has a wide range of SRMs that have values assigned for legacy organic pollutants. These SRMs can serve as target materials for method development and measurement for contaminants of emerging concern. Since inter-laboratory comparison studies have shown considerable disagreements when measuring per- and polyfluoroalkyl substances (PFAS), future analytical measurements will benefit from the characterization of PFAS in SRMs. Currently NIST has added measurements of over 15 PFAS to ten SRMs available for purchase. These natural matrix SRMs include human serum and plasma, fish tissue, soil, house dust, and domestic sludge. These SRMs are useful to the global analytical community and can serve as materials for quality assurance measurements and method development. This presentation will highlight the ten SRMs available and discuss how environmental and exposure science can benefit from their use.

**MP206 A rapid method for the analysis of perfluorinated alkyl substances in serum by hybrid solid-phase extraction**

*M. Honda, Wadsworth Center / New York State Department of Health; M. Robinson, K. Kannan, Wadsworth Center / New York State Department of Health / Division of Environmental Health Sciences*

A method for the analysis of thirteen perfluorinated alkyl substances (PFASs) in human serum was developed based on hybrid solid-phase extraction (hybrid-SPE) and ultra-performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS). Serum PFASs were extracted using hybrid-SPE-phospholipid cartridge after precipitating proteins and other endogenous biological interferences with 1% ammonium formate in methanol. The average intra-day accuracy (measured as percent recoveries from fortified samples) and precision of the method (measured as relative standard deviation [RSD, %] between analyses) were 88.7–117% and 1.0–13.4 %, respectively. The average inter-day precision was 2.8–6.9 %. The method was sensitive, with limits of quantification (LOQs) in the range of 0.05 to 0.09 ng $mL^{-1}$ for all 13 PFASs. The applicability of this method was tested by analyzing serum-certified standard reference material and proficiency test samples. In an hour, 100 samples can be processed by hybrid-SPE, and the instrumental run time is 5 min per sample. The developed method is rapid, inexpensive, accurate, precise, and extremely sensitive for the analysis of PFASs in human serum.

**MP207 Effect of Head Space and Reaction Time on the Quantification of Total Perfluoroalkyl Acid Precursors by Potassium Persulfate – Fluorotelomer Alcohol**

*S. Masunaga, Yokohama National University / Faculty of Environ. & Information Sci.; S. Kitaguchi, Yokohama National University / Graduate School of Environment and Information Sciences*

Per- and poly-fluoroalkyl substances (PFASs) have been receiving attention because of their persistence in the environment and global distribution. Among them, production and use of perfluorooctanesulfonic acid (PFOS) and its salts perfluorooctane sulfonyl fluoride have come to be regulated under the Stockholm Convention on POPs. The production of perfluorooctane carboxylic acid (PFOA), longer-chain homologues and their related compounds is phasing out due to the abandonment of their production by their major traditional manufacturers. However, many other perfluoroalkyl acid (PFAA) derivatives are still being produced. As they may transform into PFAAs in the environment, they are called PFAA precursors. As the precursors are numerous and diverse in their structures, it is difficult to monitor them individually. Houtz and Sedlak (ES&T, Vol. 46, p. 9342-9349, 2012) proposed a method that can determine total concentration of PFAA precursors by their oxidative conversion into perfluoroalkyl carboxylic acids (PFCAs). In this study, we evaluated this method using a volatile PFAA precursor, fluorotelomer alcohol. We selected 1H,1H,2H,2H-perfluoro-1-decanol or 8:2 fluorotelomer alcohol (8:2 FTOH) as an example of volatile PFAA precursor. This compound has 8 fluorinated carbons and a 2-carbon ethyl alcohol group. Our results indicated that head space in the reaction vessel inhibited the conversion of 8:2 FTOH to PFCAs. Complete primary degradation of 8:2 FTOH could not be accomplished even after 12-hour oxidation at 85 °C. Meanwhile, carbon chain length of produced PFCAs became shorter, namely from $C_7$

to $C_4$ through $C_6$ and small amount of $C_5$. Therefore, this method can tell only how much molarity of precursors was present in the sample and it was difficult predict the exact perfluorocarbon chain length of precursors.

**MP208 Toxicological Evaluation of 4,4,5,5,6,6,7,7,8,8,8-Undecafluoro octanoic acid (5:3 Acid)**

*R.C. Buck, S. Gannon, The Chemours Company / Fluoroproducts*

Studies were conducted to evaluate mammalian and aquatic toxicology of 4,4,5,5,6,6,7,7,8,8,8-undecafluoro octanoic acid (5:3 acid) (CAS# 914637-49-3). 5:3 acid is a metabolite of 6:2 fluorotelomer alcohol (6:2 FTOH). 6:2 FTOH is a raw material for fluorotelomer-based products. Rat oral and dermal $LD_{50}$ values were 2950 mg/kg and >5000 mg/kg, respectively. 5:3 acid produced no dermal irritation but irreversible eye irritation in rabbits, while a weak dermal sensitization response was observed in mice (LLNA), with an EC3 of 23%. A bacterial reverse mutagenicity assay and an in vivo rat micronucleus assay were negative. A 2-week rat gavage study identified red blood cells (anemia), liver (hypertrophy, focal necrosis, and increased beta-oxidation), kidney (tubular vacuolation), stomach (ulceration), and thyroid (follicular hyperplasia; of questionable relevance to humans) as target organs. Rats dosed at 600/900 mg/kg/day were euthanized *in extremis*. The NOAEL was < 30 and 30 mg/kg bw/day in males and females, respectively. In vitro metabolism was evaluated in male and female rat hepatocytes and predicted half-life in males and females of 430 and 2573 min., respectively, and identified several metabolites. Preliminary evaluations (single dose and repeat dose exposures) demonstrated that 5:3 acid exhibits biphasic pharmacokinetics. Studies demonstrated low to moderate toxicity in aquatic organisms with the following results: 72-hour EbC50 in *Pseudokirchneriella subcapitata* was 22.5 mg/ml; 90-day NOEC in rainbow trout was 9.14 mg/L; 48-hour EC50 in *Daphnia magna* was >103 mg/L; 21-day NOEC in *Daphnia magna* was 1.25 mg/L. The 90-day bioconcentration factor (BCF) measured in rainbow trout was 2.25-5.85, which supports a lack of predicted bioaccumulation in fish. 5:3 Acid, a metabolite of 6:2 fluorotelomer alcohol, is not expected to be harmful to human health or the environment at relevant concentrations.

**MP209 Binary mixtures of perfluoroalkyl acids show additive toxicity in an amphibian fibroblast cell line**

*G. Hoover, Purdue University / Forestry and Natural Resources; S. Guffey, Environmental Resources Management / Forestry and Natural Resources; C. de Perre, L.S. Lee, Purdue University / Department of Agronomy; M.S. Sepulveda, Purdue University / Department of Forestry and Natural Resources*

Perfluoroalkyl substances (PFASs) are a group of persistent organic pollutants with widespread environmental distribution in soils and surface waters. Recent research shows a potential for both bioaccumulation and toxicity of these compounds in wildlife. Due to their unique physiology and life history, amphibians are at high risk for both accumulation and toxicity following environmental exposure to these chemicals. However, understanding of the adverse effects of exposure on one of the most imperiled taxonomic groups is only beginning. Here, we examine the cytotoxic effects of these chemicals, singly and in binary mixtures, on an amphibian fibroblast cell line. We tested four common PFASs: perfluorooctane sulfonate (PFOS), perfluorooctanoic acid (PFOA), perfluorohexane sulfonate (PFHxS), and perfluorohexanoic acid (PFHxA). Of these, PFOS induced cytotoxicity at the lowest concentrations, while PFHxA was least cytotoxic. Binary mixtures allowed for the construction of isobolograms to test for additivity, super-additivity (synergism), or sub-additivity (inhibition). In all cases, regardless of functional group or carbon chain length used in the experiment, mixtures were found to be approximately additive. This data suggests that considering the sum of all PFAS present may be useful when considering effects of multi-chemical exposure.

**MP210 Toxicological Response of *Chironomus dilutus* to Six Perfluoroalkyl Compounds**

*C.J. McCarthy, Jacobs / Global Environmental Services; M. Stanaway, B. Muckey, Test America; K. O'Neal, Jacobs / Global Environmental Services; C.J. Salice, Towson University / Environmental Science & Studies Biology; D. Wright, Jacobs / Global Environmental Services; J. Rewerts, Oregon State Universtity / Department of Chemistry; J.A. Field, Oregon State University / Department of Environ Molecular Toxicology*

A multi-facetted bioassay study was conducted on six different perfluoroalkyl substances (PFAS) with the intent of obtaining data to evaluate relative or proportional toxicity between the substances. The six substances were selected from the EPA's third Unregulated Contaminant Monitoring Rule (UCMR3) list. Two of the substances, perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA), are well studied. The other four substances (Perfluorononanoic Acid [PFNA], Perfluorobutanesulfonic Acid [PFBS], Perfluorohexanesulfonic Acid [PFHxS], and Perfluoroheptanoic Acid [PFHpA]) are commonly detected in groundwater around the US, but far less is known about their toxicological potential. 10-day acute range finding tests and 20-day chronic definitive renewal bioassays were run on all six compounds using the freshwater midge, *Chironomus dilutus*. Exposure doses were established above and below environmentally relevant concentrations. Measurement endpoints included: percent larval survival; larval growth; and number of larvae, pupae, and emergent adults at test termination. Results from the 10-day acute survival tests were used to inform dosing for the 20-day chronic growth tests. Dose response curve fitting was performed for each compound. Additional statistical analysis was performed to assess the relationship between the more toxic PFOS and the other compounds. A second round of chronic testing was performed to investigate potential additive and synergistic toxicity. Organisms were exposed to mixtures containing differing proportions of the 6 compounds, based upon ratios of detected concentrations in field collected data. Results are in concert with previous work showing PFOS to be the most toxic PFAS and additive toxicity with PFHxS. Additive toxicity with other PFAS appears less clear and needs further investigation. Results of this work will be considered in conjunction with other ongoing work testing the same compounds and mixtures to look for patterns of similarity among differing classes of organisms.

**MP212 Fluoropolymers Are Unique, Low Hazard PFAS Needing Different Analytical and Regulatory Approaches**

*B. Henry, T. Kennedy, W.L. Gore & Associates, Inc.; H. Fiedler, UNEP / DTIE Chemicals Branch / MTM Research Centre School of Science and Technology*

Fluoropolymers, such as polytetrafluoroethylene (PTFE), differ from other monomeric and polymeric per- or polyfluoroalkyl substance (PFAS) classes, such as perfluoroalkyl acids, or polymeric precursors that degrade to them. Fluoropolymers do not demonstrate the same toxicity or physical/chemical/thermal properties as other PFAS. Fluoropolymers, such as PTFE do not meet the criteria of PBT (Persistent/ Bioaccumulative/ Toxic) or vPvB (very Persistent/ very Bioaccumulative) chemical substances, nor do they meet the Persistent, Mobile and Toxic (PM or PMT) substances criteria proposed by the German Environmental Agency, Umwelt Bundesamt (UBA, 2017). As high molecular weight fluoropolymers (e.g., PTFE) are benignly persistent (i.e., not mobile, bioaccumulative or toxic), all "highly fluorinated" substances do not pose equivalent health or environmental hazards and thus should not be regulated as a single class of chemicals. Chemical analytical techniques useful for differentiating one fluorinated substance from another are readily available, reliable, and reproducible and should be employed to identify and quantify those highly hazardous monomeric per- and poly-fluoroalkyl substances (PFAS) individually, rather than techniques aggregating all fluorine containing substances into one group (e.g, total organic halogen, and total organic fluorine). Therefore, high molecular weight fluoropolymers, as a uniquely benign class of polymeric PFAS, require analytical and regulatory approaches differentiating them from fluorine-containing substances that present health and environmental hazards.

## Advances in Passive Sampling Methods: Research to Application

### MP213 In situ calibration of passive sampling methods combined with multiresidue GC and LC target screen systems

*M. Allinson, The University of Melbourne / Department of Chemical Engineering; S. Sharp, The University of Melbourne / CAPIM; V.J. Pettigrove, The University of Melbourne / Sciences; M. Cassidy, C. Besley, Sydney Water Corporation; K. Kadokami, The University of Kitakyushu*

Sampling rates (Rs) for passive samplers calculated in situ should provide the best possible approximation of time weighted average water concentrations because they account for differences in water matrix and flow conditions. In this study, Chemcatchers and POCIS passive samplers were chosen to investigate trace organic chemical residues originating from either wet weather sewage overflows or urban stormwater runoff as a part of Sydney Water's "Wet Weather Overflow Monitoring" project. First phase of this project was to conduct in situ calibration of those passive samplers – Chemcatcher and POCIS combined with multi-residue GC/MS and LC/QTOF-MS database analysis methods that together can investigate about 1,300 organic chemicals including pharmaceuticals and personal care products (PPCPs), pesticides, PCBs, PAHs, flame retardants, antioxidants, sterols such as coprostanol (faecal indicator). A set of six Chemcatchers fitted with SDB-XC/SDB-RPS disks and covered with Omnipore diffusion limiting membrane, along with a set of six POCIS containing Oasis HLB sorbent were deployed at three sites in Sydney. Every week for six weeks composite water samples from autosamplers and one set of Chemcatchers/POCIS were retrieved. Each composite water sample was composed of 100mL of water collected by the autosampler every three hours for five days of each week. Duplicates, field blanks, and laboratory blanks were added for QA/QC purpose. Water samples were extracted through SDB-XC disks or Oasis HLB, and with the passive sampler disks/sorbents were eluted with dichloromethane and acetone for GC analysis, methanol for LC analysis and analysed by AIQS GC/MS or LC/QTOF-MS database methods after addition of corresponding internal standards for each GC or LC analysis. Detected chemical concentrations in water and the mass on the passive samplers were analysed to determine whether they were appropriate for calibration. Data for the first four weeks were the most ideal to obtain sampling rates (as indicated by 42 chemicals). The cost effectiveness of passive sampling for the 1300 chemicals covered by the multi-residue methods compared to autosampling is assessed.

### MP214 Passive Sampling of Surface Waters in Northern California using Chemcatcher® for Agricultural and Urban Use Pesticides

*C. Sanders, USGS; M.M. McWayne, USGS / California Water Science Center; J. Orlando, USGS.; M.L. Hladik, USGS / California Water Science Center*

Passive samplers can be deployed in the field for extended periods of time, which provides data that better represents the long-term environmental conditions of the site. This study compared pesticide detections in two different passive sampler receiving phases, Atlantic HLB (Hydrophilic-lipophilic balance) and Empore SDB-RPS (Styrene divinylbenzene reversed phase sulfonate). These were used with Chemcatcher® passive sampling devices at three locations within the Sierra Nevada and Sacramento/San Joaquin Delta. The Sierra Nevada does not have much agriculture, but has its own unique pesticide applications. Unregulated or illegal Cannabis cultivators apply unreported types and quantities, including substances banned in the United States. Pesticides are also legally used in Sierran commercial timber production and for maintenance of rights-of-way. These chemicals may be entering streams at concentrations harmful to aquatic animals and plants. A pilot study utilized the Chemcatcher® without diffusion limiting membranes (DLM) to sample surface waters downstream from Cannabis and timber production sites during the fall storm season of 2016, and with DLMs in the spring of 2017. Two different DLMs were utilized: low-density polyethylene (LDPE) was used with the Atlantic HLB, and polyethersulfone (PES) with the Empore SDB-RPS. A total of eight compounds (three herbicides, four fungicides, and an insecticide degradate) were detected. To gain insight into the differences between receiving phases as well as deploying with and without diffusion limiting membranes, additional samplers were deployed for two weeks in fall of 2017 in an area with known pesticide detections (Ulatis Creek, within the Delta). A total of 27 pesticides were detected from Ulatis Creek, 6 of which were detected in the HLB, and 24 in the SDB-RPS. The membranes from the passive samplers deployed at Ulatis Creek were also analyzed, and a total of 20 pesticides were detected, 4 of which were detected in the LDPE and 20 in the PES.

### MP215 Evaluation of Equilibrium Passive Sampling Polymers for Monitoring Munition Constituents in Aquatic Systems

*M. Rakowska, National Research Council of the National Academies/ USEPA / AED / Civil and Environmental Engineering; L.A. Fernandez, Northeastern University; R.M. Burgess, USEPA / Atlantic Ecology Division*

A wide array of military munition constituents are present in water bodies surrounding historically deposited unexploded ordnance.A common approach for monitoring explosive constituents involves the collection of large quantities of discrete water samples combined with solid phase extraction to insure sufficient sensitivity and detection. More recently, polar organic chemical integrative samplers (POCIS) have been tested for in situ assessment of munition compounds at underwater sites. However, POCIS requires extensive calibration prior to exposure in the field (i.e., determination of sampling rates). Simple and sensitive monitoring efforts are necessary to better understand the bioavailability and potential long-term bioaccumulation and toxicity of military munition constituents in different aquatic environments. In this study, the nonpolar polymers polydimethylsiloxane (PDMS), low density polyethylene (LDPE) and polyoxymethylene (POM), typically used to measure freely dissolved ($C_{\text{free}}$) concentrations of legacy contaminants in surface water and sediment porewaters, are evaluated as equilibrium passive samplers for munition constituents. The use of POCIS sorbents including Oasis HLB, Ambersorb and Isolute Env$^{+}$ in an equilibrium sampling approach is also being investigated and compared to the performance of nonpolar samplers. All polymer materials were successfully loaded in methanol followed by solvent evaporation with the munition constituents nitroguanidine, hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX), 2-amino-4,6-dinitrotoluene and tetryl serving as performance reference compounds (PRCs). Loaded polymers were exposed in batch water systems spiked with the munition constituents 4-amino-2,6-dinitrotoluene, pentaerythritol tetranitrate (PETN) and 1,3,5,7-tetranitro-1,3,5,7-tetraazacyclooctane (HMX). The release and uptake of explosive compounds was monitored in polymer and water phases over time. Preliminary results suggest that the stronger affinity of PETN to PDMS may be explained by its higher octanol-water partition coefficient (log $K_{OW}$= 3.7) as compared to other munition constituents in the water phase, and thus favored hydrophobic interactions with the polymer. The presentation provides information both on the uptake and release of explosive compounds to a variety of polymeric materials and discusses their potential for application in equilibrium passive sampling.

### MP216 Demonstration of Passive Sampling Devices for Monitoring of Munitions Constituents in Underwater Environments

*G.H. Rosen, SPAWAR Systems Center / Energy and Environmental Sustainability; G.R. Lotufo, U. S. Army ERDC / Environmental Laboratory; R.D. George, SPAWAR Systems Center Pacific / Environmental Sciences; J.B. Belden, Oklahoma State University / Integrative Biology*

As a result of military activities, unexploded ordnance (UXO) and discarded military munitions (DMM) are present in underwater environments, which has resulted in the release of munitions constituents (MC) including the high explosives, 2,4,6-trinitrotoluene (TNT) and hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX), along with their primary degradation products, to the water column and adjacent sediments. This research focused on the optimization and field validation of a commercially available in situ passive sampling device, the Polar Organic Chemical Integrative Sampler (POCIS), for detection and quantification of MC in underwater environments. POCIS provide integrative, continuous sampling in situ, and ultra-low detection limits and potentially more meaningful time-weighted averaged (TWA) water concentrations, compared with more traditional sampling (e.g. grab) methods. Sampling rates for multiple MC were determined, and accounted for parameters (e.g. flow velocity, biofouling) that are known to influence POCIS uptake rate. These laboratory based efforts were followed by two unique field demonstration efforts. The first involved an uncontaminated estuarine site where a known quantity of the explosive fill material Composition B (39.5% TNT, 49.5% RDX, 1% wax) was placed. TWA concentrations for TNT and RDX ranged from 9 to 103 ng/L, with the highest concentrations nearest the Composition B source, but all samplers positioned greater than 2 m from the source resulted in non-detects. The controlled study was followed by placement of POCIS within the Live Impact Area at the former Vieques Naval Training Range at Bahia Salina del Sur (Vieques, Puerto Rico), a bay with documented high incidence of munitions items including UXO. The Vieques study design involved POCIS placement within ~6" of 15 potentially leaking UXO, and an unbiased (i.e. a grid design over a ~200 acre area) placement, also 15 locations, in the bay. When detected, TWA concentrations for TNT and RDX were observed at ultra-trace concentrations (range = 4 to 13 ng/L), except 6" from an apparent leaking munition where the TNT TWA concentration was 5.3 µg/L. All detects were at least two orders of magnitude lower than ecological risk thresholds derived from recently updated species sensitivity distributions for these constituents.

**MP217 Monitoring Neonicotinoid Insecticides with Pocis Passive Samplers in Watersheds of the Great Lakes Basin in Ontario, Canada**

*C.D. Metcalfe, Trent University / Water Quality Centre; P.A. Helm, Ontario Ministry of the Environment & Climate Change / Environmental Monitoring and Reporting Branch; T. Sultana, Trent University / Environmental and Resource Studies*

We evaluated the distribution and concentrations of a range of neonicotinoid (NNI) and structurally related insecticides in watersheds that drain into the lower Great Lakes in Ontario, Canada. Polar Organic Chemical Integrative Samplers (POCIS) were deployed in 18 watersheds during late May to late June of 2016. Grab samples were also collected in 7 of these watersheds. Sampling rates determine in the laboratory (i.e. $R_{s\text{-}cal}$) were adjusted according to the loss of Performance Reference Compounds in POCIS deployed in the field (i.e. $R_{s\text{-}field}$) to compensate for the effects of environmental conditions on sampling rates. There was generally good agreement between the time-weighted average concentrations of NNIs estimated from the POCIS and the concentrations detected in grab samples. The monitoring data indicated that the NNIs, thiamethoxam, clothianidin and imidacloprid were present in several watersheds at concentrations that exceeded the Canadian Water Quality Guideline for imidacloprid of 0.23 µg/L. The new generation insecticides, flonicamid and flupyradifurone were also detected in some watersheds, which is the first report of these insecticides occurring in aquatic ecosystems. These data will be discussed in terms of the potential for using POCIS passive samplers for regulatory applications.

**MP218 Calibration of organic-diffusive gradients in thin films (o-DGT) passive samplers for per- and polyfluoroalkyl substances in water**

*P. Wang, Jinan University / School of Environment; J.K. Challis, University of Manitoba / Chemistry; K. Luong, University of Winnipeg / Richardson College for the Environment; C.S. Wong, University of Winnipeg / Department of Chemistry*

Per- and polyfluoroalkyl substances (PFASs) are organic pollutants known to be persistent, toxic and bioaccumulative in the environment, thereby posing a great concern towards human and ecosystem health. In this study, a passive sampling technique that uses organic-diffusive gradients in thin films (o-DGT) was developed for the measurement of six PFASs, including perfluorobutanesulfonic acid (PFBS), perfluorooctanesulfonic acid (PFOS), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), perfluorodecanoic acid (PFDA), and perfluoroundecanoic acid (PFUA) in water. The determination of diffusion coefficients (D) of PFASs at 5 $^{o}$C (1.13–2.46 $\times 10^{-6}$ $cm^2/s$) and 23 $^{o}$C (2.34–3.88 $\times 10^{-6}$ $cm^2/s$) showed that the difference in D values, ranging from 29% to 53%, was a result of slower diffusion at 5 $^{o}$C. The calibration experiment compared measured and predicted sampling rates at 23 $^{o}$C and showed that the average relative error of PFBS, PFOS, PFOA, PFNA, PFDA and PFUA were 3%, 36%, 37%, 37%, 25% and 26%, respectively, which were within 40% of each other, which is reasonable for passive samplers. This observation demonstrated that we can accurately predict in-situ sampling rates using measured D-values, thereby eliminating the need for full-scale calibration. The total uptake capacities of Sepra™ ZT weak-anionic exchange (WAX) binding gels for six PFASs suggested field deployments of 21 days will ensure linear uptake, which are suitable for long-term environmental monitoring, but because of the difference of water pollution at the sampling rates, we suggest that a reduced deployment time e.g.,10 days will also meet the measurement requirements. We conducted field demonstrations of this configuration of the o-DGT in surface waters impacted by PFAS, downstream of two wastewater treatment plants (WWTPs) or industrial areas around Guangzhou, China. The concentration of PFASs ranged from16.9–125 ng/L. This study has demonstrated that o-DGT provides a cost-effective monitoring tool to determine accurate concentrations of PFASs in aquatic systems.

**MP219 Organic-Diffusive Gradients in Thin-Films Passive Samplers: Current State of Research, Applications, and Future Directions**

*J.K. Challis, University of Manitoba / Chemistry; C.S. Wong, University of Winnipeg / Department of Chemistry*

Over the past five years, the organic-diffusive gradients in thin-films (o-DGT) passive sampler has emerged as a promising tool for accurate measurement of polar organic contaminants in aquatic systems. The success of o-DGT stems from the inclusion of an uptake-limiting diffusive hydrogel, greatly reducing the effects of the water boundary layer, and thus in situ flow rate conditions. As a result, o-DGT sampling rates can be estimated based on diffusion through the agarose diffusive gel, facilitating simple and accurate sampler calibration and a means by which to account for temperature effects in situ. A number of studies have successfully tested o-DGT for pharmaceuticals, personal care products, and pesticides, and demonstrated its utility and advantages over current polar passive samplers (e.g., POCIS). However, the o-DGT technique is still new and requires further research to address a number of fundamental questions regarding approaches to sampler calibration, optimized configurations, and mechanisms controlling/impacting uptake. This poster will summarize the current state of this research in the published literature, highlight successful applications, discuss current challenges and knowledge gaps, and make recommendations as to where future research efforts should focus in order to best advance this technique.

**MP220 Toward Toxicological Interpretation of Diffusive Gradients in Thin Films in Marine Waters Impacted by Copper**

*J. Strivens, PNNL / Coastal Sciences; R. Johnston, Space and Naval Warfare Systems Center Pacific; G. Rosen, SPAWAR Systems Center Pacific; N. Schlafer, Pacific Northwest National Laboratory / Marine Sciences Laboratory; N. Hayman, Space and Naval Warfare Systems Center Pacific; J. Brandenberger, Pacific Northwest National Laboratory / Marine Sciences Laboratory; R. Gauthier, Space and Naval Warfare Systems Center Pacific; P. Caswell, Puget Sound Naval Shipyard & Intermediate Maintenance Facility; M. Jabloner, H. Jennings, NAVFAC Northwest*

As part of an ambient monitoring program being conducted for the Puget Sound Naval Shipyard & Intermediate Maintenance Facility (PSNS&IMF) in the Puget Sound, receiving waters of Sinclair and Dyes Inlets are routinely monitored for trace metals and toxicity to assess water quality status, track progress in achieving water quality goals, and demonstrate protection of aquatic life. Recently, aqueous metal bioavailability using diffusive gradients in thin film (DGT) passive samplers has been incorporated into the monitoring program. In situ campaigns to record labile ($C_{DGT}$) Cd, Cu, Ni, Pb, and Zn have imbricated DGTs in a manner that allows for response linearity to be defined for deployment times ranging from 24 hours to 14 days in low to moderate ambient conditions, and also in a manner that allows for capture of stormwater related pulses. A current obstacle to regulatory acceptance of $C_{DGT}$ data is validation of an uptake response that reliably mimics that of aquatic organisms. Towards reconciliation of $C_{DGT}$ Cu and natural ligands in respect to toxicity, data shown here correlates ex situ DGT lability of Cu in seawater at varying dissolved organic carbon (DOC) levels to median effective concentration ($EC_{50}$) for *Mytilus* larvae; tantamount to the Marine Biotic Ligand Model. The chronic threshold for $C_{DGT}$ Cu is then applied to gauge the water quality of in situ marine stations monitored over multiple seasons.

**MP221 Development of a novel gas diffusion based passive sampler for monitoring ammonia nitrogen in marine waters**

*L.M. O'Connor Sraj, M.I. Almeida, I.D. McKelvie, S.D. Kolev, The University of Melbourne / School of Chemistry*

Ammonia occurs naturally at low concentrations in aquatic environments, but at elevated levels is highly toxic to aquatic organisms, especially fish. Anthropogenic ammonia pollution of environmental waters has been increasing globally as a result of wastewater plant releases, leaching of ammonia-based fertilizers and agricultural runoff, burning of fossil fuels, and industrial activities. Integrative and passive sampling techniques are an efficient alternative to traditional 'spot' sampling methods, enabling large-scale monitoring programs to assess water quality indicators and the identification of point sources of pollution. Two passive sampling devices (DGT with cation-exchange resin and a polymer inclusion membrane based passive sampler) have been reported for the determination of the time-weighted average concentration ($C_{TWA}$) of ammonium ($NH_4^+$) in freshwaters, but due to interference from alkali and alkaline earth metals in the ion-exchange process neither of these samplers are suitable for monitoring ammonia in marine waters. A passive sampler (PS) based on gas-diffusion across a hydrophobic membrane has been developed and successfully applied for the determination of the $C_{TWA}$ of total ammonia nitrogen in high ionic strength estuarine and coastal waters, for a period of 3 days. This PS is cheap, easy-to-use, reusable, and has a dynamic concentration range of 1.0 – 12 µM ammonia, which covers the water quality guideline trigger value of 11.4 µM (160 µg $L^{-1}$ $NH_3$-N) for high conservation value estuarine and marine waters in Australia. The PS was calibrated under laboratory conditions and deployed in a tank of seawater in the laboratory and at a highly dynamic estuarine site in Port Phillip Bay, SE Australia. Good agreement between passive and spot sampling was achieved in both cases, where the relative error between the concentrations of ammonia nitrogen measured by spot sampling and the corresponding $C_{TWA}$ values was 4.0% for the seawater matrix, and 13.0% for the estuarine site. Membrane permeability and receiving solution optimization studies were performed and the flow pattern effects on ammonia uptake were also examined. Several strategies for extending deployment duration and control of biofouling are under investigation, in addition to a study of the effect of temperature, pH and salinity on the newly developed PS.

**MP222 Testing the effectiveness of stabilized liquid membrane device (SLMD) passive samplers at varying water hardnesses**

*A. Johnson, Western Washington University / Department of Environmental Sciences; T. Norris, J. Kirby, Western Washington University; E. Brown, J.W. Booth, J. Miller, J. Pratt, M. Sanchez, R.M. Sofield, Western Washington University / Department of Environmental Sciences*

The use of stabilized liquid membrane devices (SLMDs) as freshwater passive sampling devices for ionic metals is an emerging passive sampling technique in environmental monitoring. SLMDs are composed of sealed sections of plastic tubing and filled with a mixture of a chelating agent and oleic acid. The oleic acid interacts with calcium and magnesium ions in the surrounding water to create an outer film in which metals can bind to the chelating agent. Due to ease of construction and low cost, SLMDs have the potential to be useful monitors of metal contamination in freshwater. The samplers have been used in the field under a range of conditions, but have only been laboratory tested in very hard water, which is not representative of all freshwaters that the samplers could be deployed in. It is unknown how SLMD sampling effectiveness changes in soft waters, which may not provide enough calcium and magnesium for the samplers to work properly. To address this knowledge gap, we exposed SLMDs in the laboratory to a fixed concentration of copper in very soft, moderately hard, and very hard water using EPA WET testing recipes. The SLMDs were contained in individual test chambers for 32 days in a static renewal test. Every four days, SLMDs were removed to analyze metal accumulation and remaining test chambers were renewed. Preliminary data suggests that copper accumulation rates are similar in soft and moderately hard waters, but this rate is higher in very hard water. Results will be used to guide future use of SLMDs as passive integrative samplers in water quality monitoring and contaminated site cleanup.

**MP223 Stabilized Liquid Membrane Device Chelation Rates for Metals of Differing Valencies**

*J. Kirby, Western Washington University; E. Brown, A. Johnson, Western Washington University / Environmental Sciences Department; T. Norris, Western Washington University; J.W. Booth, J. Miller, M. Sanchez, J. Pratt, R.M. Sofield, Western Washington University / Department of Environmental Sciences*

Stabilized liquid membrane devices (SLMDs) are an emerging type of passive sampler used to test for metals in freshwater environments. SLMDs provide an inexpensive alternative to grab samples when testing for metals in freshwater environments. One of the main advantages over grab samples is that SLMDs can represent an average concentration over time, which minimizes the variability that can result from pulses of contamination in freshwater bodies such as streams and rivers. The ability of SLMDs to detect trace metal concentrations that fall below detection limits of most instruments is another advantage over traditional grab sampling. Because of these advantages, SLMDs could have applications in monitoring for contaminated site cleanup. SLMDs contain a 1:1 mixture of oleic acid and Kelex-100, a metal chelating agent. Previous controlled laboratory studies have established the rate of chelation for cadmium, cobalt, copper, nickel, lead, and zinc, all of which are divalent metals. In this experiment, SLMDs were exposed to metals of differing valences including silver (1+), copper (2+), zinc (2+), and aluminum (3+) to investigate potential differences in binding affinity to the Kelex-100. SLMDs were exposed to individual metals as well as mixtures of the four metals. Testing spanned a 32-day exposure period using a static renewal approach. Samples were taken every 4 days to test metal accumulation over time for a total of 8 time intervals. Dilutions were made with moderately hard reconstituted water from EPA Whole Effluent Testing methods. Preliminary results indicate that Kelex-100 has a high affinity for aluminum and zinc relative to copper and silver.

**MP224 A comprehensive in-situ and ex-situ passive sampling program to investigate freely-dissolved metals, inorganic analytes, OCPs, and PCBs**

*M. Healey, J. Roberts, SiREM; J.M. Conder, L. Wellborn, Geosyntec Consultants*

Passive sampling devices (PSDs) present many advantages over conventional sample collection methods for quantifying hydrophobic organic compound (HOC) and inorganic compound availability in sediment, soil, surface water and storm water in terms of cost and data quality. PSDs provide data to estimate contaminant bioavailability and toxicity to environmental receptors that are more accurate than conventional grab or mechanically-extracted samples, as it quantifies freely-dissolved contaminants. PSDs can be deployed directly in situ to capture the effects of groundwater flux, changes in field conditions and the heterogeneity of a site on the freely dissolved concentrations of the compounds of interest. However, physically deploying PSDs can be difficult in the field depending on the foot or boat traffic in the area, the migratory patterns of animals, the depth of the deployment below the sediment or water surface, the current of water above the PSd or even how often a site can be accessed. In these cases where in situ deployment is not feasible, samples can be collected once from the field and analyzed using ex situ methods. In addition to the above advantages, ex situ experiments can be mixed to decrease deployment times, allowing kinetically slow compounds to be analyzed under shorter time frames and the results of the PSD can be directly compared to the sediment it was deployed in. Ex situ experiments, however, remove the PSD from true field conditions. In this experiment, PSD peepers for metals, ammonia, fluoride analysis were deployed under in situ conditions to surface sediment and deeper sediment samples from an undisclosed site to determine the risk associated with these compounds at the site. Ex situ testing was additionally completed for organochlorine pesticides and polychlorinated biphenyl (PCB) analysis using a polyethylene-based PSD with rare PCB congener performance reference compounds. Discussion comparing the in situ and ex situ deployment will be explored as well as a comparison of the results between the two deployment methods.

**MP225 The development of a passive sampling device to evaluate dissolved oxygen concentration in benthic zone**

*Y. Kameda, Chiba Institute of Technology / Creative Engineering*

Monitoring of the concentration of dissolved oxygen is very important to keep a broad spectrum of benthic organisms, healthy ecosystem and good cycle of nutrients and pollutants in lakes and the sea. In Japan, dissolved oxygen is one of water quality standards in lakes and bays. However, it is very hard work to monitor the DO concentration frequently at many sampling sites and evaluate the spatial distribution. DO sensors are very useful but very expensive. The grab sampling method is less expensive than monitoring by sensors but the data is snapshot data. The DO monitoring will need continuous data for benthic organisms because the aquatic environment in benthic zone is heterogeneous spatiotemporally. This presentation shows a novel monitoring technique to measure DO concentration in benthic zone in lakes and the sea by using a novel DO passive sampler. The passive sampler consists of chemcatcher holder, oxygen absorbent film and diffusion limiting rubber. The color of the film changes according to the absorbed amount of DO. Therefore the absorbed amount can be estimated from the color. The color can be qualified and quantified by low cost color difference meters. Laboratory calibration tests revealed that the absorbed amount of DO increased linearly during the deployment. The calibration tests also revealed sampling rates and effects of flow rate and water temperature to them. After that, this device including a special cage will be applied to lakes and the sea to compare time weighted average concentration of DO by passive samplers with those from continuous monitoring data by using DO sensors. This device is very easy to operate and low cost so that it will be one of useful techniques to monitor spatial distributions and temporal variation of DO concentration in benthic zone in lakes, bays and the sea.

**MP226 Application of Passive Sampling to Measure PCB Microbial Dechlorination Kinetics**

*T. Needham, University of Maryland Baltimore County / CBEE; K. Sowers, University of Maryland Baltimore County; U. Ghosh, University of Maryland Baltimore County / Chemical, Biochemical, and Environmental Engineering*

Progress in developing suitable microbial bioremediation treatments of polychlorinated biphenyl (PCB) in contaminated sediments have traditionally struggled to measure and model the microbial kinetics at environmentally relevant concentrations. To address this issue, we used low-density polyethylene (PE) for passive dosing/sampling and quantified the biological rate of dechlorination of 2,3,4,5-tetrachlorobiphenyl (PCB 61) to 2,3,4-trichlorobiphenyl (PCB 23) by the organohalide respiring bacterium, *Dehalobium chlorocoercia* (DF-1). The biological rates were measured over environmentally relevant concentration ranges of 1.5-40 ng/L aqueous concentration with and without the presence of sediment in bench scale microcosm studies. The rate of dechlorination was determined to be linearly dependent on the initial freely dissolved concentration of PCB 61 both in sediment and sediment free microcosms. Predicted rates of dechlorination based on sediment free microcosms were within a factor of 2 in sediment microcosms. Passive dosing/sampling approach reported in this study, combined with partitioning characteristics of specific sediments, can be used to predict in-situ rates of microbial dechlorination during bioaugmentation or monitored natural attenuation to enable future microbial bioremediation treatment options.

**MP227 Ex Situ Chemical Availability Recontamination Grab Observation (ESCARGO) For Rapid Assessment of Sediment Amendments**

*J.M. Conder, Geosyntec Consultants; R. Adams, Loyola Marymount University / Civil Engineering & Environmental Science; M. Jalalizadeh, M. Vanderkooy, Geosyntec Consultants; J. Carilli, SPAWAR Systems Center Pacific / Environmental Sciences; G.H. Rosen, SPAWAR Systems Center / Energy and Environmental Sustainability*

Approaches to quantify the reduction in chemical availability in sediments amended with solid materials (e.g., sand, dredged material (DM), activated carbon, etc.) can involve complicated, expensive, and time-consuming bench- or pilot-scale evaluations. These evaluations often do not (or cannot) evaluate the long-term conditions in which the solid amendment has been fully or partially mixed with underlying contaminated sediment through bioturbation or other natural processes. In response to these challenges, we devised and tested a rapid method to assess the long-term reduction of chemical availability gained from solid amendments: the *Ex Situ* Chemical Availability Recontamination Grab Observation (ESCARGO). The ESCARGO approach combines a small sample of unamended site sediment (~10-50 g, dry weight), the sediment amendment(s) of interest, and a polyethylene (PE) passive sampler under agitated conditions for 28 days. Following the equilibration period, the PE is analyzed to measure concentrations of freely-dissolved organic chemicals. Three treatments are assessed: 1) an unamended sediment; 2) a 10% sediment/90% amendment mixture to represent "short term" remedy performance; and 3) a 40% sediment/60% amendment mixture to represent "long term" remedy performance. The ESCARGO approach was applied to evaluate the reduction in PCB availability for a sediment in Pearl Harbor amended with 3 amendments (sand, and two DMs with 0.44% and 0.99% Total Organic Carbon (TOC) contents). ESCARGO short term results indicated that the higher carbon DM reduced available PCBs by an average (SD) of 81% (± 5%), performing better than the lower carbon DM and sand (reduction in PCB availabilities of 51% (± 6%) and 45% (± 9%), respectively). ESCARGO long-term results also indicated superior performance of the higher carbon DM, but indicated slightly lower reductions in PCB availability, as compared to the short term results (reduction in PCB availabilities of 66%, 39%, and 37% for higher carbon DM, lower carbon DM, and sand, respectively). Results suggest additional PCB binding capacity of the higher carbon DM compared to the sand and lower carbon DM, and project long-term reduction in PCB availability. The ESCARGO approach is a rapid and inexpensive method to compare the site-specific performance of multiple contaminated sediment amendments and provide a prediction of their long-term performance.

**MP228 Use of ex situ passive samplers to measure freely dissolved PAHs in sediments at a former manufactured gas plant site**

*S.B. Kane Driscoll, Exponent, Inc. / EcoSciences; S. Ahn, Exponent, Inc. / Environmental and Earth Science; J. McGrath, Exponent Inc. / EcoSciences; A. Schierz, Exponent Inc. / Institute for Resource Ecology at the Helmholtz-Center Dresden Rossendorf; J. Romer, J. Clock, EPRI*

Concentrations of freely dissolved polycyclic aromatic hydrocarbons (PAHs) in sediment porewater have been shown to be related to the bioavailability of sediment-associated PAHs to aquatic organisms. The objective of this work was to demonstrate the use of passive samplers in the laboratory (*ex situ*) for measuring the concentration of freely dissolved PAHs in porewater from impacted sediment at a former manufactured gas plant site. Nine samples of surface sediment were each homogenized and split for 1) analysis of bulk sediment for 34 PAHs, total organic carbon, and black carbon and 2) exposure to polyethylene (PE) passive samplers in the laboratory. Pre-cleaned PE strips were added to sediment slurries in 500-mL glass jars and placed on a shaker table for six weeks. At the end of the sixth week, PE strips were retrieved, cleaned, and extracted immediately. Freely dissolved PAH concentrations in porewater were calculated from concentrations in PE using PE-water partition coefficients and compared to porewater concentrations predicted from equilibrium partitioning models. Results indicate that concentrations measured using passive samplers are lower than concentrations estimated using standard sediment organic carbon to porewater partition coefficients ($K_{oc}$), but higher than concentrations estimated using a partitioning model that incorporates sorption to both natural sediment organic carbon and black carbon. The Sum of Toxic Units (Sum-TU) based on concentrations of 34 PAHs in bulk sediment >1 indicates further assessment is warranted for these sample locations, but the Sum-TU based on concentrations of PAHs measured using passive samplers < 1 indicates concentrations of PAHs in these samples are acceptable for the protection of benthic invertebrates. These results indicate that *ex situ* passive samplers 1) can be used to measure concentrations of freely dissolved PAHs in porewater and 2) may provide a more accurate measurement of concentrations of bioavailable contaminants, which can be used to “screen out” samples or areas of a site that require no further analysis of risk.

**MP229 Performance Evaluation of an Engineered Sediment Cap for Chemical Isolation Using In Situ SPME Passive Samplers**

*M. Kanematsu, D.R. Opdyke, D. Vlassopoulos, K. Russell, Anchor QEA*

An engineered sediment cap was installed after dredging 10 feet of glacial till contaminated by polychlorinated biphenyls (PCBs) to prevent leaching of remaining PCBs from underlying material in the River Raisin. The cap consists of a 1-foot chemical containment layer (CCL) comprising sand and organoclay to isolate PCBs, overlain by a gravel filter layer topped with armor stone. Following cap placement, porewater monitoring was performed to verify the integrity and effectiveness of the CCL. For porewater monitoring, three sand-filled monitoring ports were installed at different locations in the cap through the filter and armor layers. One year after placement, in situ solid-phase microextraction (SPME) passive samplers were deployed in the monitoring ports to measure PCB concentrations in the porewater just above the CCL. Each SPME sampler consisted of a 5-foot-long custom-designed push-point sampler holding two SPME fibers (4 inches long with a 35-micron-thick polydimethylsiloxane coating) and was designed to allow porewater to contact the SPME fibers while also preventing vertical preferential flow paths inside the sampler. Because highly hydrophobic PCB congeners may require months or even years to reach equilibrium between the fibers and surrounding porewater, the SPME fibers were spiked with six $^{13}C$-labeled PCBs prior to deployment as performance reference compounds (PRCs) to provide information about site-specific mass transfer kinetics of PCBs. At the end of the deployment period (105 days), the SPME samplers were successfully retrieved without damage. An external resistance model, based on Lampert et al. (2015) and Fernandez et al. (2009), was fit to the PRC data to estimate site-specific mass transfer rates for all measured PCB congeners. The estimated total PCB (TPCB) porewater concentrations in the three monitoring ports were similar to the TPCB concentrations in the overlying water column (measured using semi-permeable membrane devices), which is consistent with expectations, given that surface water was entrained in the monitoring ports during sand placement. The porewater TPCB concentrations were substantially lower than the TPCB concentrations in the pre-construction sediment porewater. These results demonstrate that the CCL is performing as designed and limiting migration of PCBs to the water column. Installation of the monitoring ports and custom-designed SPME samplers allowed successful porewater sampling in the sediment cap.

**MP230 Application of passive sampling for quantification of sources and sinks of PCBs and OCPs in the Anacostia River**

*M. Bokare, N. Lombard, S. Magee, University of Maryland Baltimore County / Department of Chemical, Biochemical and Environmental Engineering; T. Wilson, USGS; U. Ghosh, University of Maryland Baltimore County / Chemical, Biochemical, and Environmental Engineering*

Polychlorinated biphenyls (PCBs) and organochlorine pesticides (OCPs) are major contaminants of concern in the Anacostia River, resulting in fish-consumption advisories in District of Columbia (DC). To quantify the sources and sinks for these pollutants, polyethylene (PE) passive samplers were deployed at several locations in DC to measure the freely dissolved surface water and sediment porewater concentrations of OCPs and PCBs. Passive samplers were also concurrently deployed at 5 locations in Washington DC to measure the gas-phase concentrations. Our initial results show that the freely-dissolved PCB concentrations in the water column across the sites varied from 0.01 – 6.5 ng/L while measured OCP concentrations were in the range of 0.22 – 8.4 ng/L during the deployment period from March to July 2017. During the same period, gas phase PCB concentrations ranged from 208 – 1015 pg/m$^3$, while gas-phase OCP concentrations were in the range of 80 – 122 pg/m$^3$ across the sites. The water-air exchange flux for PCBs and OCPs over the Anacostia River was calculated to be +282 ng/m$^2$/day and +207 ng/m$^2$/day respectively, resulting in volatilization of about 355 g of PCBs and 260 g of OCPs per year from the Anacostia river. Measurements of dissolved and particulate organic carbon (DOC and POC, respectively) and direct measurements of PCB and OCP concentrations on suspended sediments are being used in combination with streamflow data from United States Geological Survey (USGS) to calculate incoming pollutant loads from major tributaries and branches of the Anacostia river and the net pollutant outflow from the Anacostia into the Chesapeake Bay. The pollutant transfer rates between sediments and overlying water due to diffusive flux are also being quantified. Data analyses are ongoing for samples taken through a full one-year cycle to quantify seasonal differences that will allow a complete understanding of the annual pollution budgets for the Anacostia River.

**MP231 Evaporative Emissions of Polycyclic Aromatic Compounds from Alberta’s Oil Sands Tailings Ponds Water**

*R. Robitaille, University of Toronto / Earth Sciences; L. Jantunen, Environment and Climate Change Canada; M.L. Diamond, University of Toronto / Department of Earth Sciences; T. Harner, Environment and Climate Change Canada / Air Quality Research Division; A. Abdollahi, Trent University / Department of Chemistry*

Polycyclic aromatic compounds (PACs) are semi volatile organic compounds and emitted from Alberta’s oil sands tailing ponds (OSTPs). These compounds are important because they are known to pose health hazards and be atmospherically transported to non-source regions. Water samples

taken from the ponds in the summers of 2016 and 2017 were analyzed for PAH and alkylated-PAHs, additionally they were screened for nitro and oxy-PAHs. Preliminary results indicate the levels of alkylated-PAHs are higher than PAHs by about an order of magnitude. . These open-aired ponds are shallow and have a large surface areas, thus organic compounds can easily volatize into the atmosphere. Evaporative emissions of PACs from these ponds are estimated using air-water partition coefficient values determined under ideal conditions (i.e., de-ionized water) and may have associated artifacts from the methodology. OSTP water is a complex mixture containing compounds that might affect these partitioning values. So an equilibrium chamber study was devised to more appropriately determine the air-OSTP water partition coefficients for PACs. This chamber study setup used ethylene vinyl acetate (EVA) polymer as a thin-film passive sampler for fugacity measurements of PACs in air and water. This same experiment was successful using deionized water for the distribution of PAHs between air and water. We will present the levels of PACs in OSTP waters, the results of the chamber experiment using the complex mixture of OSTP waters and estimate the net emissions of PACs from OSTPs using paired water and passive air samplers.

**MP232 Assessing the atmosphere-surface exchange of gaseous elemental mercury using passive air samplers**

*F. Wania, M. Feigis, S. Mistry, M. Snow, C. Mitchell, Y. Lei, University of Toronto / Physical and Environmental Sciences*

The specific properties of gaseous elemental mercury (GEM) allow it to undergo bidirectional exchange between the atmosphere and the Earth's surface. Determining the direction and the magnitude of GEM's atmosphere-surface flux is possible and has been accomplished using micrometeorological and chamber techniques, but is (i) complex and labor intensive, and (ii) often only yields fluxes over relatively short time scales. A recently developed passive air sampler for GEM may have the precision required for identifying and quantifying vertical concentration gradients above the Earth's surface and therefore the direction and size of exchange fluxes at much longer time scales of weeks to a year and with much less effort and lower cost than existing approaches. We tested the feasibility and performance of this approach by measuring concentration gradients for one year with a monthly resolution above both natural soil in a forest and a nearby clearing, as well as above soil artificially contaminated with inorganic mercury. Significant gradients of GEM air concentrations, both increasing and decreasing with height above ground, were observed and found to be dependent on soil contamination, temperature, snow cover and solar irradiation. Because the sampler's uptake kinetics has a known, small dependence on wind speed, sampled amounts of Hg that decrease with increasing proximity to the soil surface could be an artifact caused by wind speed gradients. Measurements, however, reveal that wind differences above the soil are insufficient to explain the differences in the sampled amounts with height, implying that deposition of GEM can be recorded with this method. The method holds promise to also find use for the measurement of GEM fluxes between atmosphere and vegetation, e.g. in forest and tundra ecosystems.

**MP233 Development of guidelines for use of passive sampling devices for natural resource damage assessment and restoration**

*H. Forth, Abt Associates; S.E. Allan, NOAA / Office of Response and Restoration; M. Steinhoff, DOC / NOAA / Office of Response and Restoration; R. Lohmann, Graduate School of Oceanography, University of Rhode Island, Narragansett / Chemical Oceanography*

Passive sampling devices (PSDs) are an effective, fit-for-purpose technology that offer an alternative to conventional sampling techniques for characterizing bioavailable contaminant concentrations in aquatic environments. Recent improvements and validation of methods to quantify aqueous concentrations from PSDs, especially for nonpolar PSDs, as well as additional standardization and validation of passive sampling methods have transformed PSDs into a robust, quantitative technique. While PSDs have the potential to become an integral part of the National Oceanic and Atmospheric Administration Assessment and Restoration Division's (NOAA/ARD's) "toolkit" for conducting natural resource damage assessments (NRDAs) at waste sites and oil spills, general unfamiliarity with the methods and lack of specific guidelines have prevented widespread adoption. The main objective of this study is to develop guidelines on the use of PSDs in NRDA to enable the uptake of this technology within ARD. The aim is to help ARD project managers determine when PSDs may be useful during an assessment or restoration monitoring and if useful, to provide the resources and information needed to help implement passive sampling successfully at NRDA waste and oil spill sites. In determining if PSDs are suitable for a particular site characterization or exposure or injury assessment, we discuss common NRDA data quality objectives and how PSDs could be used to address them. For these initial guidelines, we chose to focus on low density polyethylene (LDPE) membrane PSDs since they are well-established, readily available, easy to use, low cost, and are supported by commercial analytical laboratories. For LDPE PSDs, we describe the methods for preparing and analyzing PSD samples, as well as identify several commercial laboratories that can help with these steps. We also provide protocols for deploying and retrieving PSDs in the field, presenting examples of different sampler and deployment configurations. We discuss deployment timing and sampling design, especially as it relates to different waste site and spill scenarios where contaminant concentrations may be changing with time. Finally, we provide procedures needed to process and interpret the data. These guidelines aim to bridge the gap between research and application by end-users in the context of the specific needs and objectives of NRDA.

**MP235 Modeling the impacts from non-linear sorption to the behaviors of PRCs and target compounds in passive sampling**

*X. Shen, Texas Tech University / Environmental Engineering; S. Yan, Texas Tech University / Chemical Engeneering; D.D. Reible, Texas Tech University / Civil and Environmental Engineering*

In the past decade, passive sampling with organic polymers has been used for the assessment of bioavailability of hydrophobic organic contaminants in sediment. Performance reference compounds (PRC) have been considered as a reliable calibrating approach for estimating uptake rates of the target contaminant in non-equilibrium passive sampling. The traditional use of PRCs is to assume that the sorption of a target compound and desorption of its corresponding PRC follow the same rate. With nonlinear sorbents such as activated carbon mixed into sediments, PRCs do not exhibit desorption rates equivalent to similar compound uptake rates and the difference is a function of compound concentration and the nonlinearity of the sorbent sorption. In this presentation, a one-dimensional diffusion model with non-linear sorption has been developed to study the impacts from the non-linear sorption to the asymmetric behaviors of PRCs and target compounds. The numerical simulation of the model is performed by CapSim – a robust numerical modeling tool, and the simulated results are compared both qualitatively and quantitatively to experimental data from recent studies that observed the asymmetric behaviors. The presentation provides estimates of the errors in assuming reversible sorption and desorption and how to limit those area through property control of PRC loading of the passive sampler. When PRC loading cannot be controlled, a methodology for correction will be presented. The results will be applied to measure porewater concentrations of PCBs at several sites where activated carbon has been used to manage bioavailability.

**MP236 Evaluating partition-based sampling for predicting the bioaccumulation of hydrophobic organic contaminants by higher trophic level organisms**

*S.N. Schmidt, Technical University of Denmark / Atlantic Ecology Division; R.M. Burgess, USEPA / Atlantic Ecology Division*

Recent research has shown that bioaccumulation of hydrophobic organic compounds by benthic and sessile marine organisms can be accurately predicted by partitioning-based sampling (within a factor of 10). In these lower trophic level organisms, bioaccumulation can thus be explained by equilibrium partitioning. Now, research is needed to assess the ability of partitioning-based sampling to estimate bioaccumulation by pelagic and mobile organisms (i.e., by higher trophic level organisms). The limited available research on the topic states that processes beyond simple equilibrium partitioning need to be taken into consideration to accurately estimate bioaccumulation by these organisms. Generally, two partitioning-based (passive) sampling approaches are used: (1) the *ex situ* equilibrium sampling approach fully equilibrates a thin polymer with sediment during tumbling in the laboratory and (2) the in situ pre-equilibrium sampling approach places a thicker polymer within the bulk water or sediment on site and then infers equilibrium concentrations through the use of performance reference compounds (PRCs). As noted above, the equilibrium polymer concentrations can be used as a surrogate predictor of bioaccumulation in lower trophic level organisms. In addition, freely dissolved concentrations ($C_{free}$) can be determined as the ratio of the equilibrium concentrations in the polymer and polymer to water partition ratios. The current study reviews existing literature linking partitioning-based sampling data and bioaccumulation by higher trophic level shellfish and fish. The equilibrium polymer concentrations and $C_{free}$ determined by partitioning-based sampling are incorporated into bioaccumulation models to predict wet weight concentrations, lipid-normalized concentrations and chemical activity in higher trophic level organisms. Ideally, this research will provide an assessment of the ability to predict bioaccumulation by higher trophic level organisms using partitioning-based sampling approaches. If successful, this research will serve as a tool for regulatory agencies (e.g., USEPA) to assess risk associated with contaminated sediments in terms of their potential to contaminate commercially and recreationally important shellfish and fish.

## Advances in Sediment Quality Assessment for Regulation and Management

### MP237 An Absorption Sink Coupled with Isotope Dilution Method for Improved Assessment of Bioavailability of Organic Pollutants

*X. Li, University of California, Riverside; J. Gan, University of California, Riverside / Environmental Science*

The use of bulk chemical concentration for environmental risk assessment of hydrophobic organic contaminants (HOCs) in soil or sediment is considered to overexpress their ecotoxicity, as HOCs have high affinity for solid particles and irreversible sorption. The measurement of bioavailability of HOCs is important for improving their risk assessment. Biological methods such as bioaccumulation offer direct measurement of bioavailability, but they are often expensive and extremely time-consuming. Several chemically based methods for assessing the bioaccessibility of HOCs have been developed. Isotope dilution method (IDM) is a relatively new method, which makes the use of the identical properties and behaviors of target analytes and their isotope labeled counterparts. However, in the conventional protocol of the IDM method, usually only a subsample of the aqueous phase was used for analysis to derive the ratio of the target analytes and their isotope labeled analogues following GC-MS analysis. For strongly hydrophobic compounds, this method often lacks sensitivity and reproducibility because the analytes are predominantly in the solid phase. In the current study, we introduced an absorption sink (e.g., silicone rod, polyethylene film) in the IDM method to increase the quantity of target and isotope labeled analytes for analysis. After mixing, the absorption sink was removed and extracted with an organic solvent before analysis. This simple modification showed a significant improvement in the sensitivity and reproducibility of IDM for a range of HOCs including DDTs and PCBs in soils and sediments.

### MP238 Removing Tenax system dependence during contaminant risk evaluation through phase volume normalization

*S. Nutile, Penn State Univ. / The Behrend College / Biology; A.D. Harwood, Alma College / Environmental Studies / Biology; F.L. Sinche, Southern Illinois University, Carbondale / Center for Fisheries Aquaculture and Aquatic Sciences*

Tenax extractions estimate exposure risk of sediments contaminated with hydrophobic organic compounds (HOCs) by measuring the chemical fraction that is and will become available for exposure. Normalizing Tenax extractable concentrations for sediment organic carbon (OC) corrects extractable concentrations for the environmental fraction controlling bioaccessibility, allowing for rapid screening of bioaccumulation risk. This normalization, however, encumbers this technique with a system dependence absent from similar chemical extraction methodologies, such as passive samplers. Passive sampler concentrations are normalized for the phase volume of the sorbent coating the device, such that representing chemical to sampler partitioning is independent of the extraction system. As such, implementation of this methodology in risk assessment is straightforward. Normalizing Tenax extractable concentrations for the Tenax phase volume similarly to passive samplers would remove the Tenax system dependence, extending applicability in environmental risk assessment. The objective of the current study was to mathematically determine the Tenax phase volume, and compare Tenax phase volume normalization to OC normalization in relation to estimating bioaccumulation using single-point Tenax extractions. Based on the surface area of 35 $m^2$ for 1 g of Tenax, the calculated Tenax phase volume was equal to 5.9 L/g Tenax. Normalizing Tenax extractable concentrations from previous studies for the Tenax phase volume used during single-point Tenax extractions and comparing these values to bioaccumulated tissue concentrations of aquatic invertebrates yielded linear regressions similar to those generated with OC normalization. The correlation coefficients, parameters of the regression lines, and statistical significance of the regressions did not change when normalizing Tenax concentrations for phase volume or sediment OC within studies. Combining data from the previous studies in a single regression did not significantly affect the estimates of bioaccumulation based on Tenax extractable concentrations normalized for phase volume or OC, meaning Tenax phase volume normalization comparably corrects Tenax extractable concentrations to OC normalization. Without measuring OC content of sediment prior to estimating HOC contamination risk, Tenax offers a rapid, cost-effective, and reliable means of screening contaminated sites during environmental risk assessments.

### MP239 Influence of Complex interactions between Tubificid Oligochaetes and Bivalves on Metal Bioavailability in Multi-metal Contaminated Sediments

*M. Xie, The Hong Kong University of Science and Technology / Shenzhen Research Institute; S.L. Simpson, CSIRO Land and Water / Centre for Environmental Contaminants Research; W. Wang, Hong Kong University Sci. Technol. / Department of Ocean Science*

Biological activities by benthic organisms perturb the physical, chemical and biological structures of sediments, modifying the fate of metal contaminants within and the release from sediments. Quantifying the influence of bioturbation on contaminant bioavailability is important for assessment of sediment quality and associated contamination risk. In the present study, we studied the effects of bioturbation on efflux of metals from multi-metal contaminated sediments, with particular emphasis on the interplay between organisms belonging to different functional groups. Multi-metal contaminated sediments with in situ living oligochaetes *Limnodrilus hoffmeisteri* were collected from the field, incubated and stabilized under the laboratory condition for three months to reconstruct a steady biogeochemical structure within the sediment. The bivalves, *Corbicula fluminea*, were then introduced into the mesocosm at different densities. Metal concentrations in the overlying water were monitored daily for a period of 8 days. Diffusive gradients in thin film (DGT) probes were deployed at the end of the experiment to determine the in situ porewater metal concentrations. Total dissolved metal fluxes were determined based on metal concentrations in the overlying water and the diffusive fluxes were derived based on the porewater profiles. The results indicated that the interplay between the two groups of organisms enhanced the release of Mn, Co, Ni and Zn. Efflux of Mn, Co, Ni and Zn were also significantly elevated, with bioturbation induced efflux significantly higher than the diffusive efflux. However, the mobilization and efflux of Cu and Cr were not significantly different between treatments and was attributed to the higher affinities of these two metals to the solid phase resulting in lower mobility of Cu and Cr. Overall, our study demonstrated that the responses of different metals to the same bioturbation behavior was different, resulting in distinct mobility and fate of metals in the sediment, and modifying the bioavailability to the main bioturbating organisms and cohabiting organisms.

**MP240 Effects of physico-chemical characteristics of formulated sediment on the survival and growth of amphipods *Grandidierella japonica* and *Hyalella azteca***

*K. Hiki, National Institute for Environ. Studies / Center for Environmental Risk Research; F. Nakajima, T. Tobino, The University of Tokyo / Department of Urban Engineering; H. Watanabe, H. Yamamoto, National Institute for Environmental Studies / Center for Health and Environmental Risk Research*

Spiked sediment toxicity tests are necessary for the hazard/risk assessments of hydrophobic chemicals or substances strongly binding to sediment. In the spiked sediment tests, the use of formulated sediment is occasionally preferred rather than field-collected sediment because of its higher reproducibility and availability regardless of seasons and places. Although several types of formulated sediment have been proposed, little is known about the effects of physico-chemical characteristics of formulated sediment (e.g., particle size distribution and types of organic matter) on amphipods and thus it is still unclear about what is the best formulated sediment. In this study, we investigated the applicability of several types of formulated sediment using a freshwater amphipod *Hyalella azteca* and an estuarine amphipod *Grandidierella japonica*. As a preliminary experiment to investigate the effects of particle size distribution on amphipods, we performed 10-day survival and growth tests of formulated sediment comprising of quartz sand and kaolin using *G. japonica*, with changing the proportions of kaolin as silt and clay particles (0, 5, 10, 25, 50, and 100%). Our experiments demonstrated that while all formulated sediment sample was not lethal toxic (mortality < 10%) to *G. japonica*, the body length increment of surviving amphipods was significantly different among the proportions of kaolin. The increment was the highest in the sediment comprising of 5% to 10% kaolin, and was decreased with increasing kaolin proportions. Based on these results, we hypothesized that standardized formulated sediment containing large proportions of silt and clay (about 20%) is not always appropriate for amphipod toxicity tests. To validate the hypothesis, we conducted the same experiments using *H. azteca*. In addition, we will present the results comparing several standardized formulated sediment samples (e.g., ISO, USEPA, and OECD) using survival and growth tests of *H. azteca*, and investigate the effects of differences in organic matter (e.g., peat moss and α-cellulose) and the other ingredients on the amphipod.

**MP241 Sediment Toxicity Testing at a Reduced Temperature: Diagnostic Results from California's Stream Pollution Trends (SPoT) Monitoring Program**

*B.M. Phillips, S. Zamudio, B.S. Anderson, University of California, Davis / Environmental Toxicology; J. Voorhees, Marine Pollution Studies Laboratory / Environmental Toxicology; K. Siegler, L. McCalla, R.S. Tjeerdema, University of California, Davis / Environmental Toxicology*

The Stream Pollution Trends Program (SPoT) is a statewide sediment toxicity and contaminant monitoring program that is part of California's Surface Water Ambient Monitoring Program (SWAMP). Since 2008, SPoT has monitored integrator sites in up to 100 watersheds for toxicity to the amphipod *Hyalella azteca* and a number of current-use and legacy contaminants. Amphipod toxicity has remained consistent with approximately one in five monitored sites significantly toxic every year. The observed toxicity is significantly related to urban land use and concentrations of pyrethroid pesticides. The relationship between toxicity and pyrethroid pesticides was confirmed, in part, by synoptically testing a subset of samples at two different temperatures. Pyrethroids become more toxic as temperature decreases, so tests were conducted at the standard temperature of 23°C, as well as at 15°C. This lower temperature better represents the average temperature for surface waters at SWAMP sites between 2001 and 2010, which was 15.8°C. Between 2010 and 2016, 194 samples were tested at both temperatures. Significant toxicity was observed in 21% of the samples tested at 23°C, whereas 59% of the samples were significantly toxic at 15°C. Samples containing greater than five organic carbon-corrected toxic units of total pyrethroids were generally toxic to *H. azteca*. Testing at 15°C shifts the toxicity threshold to a lower value. This data set demonstrates the utility of this pyrethroid toxicity screening tool on a large scale. These data also suggest that the potential for surface water toxicity is likely underestimated in SPoT watersheds based on assessing toxicity at the standard protocol temperature.

**MP242 Evaluation of sediment toxicities in the Ariake Sea, Japan, using marine medaka embryos**

*S. Uno, Kagoshima University / Faculty of Fisheries; M. Yamashita, Kagoshima University; E. Kokushi, Kagoshima University / Education and Research Center for Marine Resources and Environment; M. Kawano, Kagoshima University / Faculty of Fisheries*

Chemicals derived from human activities have been carried to the sea area by river water, rainfall, and other factors, and then are settled on sediments finally. They could have individual or multiple effects to the benthic animals, but their actual effects are almost unknown. Recently, we have been developing new method for the evaluation of sediment toxicities collected from the field, using embryos of Java medaka (*Oryzias javanicus*) as marine fish. Because ithe embryos are kept on the polluted sediment only with slight pore water and without overlying water, this can evaluate the toxicities in sediment alone. The Ariake Sea is located in western part of Kyushu, Japan, and has huge area of tidal flats. Although the abundance of aquatic organisms, such as mudskipper fish, crabs, clams, and others, inhibits there, they has dramatically decreased in recent years. Some researchers reported the chemical distributions in sediments of the Ariake Sea, for example, persistent organic pollutants as polychlorinated biphenyls, endocrine disrupter chemicals, and others. However, there have been no examinations on the sediment toxicities to aquatic organisms. In the present study, we collected the field sediments at 12 locations along the shoreline of the Ariake Sea in December 2016. and evaluateed sediment toxicities using the embryos of Java medaka The dried sediment samples were rinsed with an embryo raring mediums. Ten embryos were embedded in half of them in sediment, which was laid at a glass petri dish with 35 mm of diameter, and were developed on the sediment for 12 days post-fertilization. In the period, the rearing water was not added to the dishes. Three dishes contained the sediment were prepared as sampling site (n=3). An embryo was then individually transferred in a hole of 48-well microplates containing artificial sea water, and kept until 3 days after hatching. In this evaluation, sediments collected at 2 locations (mouth of Shiota River) in northeast of the sea were killed 96.7% of embryos. Additionally, the mortality rates of 40 – 77 % were observed in sediments collected from the mouths of Kise, Hattae, and Chikugo Rivers. These perhaps resulted that some toxicants drifting with river flowing and settling on sediments of the river mouth affected to embryos. Our evaluations suggest that sediments at some locations of the Ariake Bay seriously affect to aquatic organisms.

**MP243 Organophosphate esters in the marine sediments of the Palos Verdes Shelf: Spatial and temporal trends**

*J. Li, J. Gan, University of California, Riverside / Environmental Science*

Organophosphate esters (OPEs) are an important class of flame retardants that have extensively used for recent decades. In this study, we measured the concentrations of 10 OPEs in surficial sediments collected from 44 locations at the Palos Verdes Shelf Superfund site off the coast of Los Angeles, and three sedimentary cores were used to understand the temporal trend of their contamination. In the surficial sediments, OPE concentrations ranged from 2.03 to 277 ng/g, and exhibited a logarithmical decrease with relation to the distance from the effluent outfall of wastewater treat plant (WWTP). The strongly hydrophobic OPEs tended to accumulate in offshore areas, whereas the less hydrophobic OPEs appeared to accumulate in inshore areas. The ratios of OPE concentrations between offshore and inshore sites were negatively related to their log Kow values. The sediment cores were dated using $^{210}Pb$, and levels of OPEs in the sediment initially increased during 1940-1970s, and then subsequently decreased in the 1980s. This variation coincided with the historical emission of effluent and suspended solids from WWTPs. After the 1990s, another increase in OPE concentrations was observed and their increase was more pronounced compared to PBDEs. This finding likely reflected the increasing demand for OPEs as the replacement for legacy flame retardants such as PBDEs in the U.S. The ratios of metabolites/parent compounds, including BBOEP/TBOEP and BDCIPP/TDCIPP, were calculated. The ratios showed active in situ natural transformations. This study showed that WWTPs and other urban emissions of OPEs have resulted in the accumulation of OPEs in the marine environment, from where these persistent contaminant may participate in the global ocean cycle.

### MP244 Weight of Evidence Approach for Benthic Metals Assessment

*N. Judd, B.A. Bergquist, D.K. DeForest, R.C. Santore, J. Toll, Windward Environmental, LLC*

At sediment sites with metals contamination, data collected for the purpose of evaluating benthic organism exposure to metals (i.e., exposure data) may include bulk sediment chemistry, excess simultaneously extracted metals (SEM) in sediment, and dissolved metals concentrations in porewater. Also for use at such sites, multiple approaches are available to assess toxicity, such as sediment quality guidelines (SQGs), excess SEM, and other types of equilibrium partitioning sediment benchmarks (ESBs) for sediment-related exposures, including ambient water quality criteria (AWQC), bioavailability-based regression models, and porewater biotic ligand models (BLMs). When the different exposure data are linked with the different toxicity assessment approaches, the result is multiple lines of evidence (LOEs) that can be used to evaluate hazards from metals in sediment and porewater at a particular location. We applied the US Environmental Protection Agency's (EPA's) 2016 *Weight of Evidence in Ecological Assessment* framework to weigh multiple LOEs for evaluating hazards to benthos from metals. Assuming all sediment and porewater data were of acceptable quality, the relevance, strength, and reliability of each LOE was evaluated—including evidence describing expected chemical interactions in a mixtures-toxicity framework—and assigned a qualitative score. Evidence considering bioavailability received higher relevance and strength scores because the relevant form was considered and association with the causative agent was high; evidence considering mixture effects received higher relevance and reliability scores because this evidence better reflects environmental exposures and is consistent with understanding of common mechanisms of metals toxicity. Evidence relying on correlative, rather than causative, toxicity information received lower strength and reliability scores. We found that EPA's weight of evidence (WOE) framework facilitates the logical synthesis of evidence to support conclusions. This WOE approach for the assessment of hazards to benthos from metals will prove useful in understanding the limitations of conclusions drawn from weaker evidence and in prioritizing efforts to obtain additional information (e.g., bioassays, ecological community data, etc.)

### MP245 Site-Specific Sediment Criteria: A framework for using bioassays as a tool for risk assessments

*P. Arth, Enthalpy Analytical / Nautilus Environmental / Aquatic Toxicology; J. Hedgecock, Aecom Technology Corporation*

As part of the risk assessment framework, sediment constituent loads are often compared to common, but loosely relevant, benchmark levels as part of determining the potential for an impact to biological life. There are several technical and regulatory scenarios that benefit from the development of site-specific sediment criteria, including constituent- or condition-specific information gaps or the lack of observed biological response in previous monitoring. Bioassays have the ability to serve as a powerful, integrated tool to support a decision maker's weight-of-evidence approach. The participation of scientists with expertise in bioassay methods and their proper adaptation and interpretation are invaluable to a risk assessment team as they develop goals and plan sampling and analysis design. Site-specific criteria can be calculated using sediment amendment (i.e., spiking studies) and subsequent biological evaluation to more fully characterize local conditions as well as the viability of potential remediation alternatives. When undertaking these studies, multiple factors critical to understanding the design should be considered during planning stages, well before execution of any field work. This presentation aims to provide context, applications, and considerations for bioassay testing as it relates to risk assessment beyond a typical monitoring regime. A case study will form the basis for highlighting key elements and reviewing considerations and variables that should be addressed to ensure a positive outcome and successful regulatory participation and acceptance. We will break apart and explain aspects and elements of the design, small and large, which can be the difference that leads to successful execution and acceptance of the data. From a regulatory standpoint, clear study design and early, frequent communication are paramount to gaining acceptance of both the assessment and subsequent implementation plans. Test design should contemplate a number of physical and chemical elements which include but are not limited to: formulation/speciation of the target compound, parameters for sediment amendment, media for amendment, fidelity of site water/sediment chemical parameters, and method modifications to address site-specific conditions. The ability to understand and communicate the importance of these factors during the planning stage increases the likelihood of acceptance for the proposed plan and, later, results and recommendations.

### MP246 Evaluating Risk in Freshwater Mining Sediments of Tasmania

*W.T. Mehler, University of Melbourne / Zoology; B. Gagliardi, The University of Melbourne / School of Biosciences; V.J. Pettigrove, The University of Melbourne / Sciences; M.J. Keough, The University of Melbourne / School of Biosciences*

Mining-impacted aquatic systems could be at risk from various pollutants, including heavy metals, sulfate, and acidic pH. The present study first evaluated toxicity of stream sediments downstream of metal mines in western Tasmania using a conventional contaminant-based approach (i.e. comparing chemical concentrations to published literature and then comparing this observations to observed toxicity). In this study, we used two native Australian species, *Chironomus tepperi* (midge) and *Austrochiltonia subtenius* (amphipod), to evaluate toxicity of site sediments. Results from these bioassays showed that many of the aquatic systems in Western Tasmania were negatively impacted by current and historic mining activities. Interestingly, the two species showed differing toxicity responses; which may have been the result of different species sensitivities or experimental conditions—suggesting that methods and species sensitivity would need to be considered carefully in future risk evaluations in this area. These sediments were also chemically evaluated for a suite of metals as well as sulfate. This evaluation, coupled with the observed pH in bioassays, provided only a limited understanding of causality (as all three contaminants appeared to be causing risk). As such, we attempted to better understand risk using modified whole-sediment TIE techniques, wherein a cationic resin (to characterize metals toxicity) and an anionic resin (to characterize sulfate and acidic pH toxicity) could be used to better understand causality. Unfortunately, the complex and linked nature of the pollutants (namely acidity driving metals toxicity) in these site sediments meant even this technique could not resolve the activities of the respective pollutants, and overall did not elucidate the causal nature of toxicity. The current presentation will outline the pitfalls of using the conventional approach as well as the strengths, current limitations, and future directions of using TIE techniques for mining sediments.

## Predictive and Statistical Toxicology

**MP247 Assessing the effects of silver nanoparticles on ARPE-19 cells via high content imaging-based phenotypic profiling**

*A. Goldstein-Plesser, ORISE at USEPA / Office of Research and Development; J. Nyffeler, C. Willis, J. Harrill, USEPA / NCCT; W. Boyes, USEPA / ORD*

Efficient methods are needed to evaluate the human and environmental health effects of silver nanoparticles (AgNPs). A high content imaging-based phenotypic profiling approach was used to determine the effects of 12 types (4 sizes x 3 coatings) of AgNPs on organelle morphology in human retinal pigmented epithelial (ARPE-19) cells. AgNPs (0.1-30 µg/ml) were applied to the cells seeded in a 384-well format, with silver nitrate acting as an ionization control. The in vitro sedimentation, diffusion, and dosimetry (ISDD) model was used to estimate the cellular delivered dose. After 24 hrs of treatment, cells were live-labeled with MitoTracker (mitochondria), fixed, permeabilized and labeled with Hoechst-33342 (nuclei), SYTO14 (nucleoli) and fluorescent conjugates of concanavalin A (ER), phalloidin (actin cytoskeleton), and wheat germ agglutinin (Golgi/plasma membrane). A multiplexed cell viability and apoptosis assay was run in parallel. Cells were imaged using an Opera Phenix High Content Screening System and profiled using Harmony High Content Analysis software. Approximately 1700 morphological features were measured per cell and summarized to the well level for analysis. The ISDD model predicted that the fraction of AgNP deposited on cells increased with particle size and differed based on coating (branched polyethyleneimine (BPEI) > citrate > Polyvinylpyrrolidone (PVP)). Phenotypic profiling showed that all AgNP types affected the morphology of each organelle in a concentration-dependent manner, with many effects observed below the threshold for cytotoxicity. The pattern of changes in cell morphology differed across capping agents and silver nitrate. For example, the effect of citrate on mitochondrial texture was opposite that of other AgNP coatings. 60 nm PVP had fewer effects on cell morphology than other coatings, yet showed apoptosis at an estimated delivered dose as low as 1.45 µg/ml. In summary, high content imaging assessed the cellular toxicity of AgNPs, and identified signature morphology patterns that differentiated between three common AgNP coatings. Further, this screening method may inform subsequent assay selection by highlighting the intracellular regions effected by AgNPs of interest. *This abstract does not necessarily reflect USEPA policy.*

**MP248 Cross-species compartmental modeling of selenium in fishes exposed to selenomethionine via ingestion**

*D. Green, University of Saskatchewan / Toxicology Centre; D.M. Janz, University of Saskatchewan / Veterinary Biomedical Sciences; K. Liber, University of Saskatchewan / Toxicology Centre; M. Brinkmann, M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre*

Selenium (Se) is a trace element and essential nutrient for almost all forms of life. However, it is also a common component and/or contaminant in industrial and agricultural activities and effluents, and can be toxic when encountered in excess. Where aquatic environments are inundated with Se the biota show increased Se concentrations, presumably in the bioaccumulative form of selenomethionine (SeMet), a naturally occurring organic methionine analogue. Many organisms that ingest SeMet show increased risk of toxicity commensurate with exposure, and oviparous animals show increased maternal transfer of Se to their eggs, which can cause significant teratogenicity of exposed embryos. Though the primary mechanism identified for SeMet toxicity is the redox cycling of its metabolite methylselenol, not all fish species exposed to SeMet manifest symptoms of oxidative stress, suggesting alternate toxicity pathways may exist. The non-specific substitution of SeMet for methionine presents a vast number of ways in which SeMet might disrupt animal physiology, including an enhanced propensity of protein oxidation, disruption of methylation cycles, and alternative regulation of SeMet and methionine molecules and metabolites, including homocysteine, which could have broad ramifications for numerous animal systems. Cross-species systemic partitioning models can therefore be employed to characterize the relative organ sensitivities within and across species, which can then be compared with species specific SeMet pathologies to help identify the broader suite of mechanistic pathways affected by SeMet. This information can then be used to direct targeted explant and/or in vitro studies, which will enhance our mechanistic understanding of SeMet toxicity, and lead to better Se risk assessment while reducing expenditure of time, money, and animal life.

**MP249 Future Water Quality Challenges to Aquaculture**

*S. Siddiqui, J.L. Conkle, Texas A&M University, Corpus Christi / Physical and Environmental Sciencees*

Concerns about water quantity and quality are increasing due to climate change and population growth. Climate change is driving changes in evapotranspiration and precipitation patterns. This is exacerbated as population growth, particularly in arid and semi-arid regions, increases water extraction and consumption. Aquaculture is growing both globally and within the U.S. (worldwide 9.2% $yr^{1}$ 1990-2000 & 6.2% $yr^{1}$ 2000-2012; vs U.S. agriculture 1.86% $yr^{1}$ 1990-2000) (FAO, 2014; Ball et al., 2017). Freshwater aquaculture in the U.S. is largely dependent on surface water (80.78%) and ground water sources (19.32%) (Maupin et al., 2010). Surface water sources are increasingly dominated or dependent on treated wastewater effluent. Wastewater effluent generally contains trace levels of anthropogenic compounds, typically referred as contaminants of emerging concern (CECs), for which our knowledge of their impacts is still evolving. Therefore, the introduction of CECs in aquaculture from surface waters influenced by wastewater effluent is a potential concern for cultured fish health as well as for humans when consuming farmed fish. To improve our understanding of future water resource quality and quantity in relation to the feasibility and safety of aquaculture, wastewater effluent and surface water data was collected, consolidated and analyzed to examine trends in surface water quantity and quality. This data was collected from databases maintained by the United States Geological Survey (USGS) and United States Environmental Protection Agency (USEPA). Next, trends in HUC Wastewater effluent to stream flow dilution was statistically analyzed towards the water quality and fresh water availability in USA, which is projected for next five years using Prophet model in R. The results were then visualized using GIS to explore future water scenarios in the USA.

**MP250 T1000: identification of toxicogenomics gene sets for improved risk assessment of environmental toxicants**

*O. Soufan, McGill University / Institute of Parasitology; J. Ewald, McGill University – Macdonald Campus / Natural Resource Sciences; C. Viau, McGill University – Macdonald Campus; D. Crump, Environment and Climate Change Canada / National Wildlife Research Centre; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre; J. Xia, McGill University; N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences*

BACKGROUND: With thousands of untested exposure chemicals in the environment, selection of a responsive set of genes can facilitate high-throughput screening (HTS). However, while several gene lists were published based on a genome-wide expression profiling, a toxicogenomics signature is not well-addressed. OBJECTIVES: To find a set of globally responsive genes representing a reference signature for efficient HTS of potential effects of toxic chemicals. METHODS: Here we developed a novel machine learning approach to systematically characterize genes that are highly responsive in toxicogenomics studies. Toxicogenomics-1000 (T1000) gene signatures are derived based on in vitro and in vivo experiments from human and rat. RESULTS: A list of 1000 ranked genes (T1000) has been generated as a reference toxicogenomics signature. External evaluations have shown that T1000 achieved a correlation of about 90% of time match apical outcomes versus 24 experimental groups. When compared to baseline gene sets mapped using Limma and L1000 on the Rat Genome 230 2.0 Array, T1000 achieved a relative improvement on the $F_1$Score by 6% and 17%, respectively. The applicability of T1000 was demonstrated in a wide range of toxicological endpoints with 7,142 expression profiles. CONCLUSIONS: T1000 reference gene list represents a highly responsive signature for toxicogenomics studies. The achieved patterns of responses in genes and related pathways shows that T1000 can improve current HTS assays in toxicogenomics studies to facilitate prediction of adverse health outcomes.

## Terrestrial Toxicology, Ecology and Stress Response

### MP252 Assessing seasonal factors influencing parasitic infection in northern bobwhite quail of the Rolling Plains, TX using a mobile laboratory platform

*K. Blanchard, Texas Tech University / Environmental Toxicology; K. Commons, A. Kalyanasundaram, Texas Tech University / Wildlife Toxicology Laboratory; C. Henry, Texas Tech University; M.Z. Brym, R.J. Kendall, Texas Tech University / Wildlife Toxicology Laboratory*

Northern bobwhite quail (*Colinus virginianus*), a popular gamebird, have been declining over recent decades in the Rolling Plains ecoregion of the United States. Previous investigations have revealed a high prevalence of eyeworms (*Oxyspirura petrowi*) and caecal worms (*Aulonocephalus pennula*) in quail from this area. This prevalence has been observed alongside numerous reports of bobwhites flying into objects as well as up to 100% infection in some areas of this ecoregion, prompting a need to better understand host-parasite interaction and other factors that influence infection. In this study, a mobile research laboratory is used to detect and quantify infection levels in bobwhite at three field sites in the Rolling Plains. Due to the life cycle in which these parasites operate, parasite eggs are expelled through the feces, consumed by an insect intermediate host, and subsequently eaten by a bobwhite. To detect the parasite eggs, cloacal swabs and feces from bobwhites are collected at each field site, then DNA is extracted and run using highly specific and accurate quantitative PCR (qPCR) to non-lethally assess infection and release unharmed the sampled quail. This data, coupled with data from previous years, provides valuable insight in understanding potential climactic factors that can impact parasite activity. Additionally, this research can identify the best timing of future anthelmintic treatment application in congruence with nematode diapause, a phenomenon that is suggested to hinder the effectiveness of treatment. These methods can also be integrated into current investigations of the role of parasites in bobwhite stress responses and possibly enhanced susceptibility to chemical exposure. Nevertheless, with the current use of a mobile research laboratory and an understanding of influential climactic factors, future effective treatment methods can be implemented to contribute to successful mitigation of parasitic infection and attempt to stabilize bobwhite populations in the Rolling Plains.

### MP253 Assessment of pesticide impacts on soil microbial viability using fluorescence, carbon dioxide, and nitrate assays

*M.L. Coimbra, Middle Tennessee State University / Forensic Science; Z. Forbes, Middle Tennessee State University / Department of Biology; E. Manovic, K. Summers, I. Zecevic, J. DiVincenzo, Middle Tennessee State University / Chemistry*

Over 5 billion pounds of pesticides are used worldwide each year. Assessment of their impacts on soil microbes is essential as soil microbial functions such as $CO_2$ production and nitrogen cycling are critical to crop production and soil sustainability. Microbial viability in the presence of some common pesticides was assessed using fluorescence spectroscopy with nucleic acid stains, quantification of nitrate using ion chromatography, and titration of $CO_2$ evolved in respiration chambers. Glyphosate, imidacloprid, and 2,4-dichlorophenoxyacetic acid all showed a reduction in the ratio of live/dead soil bacteria when compared to untreated liquid soil cultures, with as much as 58% (imidacloprid) of the bacteria classified as nonviable. Monitoring of nitrate levels produced in nitrifying cultures showed significant reduction in nitrate production in the presence of either malathion or 2,4-D with an 8-fold reduction (from 242 to 28 mg/L) for malathion used at recommended dosages. Glyphosate spiked soil column studies showed anywhere from 28-55% (95% confidence) reduction in nitrate production but returned to normal nitrate production 3 weeks after application. $CO_2$ evolution from 5-day liquid soil cultures was reduced by as much as 99% (95% confidence) in the presence of malathion where 2,4-D treated cultures were much more inconsistent in response and showed no statistically significant effect. Continued assessment of the effects of pesticides on soil microbes is essential in order to develop prudent practices for their uses and to minimize impacts on soil microbial health.

### MP254 Assessment of Phytotoxicity of Ammonia on Radish (*Raphanus sativus*): Comparative Study on Phytotoxicity According to Chemical Accident Scenarios

*M. Park, S. Hyun, Korea University / Department of Environmental Science and Ecological Engineering*

There are differences in the damage of the terrestrial ecosystem caused by chemical accidents depending on accident chemicals and type of chemical accidents. It is necessary to establish ecotoxicity database of accident chemicals through studies for ecotoxicity evaluation to accurately estimate the damage of the terrestrial ecosystem caused by chemical accidents. The terrestrial ecosystem can be exposed to ammonia, which is regulated as a chemical with a high frequency of accidents by Korea Ministry of Environment (MOE), through two pathways; i) inflow of aqueous ammonium hydroxide ($NH_4OH$) into the soil due to spillage and ii) deposition of gaseous ammonia ($NH_3$) due to explosion. Phytotoxicities of ammonia on radish (*Raphanus sativus*), representative field crop in Korea, according to chemical accident scenarios were assessed and compared. *R. sativus* was grown to 2 ~ 4 true leaf stage in non-contaminated condition according to the OECD guideline 227 and then exposed to aqueous $NH_4OH$ or gaseous $NH_3$. The number of survivors, biomass, chlorophyll content, and visible damages on the leaves were measured after four weeks of cultivation. The toxicity values (LOEC, NOEC, and $EC_{50}$) were calculated using SAS 9.3 software. Relatively sensitive endpoints were selected through comparison of phytotoxicities according to chemical accident scenarios. The results of this study will provide the appropriate ecotoxicity data of ammonia according to the exposure pathway when the terrestrial ecosystem is exposed to ammonia due to chemical accidents. Acknowledgement: This subject is supported by Korea Ministry of Environment(MOE) as "The Chemical Accident Prevention Technology Development Project."(2016001970003)

### MP255 Chronic toxicity of four insecticides to *Apis melifera* larvae reared in vitro

*K. Chon, B. Kim, H. Lee, National Institute of Agricultural Sciences; K. Park, National Institute of Agricultural Sciences / Chemical Safety Division; M. Paik, National Institute of Agricultural Science*

Honey bees can be exposed to pesticides and environmental toxic compounds while foraging in diverse environments. In addition to honey bees, larvae can be exposed to various pesticides from residues contained in pollen, nectar, and wax in the hive. However, at present, side effects and toxicity of pesticides on larvae are poorly investigated. The objective of this study is to assess the chronic toxicity of four insecticides to honey bee larvae using an in vitro rearing method adopted by OECD GD NO.239. Carbaryl, chlorpyrifos, cypermethrin, and diazinon were chosen for this study because they are the most widely used insecticides for agricultural area in Korea and also known to be detected in nectar, pollen, and wax. The $LD_{50}$ values of carbaryl, chlorpyrifos, cypermethrin, and diazinon at D8 were 1.00, 0.07, 0.17, and 0.43 ug/larva, respectively; at D15 were 1.13, 0.06 0.17, and 0.40 ug/larva, respectively; and at D22 were 0.88, 0.05, 0.13, and 0.35 ug/larva, respectively. The toxicity of the four insecticides to honey bee larvae from most to least toxic was chlorpyrifos > cypermethrin > diazinon > carbaryl. Various mortality symptoms at sublethal concentration like melanizing, failed molt, failed adult molt, and deformed adults were also observed and recorded.

**MP256 Comparing the effects of nanoparticles ZnO, CuO, and TiO2 nanoparticles on reproductive function and gene expression in *Caenorhabditis elegans***

*T. Thornburg, X. Pan, East Carolina University / Biology*

The use of metal oxide nanoparticle in forms of Zinc, Titanium and Copper oxides has been increased nowadays in various consumer products. However, the toxicity information regarding exposure to these nanoparticles are still limited. This study focuses on investigating their impacts on reproductive functions and comparing of toxicity between different nanoparticles with different metal components. The model organism *Caenorhabditis elegans* (*C. elegans*) was used and the following experiments are performed: 1) Characterize effects of exposure to a range of environmentally relevant concentrations of ZnO, CuO, $TiO_2$ on reproductive function. Reproductive defects include alterations in brood size, abnormalities in spermatogenesis, oogenesis, embryogenesis, and abnormality in offspring development and behaviors. And 2) Evaluate effects of exposure to different metal oxide nanoparticles on gene expressions by quantitative real-time PCR. Our preliminary observations using florescence microscope following DAPI staining have identified the changes in gonadal morphology, chromosome integrity, and mitosis and meiosis progression following exposures. The gene expression analysis are ongoing. Changes in worm locomotion behaviors following exposure have also been characterized. This study using the *C. elegans* model will guide validation studies in vertebrate animals.

**MP257 Effects of PCB exposure on thyroid hormone levels in serum of dogs and cats**

*K. Takaguchi, H. Nishikawa, Ehime University / Center for Marine Environmental Studies; H. Mizukawa, Hokkaido University / Graduate School of Veterinary Medicine; R. Tanoue, Ehime University / Center for Marine Environmental Studies; N. Yokoyama, O. Ichii, M. Takiguchi, S.M. Nakayama, Y. Ikenaka, Hokkaido University / Graduate School of Veterinary Medicine; T. Kunisue, Ehime University / Center for Marine Environmental Studies; M. Ishizuka, Hokkaido University / Graduate School of Veterinary Medicine; S. Tanabe, H. Iwata, K. Nomiyama, Ehime University / Center for Marine Environmental Studies*

Thyroid hormones (THs) such as 3,3’,5-triiodo-L-thyronine ($T_3$) and L-thyroxine ($T_4$) are essential for the regulation of growth and development. Recent studies reported that polychlorinated biphenyls (PCBs) and their hydroxylated metabolites (OH-PCBs) affect the TH homeostasis. In our previous studies, concentrations of PCBs and OH-PCBs in pet cat serum showed significant negative correlation with THs. However, there are no in vivo evidences on the adverse effects of PCB exposure on thyroid hormone homeostasis of pet animals. Thus, the present study aimed at investigating the effects of PCB exposure on TH homeostasis in dogs and cats by measuring serum TH levels following a single dose of 12 PCB congeners (0.5 mg/kg of each congeners: CB18, 28, 70, 77, 99, 101, 118, 138, 153, 180, 187 and 202) and by examining the relationships with levels of PCBs and OH-PCBs. Concentrations of PCBs and OH-PCBs in dog serum were higher than those in cat serum after 24 hours exposure to the same dose of PCBs. In dog, free T4 level increased with PCB exposure and was positively correlated with the levels of T4-like OH-PCBs including 4-OH-CB107 and 4-OH-CB202. This was probably caused by competitive binding between T4 and T4-like OH-PCBs to TH transport proteins. Additionally, total T4 and total T3 levels in PCB-exposed dogs lower than in the control group and were negatively correlated with PCB concentrations. It was reported that PCB exposure induced the decrease of total T4 in serum due to induction of UDP-glucuronosyl transferase (UGT) and accumulation of T4 in liver. This result implies that PCB exposure enhanced TH excretion in dog by increasing TH uptake and UGT activity in the liver. In contrast, TH levels in cat sera did not change with PCBs exposure. This result can be explained by the lower levels of PCBs and T4-like OH-PCBs compared with dogs and very low activity of UGTs in cats.

**MP258 Gallic acid protects against bisphenol A-induced alterations in the cardio-renal system of Wistar rats through the antioxidant defense mechanism**

*O.E. Ola-Davies, University of Ibadan, Nigeria / Veterinary Physiology and Biochemistry; S.G. Olukole, University of Ibadan, Nigeria / Department of Veterinary Anatomy*

Bisphenol A (BPA) is a small molecular weight endocrine disrupting chemical (EDC) that is used in the production of plastics with deleterious effects on various body systems while gallic acid (GA) is a known antioxidant capable of ameliorating EDC-induced perturbations. In this study, adult male rats (180 ± 5g) were divided into four groups of eight rats each: Group A (Control rats): 0.2 ml of corn oil; Group B (GA-treated rats): 20 mg/kg/day GA (dissolved in distilled water); Group C (BPA-treated rats): 10 mg/kg/day BPA suspended in 0.2 ml corn oil; Group D (BPA+GA-treated rats): BPA (10 mg/kg/day) with a concomitant GA (20 mg/kg/day). All treatments were orally administered for 14 days. BPA induced significant decrease in systolic, diastolic and mean arterial blood pressure while causing a significant increase in heart rate in the rats. It significantly raised both renal and cardiac reactive oxygen species and depleted the antioxidant system. There were also significant increases in serum myeloperoxidase, nitric oxide, urea and creatinine in the BPA-treated rats. Lesions of the heart and kidney including inflammation, vascular congestion and erosion of epithelial cells were also observed in the BPA-treated rats. However, the concomitant treated with GA ameliorated all the BPA-induced alterations of the cardio-renal system. Hence, low dose of GA serves a protective function against BPA-induced toxicity of the heart and kidney.

**MP259 Impact of Seasonal Temperature Variation on Pesticide Fate and Metabolism in Urban Landscapes**

*A.E. Gonzalez Vazquez, Molecular and Environmental Toxicology Center; M. Millican, University of Wisconsin, Madison / Department of Plant Pathology; P. Koch, University of Wisconsin, Madison / Molecular and Environmental Toxicology Center*

The United States contains 50 million acres of managed turfgrass. In order to maintain this turfgrass acreage, approximately 30 million kilograms of pesticides are applied to urban landscapes, representing more than 20% of the total pesticide usage in the U.S. The herbicide, 2,4-dichlorophenoxyacetic acid (2,4-D) is among the most commonly used pesticides for turfgrass management in urban landscapes. Although the fate and breakdown of 2,4-D has been well documented, assessments of its transformation products (TPs) under varying environments have not yet been clearly elucidated. Biotic mechanisms are considered to be the primary force of pesticide degradation within soil ecosystems and can be largely influenced by a broad range of environmental factors. Specifically, temperature variations are a central environmental factor that directly influences the soil microbiome structure and activity which may indirectly alter pesticide degradation networks and in the formation of multiple TPs with varying toxicological effects. Within this context, there is limited knowledge regarding pesticide-microbe interactions in urban soils and their metabolic pathways under the varying environmental conditions that 2,4-D is typically applied. In this study, we investigated the formation of 2,4-D metabolites under seasonal temperature fluctuations and evaluated how these variations influence microbial-pesticide interactions. Growth chamber and field studies were performed on turfgrass samples to assess 2,4-D’s fate and movement under both natural and controlled environment conditions. Pesticide extractions were performed using a modified multiresidue Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) solid-phase extraction method. Electrospray ionization Liquid Chromatography/Mass Spectrometry analytical protocols were also developed for the detection of 2,4-D and its respective TPs in turfgrass soil samples. TP formation in response to seasonal turfgrass-associated microbial community changes was also assessed through microbiome analysis and targeting the 2,4-D degrading gene, TfdA, commonly found in soil bacteria.

### MP260 In-Vitro Evaluation of Potential Hepatotoxicity Induced By Detergent-Processed Cassava Product

*I.O. Awotunde, O.T. Aladesanmi, Obafemi Awolowo University / Institute of Ecology and Environmental Studies; R.O. Akomolafe, Obafemi Awolowo University, Ile-Ife / Department of Physiological Sciences*

Toxic effects of cassava-based products on humans have been established. The recent use of detergent in processing cassava into food products such as *fufu* (a local delicacy Nigeria), may exacerbate its toxic effect. This study determined the hepatotoxicological effect of detergent-processed *fufu* on Wistar rat. The liver is a heterogeneous organ which is involved in detoxification of xenobiotics and is highly susceptible to injury from these substances. With the increase in chronic diseases among the Nigeria growing population, there is need to look beyond pathogenic and infectious diseases and focus on public health nutrition. Rat models were used in assessing the degree of damage caused on the haematological and hepatological parameters. Graded concentrations (7.5mg/L, 15mg/L and 22.5mg/L) of detergent was used in fermenting cassava for making the *fufu* which was used in the study. Wistar rats were given 7 feeding treatments (TRT): TRT I – positive control (commercial rat feeds only); TRT II – positive control (*fufu* only); TRT III – negative control (detergent only), TRT IV – designated control (*Fufu* bought from the open market), TRT V – VII (*fufu* plus graded concentrations of detergent). Liver marker enzymes were assayed in the plasma and liver homogenate, blood parameters were also analysed after four weeks of treatment.. Levels of marker enzymes such as Alanine Aminotransferase (ALT), Aspartate Aminotransferase (AST), and Alkaline phosphatase (ALP) were increased significantly across all the detergent treatment groups and TRT II and IV, while plasma ALP only increased in TRT III . No significant difference was observed in the liver homogenate except in AST which showed increase across all treatment groups except group VIII. There was no significant difference in the blood parameters across all groups. The present observations suggested that consumption of detergent-processed *fufu* poses risk to the liver while the blood parameters remain unaffected

### MP261 Individual and Combined Treatment Effects of Pesticides, Fertilizers, and Salt on Larval Amphibian (*Lithobates sphenocephala*) Growth and Stress Levels

*R. Adelizzi, J. Portmann, R. Van Meter, Washington College / Environmental Science and Studies Department*

Human activities have introduced a variety of chemicals, including pesticides, fertilizers, and salt, into the environment which have had deleterious effects on the organisms inhabiting these areas. Amphibians are especially susceptible to absorption of chemical pollutants. To determine the possible combined effects of these chemicals on amphibian development and stress levels, Southern leopard frog (*Lithobates sphenocephala*) larvae were exposed to one of eight individual or combined treatments of atrazine, ammonium nitrate fertilizer, and sodium chloride salt. Stress levels, indicated by release of the stress hormone corticosterone, were measured pre-metamorphosis at week 8 of development and again at 24 hours post-metamorphosis. Water hormone samples were processed using ELISA kits from Cayman Chemical to analyze corticosterone levels. Changes in tadpole growth were determined by surface area measurements taken from biweekly photographs analyzed with IMAGEJ software. The combined chemical treatment of atrazine, salt, and fertilizer had a significant interactive effect of increasing stress levels prior to metamorphosis ($p=0.003$), but this effect was no longer apparent 24-hours post-metamorphosis ($p>0.05$). By the end of larval development, tadpoles exposed to nitrogen had significantly larger surface area ($p=0.035$). Tadpoles exposed to atrazine had significantly lower changes in growth throughout larval development ($p\leq 0.001$), however, the frogs in the atrazine treatment metamorphosed faster ($p=0.002$). As amphibians are exposed to multiple chemicals simultaneously in the environment, assessing the effects of a combination of contaminants is necessary to improve application strategies and ecosystem health.

### MP262 Investigating effects of sodium benzoate on the *Caenorhabditis elegans* model

*L. Lewis, East Carolina University / Biology*

Clinical observation has proposed the linkage between the occurrence of obesity and slow weight loss with daily exposure to common food additives such as benzoic acid. However, well-controlled laboratory experiments on this topic have been lacking; the dose-response relationship of benzoic acid and obesity occurrence and/or slow weight loss has not been established; the potential mechanism of such linkage has not been explored. This is an important point because the EPA does not have a current limit on Sodium Benzoate, and the FDA limit has not been updated in over two decades. The insulin-signaling and fatty acid synthesis pathways in the model organism *Caenorhabditis elegans* (*C. elegans*) are highly conserved with higher organism including humans and thereby has been widely utilized to study obesity and aging related mechanisms. Scientific literature links the insulin pathway of *C. elegans* to growth, development, longevity, behavior, and metabolism in the organism (Murphy 2013). *C. elegans* is also a perfect model for exploring the genetics of fat storage (McKay 2003). Thereby, I plan to use *C. elegans* as a model organism to study the effects of benzoic acid exposure on fat storage and on the gene expression of major players in insulin signaling pathway. I hypothesize that long-term exposure to benzoic acid will lead to altered fat storage, and gene expressions in the insulin-signaling and fatty acid synthesis pathways. To test this hypothesis *C. elegans* will be exposed to different concentrations of benzoic acid, and effects will be observed over a long period of their life span. The fat storage of the organism will be monitored using histological staining and microscopic observation and then quantified using imaging software. Genes in the insulin-signaling pathway will be selected and their expression profile will be tested. Once benzoic-acid response genes are identified, mutant strains will be used to test their sensitivity to benzoic acid exposure and further reveal the gene functions in response to benzoic acid exposure. Preliminary data suggest that sodium benzoate has a dose dependent effect on the growth of *C. elegans*. The cause of this growth issue will be explored in further research.

### MP263 Parasite Burdens in Northern Bobwhite Quail from the Rolling Plains Ecoregion of Texas and Potential Interactions with Agricultural Pesticides

*C. Henry, Texas Tech University; A. Kalyanasundaram, M.Z. Brym, Texas Tech University / Wildlife Toxicology Laboratory; K. Blanchard, Texas Tech University / Environmental Toxicology; R.J. Kendall, Texas Tech University / Wildlife Toxicology Laboratory*

A concern that has been increasing in recent years is the impact of parasites in wildlife and how they interact with natural and anthropogenic stressors. Recently, it has been suspected that *Aulonocephalus pennula* and *Oxyspirura petrowi* are playing a role in the decline of the Northern bobwhite quail (*Colinus virginianus*), a popular and economically important gamebird in the Rolling Plains ecoregion of Texas. From January 2017 to March 2018, a total of 154 bobwhite were assessed for the presence of parasites. During this time, we documented some of the highest parasite loads of *A. pennula* and *O. petrowi* recorded in quail in over six years of continuous monitoring with concurrent population drops. This finding was concerning as increased parasite burdens have the potential to suppress the immune system and may explain the increased prevalence of even a third parasite, *Physaloptera* sp., in our samples. The cause for these increased infections remains to be determined and the mechanism for this increase requires further investigation. However, high parasite burdens have also been associated with increased levels of contaminants within a host. The chance of bobwhites being exposed to a contaminant is likely in the Rolling Plains as this region is one of the major producers of cotton in Texas, and cotton utilizes agricultural pesticides, such as neonicotinoids, and may expose bobwhites. The potential interactions of contaminants in the Northern bobwhite quail, such as agricultural pesticides, and parasites in bobwhite will be discussed, particularly in light of the increased prevalence of parasites in this region.

**MP264 Pilot study on the toxicological assessment of organohalogen compounds in pet cat (*Felis catus*) serum using metabolomics approach**

*K. Nomiyama, Ehime University / Center for Marine Environmental Studies; A. Eguchi, Chiba University / Center for Preventive Medical Sciences; H. Mizukawa, M. Takiguchi, S.M. Nakayama, Y. Ikenaka, M. Ishizuka, Hokkaido University / Graduate School of Veterinary Medicine; S. Tanabe, Ehime University / Center for Marine Environmental Studies*

Domestic pets such as dogs and cats share living environments with humans. Therefore, they are exposed to various contaminants, including PCBs and PBDEs in their immediate surroundings, which raise concerns about health risks. Recent studies have reported elevated PBDE levels in the sera of cats. Metabolome analyses performed in toxicological studies provide information about the biological systems and toxicological pathways. The present study determined the levels and accumulation patterns of PCBs, PBDEs, and their metabolites (OH-PCBs and OH-PBDEs) in the blood of pet cats (male= 8, female = 8)collected from a veterinary hospital in Japan. Furthermore, in order to assess the effects of contaminants in pet cats, we also examined relationships between the levels of organohalogen compounds and serum Metabolome levels analyzed using LC-MS/MS. Median concentrations of PBDE (wet weight) in the cat serum (630 pg $g^{-1}$) were higher than that of PCBs (290 pg g−1). Especially, deca-BDE was the predominant homologue, accounting for 60% of total PBDEs concentrations. In the PCB congeners, CB153, 138, 180 and 118 were the predominant homologues. We analyzed polar metabolomics profiling using LC-MS/MS that covers major metabolic pathways. The OPLS analyses found 13 metabolomes (8 increases and 5 decreases) were significantly associated with PCBs concentrations, and 17 metabolomes (15 increases and 2 decreases s) were significantly associated with PBDEs concentrations. Enrichment analysis suggested that PCBs concentrations in the cat serum were associated with the glutathione metabolism, glycerolipid metabolism, pentose phosphate pathway, phenylalanine, tyrosine and tryptophan biosynthesis. In addition, PBDEs concentrations were suggested to be associated with the alanine, aspartate and glutamate metabolism, and pyrimidine metabolism. The activations of pentose phosphate pathway and glycolysis associated with the exposure of these PCBs and PBDEs may be related to the activation of drug metabolizing enzymes (cytochrome P450). Inhibition of GSH and GSSG was observed for PCBs exposure level. Inhibition of GSH and GSSG are known to be sensitive markers for oxidative stress. Therefore, these results was suggested that oxidative stress production accompanying the induction of CYPs.

**MP265 Small-scale spatial variation of methylmercury concentrations in sediments and invertebrates from intertidal wetlands**

*S. De La Cruz, L. Hall, I. Woo, USGS; M. Marvin-DiPasquale, USGS / Water Mission Area; D.P. Krabbenhoft, J. Takekawa, USGS*

Periodic wetting and drying in tidal wetlands re-oxidizes the sulfur and iron in sediments that act as electron acceptors for sulfate- and iron-reducing bacteria known to facilitate the conversion of inorganic mercury (Hg) to methylmercury (MeHg). Wetting and drying frequency and associated sediment re-oxidation is a function of wetland elevation and hydrology. Therefore, small-scale spatial differences in MeHg production can occur in less saturated wetland habitats like channel edges compared to marsh interior habitats that experience more frequent wetting and drying. We compared seven measures of sediment biogeochemistry, including sediment MeHg concentrations, between channel edge and interior habitats in three tidal wetlands along the Petaluma River in San Francisco Bay, CA. We also assessed MeHg concentrations of invertebrates (Amphipoda, Gastropoda, and Arachnida) collected near sediment sampling locations. Sediment MeHg concentrations were significantly greater in interior habitats than along channel edges ($p < 0.001$), and the concentration of inorganic reactive mercury (RHg) contributed significantly to a linear discriminant function, indicating that the RHg pool was more depleted in interior habitats than at the channel edge ($p < 0.001$). We did not detect significant effects of either sediment MeHg (p = 0.95) or percent MeHg (p = 0.96) on invertebrate MeHg concentrations. We also did not find significant differences in invertebrate MeHg concentrations between habitats ($p = 0.39$), suggesting that invertebrate MeHg was not directly associated with surface sediment MeHg concentrations. These findings may have resulted from spatial or temporal mismatches in sediment and invertebrate sampling approaches. Scrapers and detritivores like Gastropoda and Amphipoda forage in the top few millimeters of sediment, where they may be exposed to different MeHg concentrations than those measured in our 2 cm sediment samples. Last, invertebrate uptake of MeHg from sediments is not instantaneous and assimilation rates are unknown for the invertebrates in our study. Thus, temporal lags could have prevented us from detecting a relationship between MeHg concentrations in sediment and invertebrates. Since hydrological patterns can drive wetland MeHg production at small spatial scales, future studies aimed at understanding spatial variation in sediment MeHg and its uptake into food webs should consider the spatial and temporal concordance of their sampling design.

**MP266 Sublethal Effects of Chronic Exposure to CdO or PbO Nanoparticles or Their Binary Mixture on the Honey Bee (*Apis millefera* L.)**

*Y.A. Alnaggar, University of California Riverside / Department of Zoology; K. Dabour, Tanta University / Zoology Department; S. Masry, City of Scientific Research and Technological Application / Department of Plant Protection and Molecular Diagnosis / Arid Lands Cultivation Research Institute; A. Sadek, Cairo University / National Institute of Laser Enhanced Sciences (NILES); E. Naiem, Tanta University / Zoology Department, Faculty of Science; J. Giesy, University of Saskatchewan / Department of Veterinary and Biomedical Sciences and Toxicology Centre*

Cadmium and lead-based nanotechnologies are increasingly used in agricultural, industrial and biological processes; however, potential adverse effects of nanomaterials on honey bees had not been assessed. In this study, effects of exposures to sublethal concentrations of PbO and CdO nanoparticles (NPs), either separately or in combination on honey bee (*A. mellifera*) workers were assessed. Honey bee workers were orally exposed for nine days under laboratory conditions to sublethal concentrations (10% of $LC_{50}$) of CdO (0.01 mg $ml^{-1}$) and PbO (0.65 mg $ml^{-1}$) NPs either separately or combined. Effects on survival, feeding rate, activity of acetylcholinesterase (AChE), and expression of stress-related detoxifying enzymes were quantified. Survival and feeding rates decreased particularly in bees fed sugar syrup containing CdO NPs and binary mixtures of NPs of both metal oxides. Expressions of genes involved in detoxification of xenobiotics were affected by various combinations. Expression of catalase was 13.6-fold greater than control in bees consumed sugar syrup diet containing binary mixture of sub-lethal concentrations of both CdO and PbO NPs. AChE activity in honey bee heads inhibited by 3.8-, 3.0- and 2.8-fold relative to control, respectively in response to exposure to Cd or / and Pb oxides NPs compared to controls, which indicates potential neurotoxic effects of these NPs on honey bees. CdO NPs exhibited the greater potency on honey bees. Overall, honeybee workers suffered detrimental effects when they were exposed to sublethal concentrations of CdO or/and PbO NPs.

## Birds Under Stress: Impacts of Chemical Exposure and Environmental Changes

### TP001 Mercury concentrations vary within and among body feathers in birds: A critical evaluation and guidelines for feather use in mercury monitoring

*S. Peterson, USGS; J.T. Ackerman, USGS / Western Ecological Research Center; C. Eagles-Smith, USGS / Forest and Rangeland Ecosystem Science Center; M. Herzog, USGS / Western Ecological Research Center*

Feathers are an easily and non-lethally collected tissue that is extensively used to represent mercury (Hg) contamination in birds. Yet, few recommendations exist that provide guidance on how to appropriately design, sample, process, and interpret Hg in feathers. This is important because Hg concentrations can vary substantially within and among individual feathers from the same bird. Thus, it is difficult to interpret feather Hg concentrations and laboratory methods may bias results. We conducted a series of 5 experiments to test Hg variability within and among body feathers (breast, back, head) and used the results to develop a tool to guide future feather sampling designs and processing for Hg analysis. We found that 1) Hg concentrations varied extensively among whole feathers within individual birds from 5 orders (1.4-8 fold different), with a coefficient of variation (CV) 9-68%; 2) to obtain a measured Hg concentration within 10% of a bird's true average feather Hg concentration, 4 or 21 feathers were required when the feather CV was 10% or 20%, respectively; 3) Hg concentrations in the feather vane were 44% higher than the rachis and 111% higher than the calamus, indicating that methodological differences in processing can influence the resulting Hg concentrations; 4) using scissors or scissors + liquid nitrogen to homogenize feathers decreased the variability in Hg concentrations among aliquots relative to whole feathers, but using liquid nitrogen introduced a bias by underestimating a bird's true average feather Hg concentration; and 5) the number of whole breast feathers that could be run per sample boat was related to mean species body mass ($R^2$=0.80; n=70 species) due to the capacity of a sample boat for Hg determination. Our tool can be used to guide the strategic design of studies using feathers to quantify Hg contamination in birds and includes 3 critical components: A) variability of feather Hg concentrations within an individual, B) desired accuracy of the measured Hg concentration, and C) feather size. Our results suggest a general rule that, if the goal is to be within 10% of a bird's true average feather Hg concentration by running only 1 sample boat, Hg variability among feathers must be low (CV=10%) and the bird can be larger (≤251g) because only 4 whole feathers need to fit in 1 boat, whereas when Hg variability among feathers is higher (CV=20%) the bird must be smaller (≤16g) because more whole feathers (≥21) need to fit into 1 boat.

### TP002 Comparison of metal exposure and egg characteristics in great tits inhabiting four metal-polluted environments in Europe

*S. Espin, University of Murcia / Health Sciences Department / IMIB Arrixca UM / Faculty of Veternary; P. Sánchez Virosta, University of Turku / Biology; E. Belskii, Institute of Plant and Animal Ecology / Ural Branch / Russian Academy of Sciences; R.A. Costa, Universidade de Aveiro; M. Eens, University of Antwerp / Department of Biology; R. Hargitai, J. Török, Eötvös Loránd University; S. Ruuskanen, University of Turku / Department of Animal Ecology; T. Eeva, University of Turku / Department of Biology*

Metal-polluted environments represent an important challenge for passerines and may affect the maternal investment into egg quality. Toxic metals may impair the eggshell structure as they can alter Ca absorption and the homeostasis and function of Ca. Great tits (*Parus major*) lay white eggs speckled with brown protoporphyrin pigment spots. Toxic metals may also affect this eggshell spotting pattern by depressing the heme synthesis and inducing protoporphyrin accumulation in blood, which may increase its deposition on eggshells in polluted areas. Our aim is to assess the effect of metal exposure on early-stage reproduction in free-living great tits inhabiting different metal-polluted environments in Europe. For this purpose, we carried out an extensive sampling in 2016 to collect eggs and nestling feces for assessing metal exposure in great tits breeding in industrial/urban sites and control environments in Belgium, Finland, Hungary and Portugal. We evaluate different egg characteristics that can be sensitive to metal effects such as eggshell thickness and pigmentation pattern. Generally, nestlings in the industrial/urban environments showed higher metal concentrations in feces, except for Portugal. Nestlings in Belgium were exposed to the highest metal levels. The eggshell index was slightly lower in the polluted site compared to the control site in Belgium while the opposite trend was found in Hungary, maybe due to the better Ca availability in the Hungarian polluted site. Although birds in industrial/urban environments were exposed to higher metal levels, the current pollution load is not affecting the eggshell quality. Eggs in the polluted environments showed higher spot intensity in Belgium, Hungary and Portugal, whereas neither effects on spot distribution nor size were found. Ca levels and toxic metals showed an interactive effect on spot intensity, suggesting that eggshell protoporphyrin-spotting intensity may be affected depending on the balance between metal pollution and Ca availability. ### TP003 Reviewing and Using Current Toxicity Literature to Derive an Aquatic-Dependent Avian Tissue Residue Value (TRV) for Mercury

*A. Jarvis, C. Bergeron, M. Elias, B. Schnitker, K. Gallagher, USEPA / Office of Water*

Mercury contamination of aquatic ecosystems is widespread and bioaccumulation and biomagnification of methylmercury occurs through the aquatic food web. Aquatic-dependent bird species appear to be particularly sensitive to mercury exposure, experiencing effects such as reproductive impairments at environmentally relevant concentrations (Burgess and Meyer 2008; Brasso and Cristol 2008). Both the Great Lakes Initiative (GLI 1993) and Mercury Study Report to Congress (MSRC 1997) included derivations of an avian Tissue Residue Value (TRV). During the development of both the GLI and the MSRC, the results of several mallard studies (Heinz 1974, 1976a, 1976b, and 1979) were determined to be the most appropriate toxicity endpoints for the derivation of an avian TRV. These mallard studies demonstrated that exposure to dietary methylmercury reduced reproductive success at 0.5 ppm methylmercury (Heinz 1979). Both the GLI and MSRC utilized this toxicity endpoint as a lowest adverse effect level (LOAEL), which was then adjusted by an uncertainty factor of 6 (GLI 1993) or 3 (MSRC 1997) to derive TRVs of 13 µg/kg and 26 µg/kg, respectively. In the 20 years since the development of the GLI and MSRC, mercury lab and field-based toxicity studies focused on a wide diversity of bird species have provided additional information into the potential effects of mercury and the relative sensitivity of birds. The current work includes review of the latest scientific literature on the effects of mercury on aquatic-dependent birds and application of new data to develop updated toxicity values for some aquatic-dependent bird species.

### TP004 Role of oxidative status on growth and fledging success in great tit nestlings: A calcium supplementation experiment in a metal-polluted area

*P. Sánchez Virosta, University of Turku / Biology; S. Espín, University of Murcia / Sociosanitary Sciences; S.R. Ruiz, J. Stauffer, M. Kanerva, University of Turku / Department of Biology; A. García-Fernández, University of Murcia / Health Sciences Department / IMIB-Arrixaca / Veterinary Faculty; T. Eeva, University of Turku / Department of Biology*

The increased metabolic activity associated with rapid growth may cause oxidative stress that may affect physiological and life-history traits such as nestling size, growth or fledging success. Thus, nestling development is a demanding period that may be even more challenging when birds inhabit environments suffering from metal pollution and reduced food quality and quantity. Our aim is to explore the effects of antioxidant molecules and oxidative damage biomarkers on nestling size, growth and fledging success taking into account the metal exposure in great tit (*Parus major*) nestlings. During a Ca-manipulation experiment, great tits were supplemented with Ca or not supplemented (Control group) in a metal-polluted and a control area in SW Finland. We measured oxidative stress biomarkers (GSH, GSH:GSSG ratio, GPx, GST, CAT, SOD, lipid peroxidation -TBARS- and protein carbonylation) in red blood cells. Our results showed that smaller nestlings showed higher TBARS levels, suggesting that nestlings suffering poorer condition have increased lipid peroxidation. However, the lack of differences in TBARS levels between zones shows that metal exposure seems to be low to directly produce oxidative damage to lipids. In addition, a higher growth rate was associated with higher TBARS levels in erythrocytes, showing that nestlings growing faster may have a weaker capacity to face oxidative damage. A higher growth rate was also associated with enhanced CAT activity and tGSH levels (in the polluted area), probably reflecting an up-regulation of those antioxidant molecules in response to the increased oxidative challenge in growing nestlings, particularly in those exposed to low doses of metals. Similarly, the fledging success increased with increasing CAT activity in the polluted area, which may reflect the necessity of the organism to enhance this enzyme to improve its probability to fledge in response to the increased oxidative stress in a situation of metal exposure and lower quality and quantity of food. Finally, increased number of fledglings was associated with decreased SOD activity, which could reflect higher oxidative stress in nestlings from larger broods due to sibling competition. Our study shows that antioxidant molecules and oxidative damage were related to nestling development, and the oxidative status, conditioned by metal pollution, may have consequences on growth and fledging success. *Acknowledgements*: Academy of Finland, UTUGS and *Fundación Séneca*.

**TP005 Occurrence of legacy pesticides, current use pesticides, and flame retardants in conservation areas**

*S. Wang, Indiana University, Bloomington / School of Public and Environmental Affairs; K. Romanak, Indiana University / School of Public Environmental Affairs; T. Steiniche, J. Eric, M. Wasserman, Indiana University / Department of Anthropology; M. Venier, Indiana University / SPEA*

The prevalence and environmental adverse effects of persistent organic pollutants (POPs), likepolybrominated diphenyl ethers (PBDEs) and legacy pesticides, are a well-known problem. Since environmental threats such as global environmental change and pollution occur across borders and boundaries, protected areas are vulnerable despite their conservation status. To improve current conservation practices, a better understanding of how these threats move into protected areas is needed. Therefore, we examined the occurrence of legacy pesticides, current use pesticides (CUPs), and flame retardants in forests across Costa Rica and Uganda. We aimed to identify how regional differences and protected status influenced potential exposure to organic pollutants in protected areas. Air samples were collected using passive samplers with polyurethane foam (PUF) disks. Passive air samplers were deployed for ~3 months in Kibale, Uganda, and two biological field stations in Costa Rica. In Costa Rica, we selected La Selva Biological Station, which is surrounded by agricultural land used for bananas and pineapple and Las Cruces Biological Station, which is surrounded primarily by small-scale farming including coffee and cattle. Samples were analyzed for legacy pesticides, CUPs, and flame retardants, including PBDEs and organophosphate esters (OPEs) using gas chromatography mass spectrometry. Both in Costa Rica and Uganda, congeners BDE47 and BDE99 were the most abundant among PBDEs, TNBP, TCEP and TCIPP among OPEs, and chlorpyrifos among CUPs. The most abundant legacy pesticides were endosulfan and chlordane in Costa Rica and aldrin in Uganda. The median of legacy pesticides, CUPs, OPEs, and PBDEs at La Selva were 14.3 pg/$m^3$, 41.9 pg/$m^3$, 491 pg/$m^3$, and 3.75 pg/$m^3$, respectively, and 5.38 pg/$m^3$, 843 pg/$m^3$, 764 pg/$m^3$, and 7.35 pg/$m^3$ respectively, at Las Cruces. In Uganda, the median of legacy pesticides, CUPs, OPEs, and PBDEs were 46.5 pg/$m^3$, 6.91 pg/$m^3$, 247 pg/$m^3$, and 1.27 pg/$m^3$, respectively. Las Cruces and Kibale had the lowest levels of CUPs, but this was not the case for legacy pesticides, suggesting that long-term exposure to emerging and legacy pollutants occurs also in protected areas, regardless of protected status.

**TP006 Gulls as Bioindicators of Flame Retardant Emissions from UK Landfill**

*A. Tongue, The University of Birmingham; D. Drage, The University of Birmingham / School of Geography Earth and Environmental Sciences; S.J. Harrad, The University of Birmingham; S.J. Reynolds, The University of Birmingham / School of Biosciences; K.J. Fernie, Environment & Climate Change Canada / Ecotoxicology and Wildlife Health*

Waste streams are important reservoirs of legacy brominated flame retardants (BFRs). Several bird species use landfill as a foraging substrate and can be effective bioindicators of such persistent organic pollutants (POPs). We investigated BFRs and novel BFRs (NBFRs) across a UK landfill species-assemblage of gull taxa (*Larus* spp.) and report concentrations and profiles of polybrominated diphenyl ethers (PBDEs), hexabromocyclododecanes (HBCDD) and NBFRs in eggs of five gull species: black-headed gull *Chroicocephalus ridibundus*, common gull *Larus canus*, great black-backed gull *L. marinus*, European herring gull *L. argentatus* and lesser black-backed gull *L. fuscus*. Eggs were collected in Scotland (UK) from gull colonies located within 3 km of a landfill and those from reference sites. Aliquots (1 gram) of egg samples were spiked with internal standards prior to pressurised liquid extraction combined with an in-cell multi-silica clean-up. Clean extracts were concentrated to near-dryness and reconstituted in toluene containing recovery determination standards. PBDEs and NBFRs were determined via GC-EI/MS. HBCDD was determined by LC-MS-MS. Comparatively high arithmetic mean BFR concentrations in the eggs of great black-backed gulls ($\sum_7$PBDEs: 37.2 ng/g ww; HBCDD: 8.04 ng/g ww) and European herring gulls ($\sum$PBDEs: 34.3 ng/g ww; HBCDD: 4.5 ng/g ww) may be connected to their relatively wide foraging niches and abundance at the landfill study site, respectively. Black-headed gulls ($\sum$PBDEs: 5.71 ng/g ww; HBCDD: 1.24 ng/g ww) and common gulls ($\sum$PBDEs: 14.3 ng/g ww; HBCDD: 2.8 ng/g ww) were not observed foraging on this particular landfill, possibly explaining their relatively lower mean BFR egg burdens. Lesser black-backed gulls, which were observed using the landfill in small numbers, exhibited mean $\sum$PBDEs of 16.5 ng/g ww and mean HBCDD of 1.44 ng/g ww. Among NBFRs, we have detected only DBDPE at concentrations >1 ng/g ww, in five individual eggs of four species, i.e., black-headed gull (42 ng/g ww), common gull (27 ng/g ww), great-black-backed gull (484 ng/g ww) and European herring gull (two eggs: 3.3 and 4.8 ng/g ww). The relatively high concentrations in black-headed and common gulls (species that were not observed on the study landfill) may possibly suggest that landfill is not yet a major source of DBDPE. We believe that the DBDPE concentration reported in the great black-backed gull egg (484 ng/g ww) is the highest reported in wildlife to date.

**TP007 Avian red blood cells exposed to crude oil in vitro have damaged membranes and denatured hemoglobin**

*J.B. Krall, Oklahoma State University / Integrative Biology; C. Goodchild, Oklahoma State University; S.E. DuRant, University of Arkansas*

Population damage assessments of bird populations exposed to oil spills typically include counting the number of bird carcasses and visibly oil-coated birds, but often do not consider sub-lethal effects of ingesting crude oil. Other studies have shown that Heinz bodies (i.e., inclusions of denatured hemoglobin on red blood cell membranes) can be used as an indicator of oxidative damage to erythrocytes in birds exposed to crude oil. However, there is variation among bird species in whether crude oil exposure results in the formation of Heinz bodies and it is unclear whether the absence of Heinz Bodies indicates a lack of damage to erythrocytes.

In this study, we examined hemoglobin denaturation and membrane integrity in a species of bird that does not appear to form Heinz Bodies to discover if crude oil exposure causes oxidative damage to occur, even without the presence of Heinz Bodies. Erythrocytes were collected from zebra finches (*Taeniopygia guttata*) and exposed in vitro to six different concentrations of crude oil prepared as a PBS accommodated fraction (10, 20, 40, 100, 200, 400 ug/mL PAH) for 24 hours. To assess hemoglobin denaturation, we measured methemoglobin and t-parameter (i.e., hemoglobin degradation to hemichromes). We examined membrane integrity by measuring erythrocyte osmotic fragility. We found that exposure to crude oil causes hemoglobin degradation and impairs membrane integrity. Our study suggests that while Heinz Bodies are good indicators for oxidative damage for some bird species, erythrocyte damage can occur even in birds that do not form Heinz Bodies.

**TP008 Estimating Polychlorinated Biphenyl Risks to Birds: Dietary Doses, Egg Concentrations, and Body Weight Scaling**

*L. Brown, P.C. Fuchsman, J.B. Taylor, A.F. Brady, M.H. Henning, Ramboll*

Although dietary dose-based toxicity reference values (TRVs) are typically used in food web models, it is well accepted that for many contaminants, egg concentrations can support more accurate risk estimates for birds. As such, tissue data provide a means to evaluate whether body weight scaling of TRVs for interspecies extrapolation improves the accuracy of risk estimates. We compared risk estimates for the polychlorinated biphenyl (PCB) mixture Aroclor 1254 in two avian species, gray catbird and great blue heron, using three measures of exposure and effect: 1) dietary doses (in milligrams per kilogram body weight per day) compared to dose-based TRVs, 2) dietary doses compared to body weight-normalized dose-based TRVs, and 3) modeled egg concentrations compared to egg-based TRVs. We used the same dietary assumptions and exposure point concentrations in each scenario. Due to variations of the aryl hydrocarbon receptor among species, gray catbirds exhibit high sensitivity to PCBs, and great blue herons are less sensitive. Dose and egg TRVs were developed from the scientific literature for each sensitivity group. Gray catbird TRVs were based on dose-response analyses of chicken toxicity studies, and great blue heron TRVs were based on no-effect exposures in mallards. An alternative egg-based TRV from a black-crowned night-heron study was also evaluated. Dose-based TRVs were normalized by body weight from the TRV species (chicken and mallard) to the wildlife species (catbird and heron) using the $BW^{3/4}$ scaling method employed by USEPA for human health risk assessment purposes. To model risks based on egg TRVs, PCBs in eggs were estimated from PCBs in diet. Paired diet and egg data were identified from the literature, and diet-to-egg bioaccumulation regressions were developed for Passeriformes (applied to catbird) and Pelecaniformes (applied to heron). The resulting risk estimates show better agreement between egg-based risks and dose-based risks determined using body weight scaling, with greater divergence when body weight scaling was not used. This analysis is part of a broader effort to encourage scientific consensus to move toward reinstating body weight scaling as an acceptable tool for wildlife TRV extrapolation. Meanwhile, the egg modeling approach provides a less controversial tool to achieve greater realism in avian risk estimates for PCBs.

**TP009 Evaluation of the effects of ethinylestradiol and chlorpyrifos using an early-life stage Japanese quail toxicity test**

*J. Head, Y. Jeon, McGill University / Department of Natural Resource Sciences; A. Farhat, Environment and Climate Change Canada / National Wildlife Research Centre; L. Bidinosti, E. Boulanger, McGill University / Natural Resource Sciences; O. Hacariz, O. Soufan, McGill University / Institute of Parasitology; J. Xia, McGill University; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre; N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences; D. Crump, Environment and Climate Change Canada / National Wildlife Research Centre*

Birds are sensitive indicators of ecosystem health, but avian toxicity data for many chemicals of environmental relevance are limited. The overall goal of our research project is to develop early-life stage (ELS) avian toxicity tests for rapidly screening chemicals of ecological and regulatory concern. Here, we use our recently developed standardized egg injection protocol to assess the effects of two endocrine disrupters – ethinylestradiol [EE2] and chlorpyrifos [CPF] – on organismal and molecular level end points in ELS Japanese quail (JQ). The chemicals were dissolved in dimethyl sulfoxide and injected into the air cell of JQ embryos prior to incubation at 0, 0.33, 3.33, and 33.3 µg/gegg for EE2, and 0, 0.4, 4, and 40 µg/g egg for CPF. The highest concentration chosen for each test compound was predicted to result in ≤20% mortality. Liver tissue was collected from a sub-set (n=5/dose group) of embryos at mid-incubation (day 9) for subsequent ‘omics and analytical chemistry analyses. The remaining embryos were examined on day 16 (1-2 days prior to hatch) for deformities, growth and health metrics. Mortality was low across all treatments, ranging from 3% for the vehicle group, to 14% and 9% for the high doses of EE2 and CPF, respectively. Exposure to both chemicals led to a significant reduction of embryonic growth and CPF caused an increase in gallbladder size and incidence of deformities of the feet and spinal cord. Analysis of RNAseq data from mid-incubation embryos is currently underway, and samples will be subjected to metabolomics, proteomics and histological analyses as well. The use of avian embryos prior to hatch helps address the need to replace live animal tests with alternative approaches for chemical screening. The co-determination of apical and ‘omics end points will greatly contribute to ecological risk assessments and the development of adverse outcome pathways. This study is part of the EcoToxChip project (www.ecotoxchip.ca).

**TP010 Rodenticide burdens in several species of raptors collected in the Southeastern US**

*A. Ball, J. Thomas, Queens University of Charlotte; D. Blauch, Davidson College; S.M. Weir, Queens University of Charlotte / Biology*

Rodenticides have routinely been found in raptor tissues around the world and occasionally these burdens have been associated with mortality events. Monitoring is an important mechanism for discovering burdens that may be associated with lethality or acute toxicity. We began a monitoring project in collaboration with a raptor rehabilitation facility to monitor rodenticides in the livers of raptors that arrived deceased to the facility or were unable to be rehabilitated. We tested for the presence of two first generation rodenticides (diphacinone, chlorophacinone) and three second generation rodenticides (brodifacoum, difenacoum, bromadiolone). Liver samples were ground and extracted with acetonitrile. Concentrated samples were cleaned up with a QUEChERS kit and extracts were analyzed on an LCMS. We analyzed 44 liver samples from 10 species for rodenticide residues. Rodenticide residues were generally low, and no detectable residues of either diphacinone or chlorophacinone occurred in our samples. Residues of brodifacoum were more common while detections of the other SGARs were also fairly low. The number of individuals out of 44 with detectable levels of difenacoum, bromadiolone, and brodifacoum were 1, 1, and 27, respectively. Average recoveries of diphacinone, chlorophacinone, difenacoum, and brodifacoum were all greater than 89% (range: 89.5-102.5%). Recoveries of bromadiolone were consistently lower and averaged 40%. There were certain species with a high rate of detection of brodifacoum. Detections of brodifacoum were > 75% of samples in barred owls, great horned owls and red-shouldered hawks. Red-tailed hawks (40%) and Cooper’s hawks (33%) had lower detections, but also generally smaller samples sizes. The only raptor with more than 3 samples analyzed and no detections was the eastern screech owl. Over 69% of detections of brodifacoum in owl samples were within (or exceeded) a threshold of brodifacoum residue associated with a 10-20% risk of acute toxicity. Rodenticide exposures associated with a risk of acute toxicity appear to be common and warrant further investigation for raptors in the SE United States.

**TP011 Working towards the recovery of the endangered Aplomado Falcon in south Texas: Are persistent organic pollutants a current concern?**

*C. Hidalgo, M.A. Mora, Texas A&M University / Wildlife and Fisheries Sciences; J. Sericano, Texas A&M University / Geochemical and Environmental Reaserch Group*

Addled Eggs from the endangered Northern Aplomado Falcon were collected annually during 2004-2017, from Laguna Atascosa National Wildlife Refuge and Matagorda Island in south Texas. Eggs were analyzed for persistent organic pollutants, including PCBs, PBDEs, and organochlorine pesticides. Eggshells were measured to determine thickness and to correlate with p,p-DDE concentrations. Our hypothesis is that environmental contaminants in Aplomado Falcon eggs have decreased significantly over time and that eggshell thickness values are near pre-DDT measurements. The 60 egg homogenates were extracted, cleaned- up, and analyzed by gas chromatography-mass spectrometry. Eggshell thickness of 137 shells was measured three times around the equator with a Starrett micrometer. Eggshell thickness varied from is 0.206 mm to a maximum of 0.320 mm. Contaminant concentrations were correlated with eggshell thickness. We suspect that eggshell thickness is strongly correlated with p,p'-DDE concentrations, but these analyses are pending. The last reported contaminant concentrations in eggs of Aplomado falcons from south Texas were from 1999 to 2003, with a mean of 821 ng/g ww for p,p'-DDE and 1228 ng/g ww for PCBs. Eggshell thickness decreased slightly with higher contaminant concentrations. This study will provide an update from eggs collected between 2004- 2017. The Northern Aplomado Falcon population in Texas has been steady at over 30 breeding pairs since 2011, but has not grown significantly. This analysis will provide necessary information to determine if contaminants may be impacting population growth and to assess the quality of habitat across the Aplomado Falcon's range.

**TP012 Transcriptional characterization of the effects of polycyclic aromatic compounds (PAC) in double-crested cormorants during embryonic development**

*S.J. Wallace, Institut National de la Recherche Scientifique / Centre Eau Terre Environnement; S. de Solla, Environment Canada / Ecotoxicology and Wildlife Health Division; P. Thomas, Environment and Climate Change Canada / National Wildlife Research Centre; V.S. Langlois, INRS / Centre Eau Terre Environnement*

Double-crested cormorants (*Phalacrocorax auritus*; DCCO) are colonial waterbirds that are more often included in toxicological studies and yet little is known about their transcriptome regulation during embryonic development. Studying how genes change throughout early development is imperative for understanding normal gene control during organogenesis and other developmental mechanisms. Transcriptional developmental profiles can also help in establishing baselines prior to contaminant disruption and can assist in identifying mechanisms of action. The research objectives of this study were 1) to establish the expression profiles of several key genes during DCCO early development and 2) to assess the effects of polycyclic aromatic compounds (PAC) to DCCO egg stage. To do this, 150 DCCO eggs were collected from Mohawk Island in Lake Erie, a relatively uncontaminated reference site. The eggs were artificially incubated for a maximum of 24 days (from fertilized eggs to 4 days prehatching DCCOs). Five embryos were sampled every 4 days for a total of 6 time points. Embryos were sampled as either whole body or specific tissues according to developmental stages. Targeted qPCR analyses displayed that the expression of genes involved in xenobiotic metabolism, antioxidant defense, and thyroid hormone pathways change throughout development. Complementary PAC exposures were conducted in the developing DCCO. DCCO fertilized eggs were exposed *in ovo* to a range of dilutions of coal tar extracts containing PACs. Genes associated with xenobiotic metabolism increased midway through incubation (Day 12); however, the expression levels returned to normal once the birds reached the hatching stage. Taken together, DCCO embryos are more sensitive to PAC exposure during the first X days post-fertilization, but then can metabolize PACs by hatch. Identification of transcriptomic profiles throughout embryonic development can help better relate exposure of metabolizable contaminants with biological effects.

**TP013 An investigation of lethal and non-lethal domoic acid exposure in loons in California**

*C. Gibble, California Department of Fish and Wildlife / Office of Spill Prevention and Response; R. Duerr, International Bird Rescue; M. Miller, California Department of Fish and Wildlife / Office of Spill Prevention and Response; R. Kudela, University of California, Santa Cruz / Ocean Sciences*

Beginning in April 2017, an unusually large number of dead loons were found between Ventura and Los Angeles County in California during systematic beach surveys, and live stranded loons were reported in large numbers at local wildlife rehabilitation centers (Santa Barbara Wildlife Care Network and International Bird Rescue; IBR). Concurrent to this increase in stranded birds, there was a large bloom of *Pseudonitzschia* spp. with domoic acid (DA) toxin production affecting the Santa Barbara Channel area. IBR received 117 live loons between April 4 and May 30, 2017. Loons that entered rehabilitation displayed obtunded to stuporous mentation. Only nine loons showed typical neurologic clinical signs of DA intoxication such as tremors or seizures at admission. Twelve birds (10.3%) died in the first 24 hours despite supportive care. Birds that survived the first few days quickly re-attained waterproof plumage, normal body weight and blood values, and 49 loons (41.9%) were successfully released; however, 56 loons (47.9%) never became releasable due to ongoing abnormal behavior or injuries related to beaching, and were later euthanized. In order to characterize changes to the avian brain after exposure to DA, the brains of six loons euthanized at IBR due to long-term obtundation of up to 85 days duration, were collected for histology, including one bird where the brain grossly appeared atrophied. The California Department of Fish and Wildlife Marine Wildlife and Veterinary Care and Research Center (MWVCRC) performed systematic necropsies on beachcast carcasses (n=14), and samples were collected for histopathologic examination. Because many birds showed typical evidence of DA intoxication on gross necropsy, including congestion in the brain and other major organs, a subset (n=7) were analyzed for DA in collaboration with University of California, Santa Cruz (UCSC). Seven out of 7 birds examined at the MWVCRC tested positive for DA toxin at UCSC. Brains collected during gross necropsy at MWVCRC from beachcast carcasses were also examined for acute exposure to DA. Gross and histological results were reviewed and compared to highlight the differences between lesions due to acute lethal DA exposure and lesions that develop over time subsequent to an acute non-lethal exposure. Currently, little is known about the effects of chronic versus acute DA exposure in seabirds, and our study aims to fill gaps in this body of knowledge.

## Immunoanalytical Technologies: Development and Applications for Environmental Monitoring

**TP014 Fipronil immunoassay: From conception to broad application**

*N. Vasylieva, UC Davis / Entomology; B. Barnych, D. Wang, University of California, Davis; B.D. Hammock, University of California – Davis / Department of Entomology / UCD Comprehensive Cancer Center*

Phenylpyrazole insecticides such as fipronil have been used as replacements for organophosphates. The wide application of fipronil raises concern about environmental contamination and risk for fish, birds, bees and other non-targeted beings. To mitigate ecological risks routine environmental monitoring could help in timely detection of environmental contamination thus preventing at-risk species from exposure. Two sensitive, rapid tests based on antibodies with sensitivities of 0.58±0.06 and 2.6±0.4 ng/mL were developed. In addition to environmental monitoring, occupational medical surveillance is highly desirable in manufacturing facilities where exposure to chemical is significant. Identification of urinary metabolites of fipronil may allow development of affordable, cheap and rapid procedures for human exposure evaluation. Therefore, we developed a fast and easy approach for synthesis of hydroxy-fipronil, a potential urinary metabolite of fipronil. This standard was used to develop a sensitive analytical LC-MS/MS method with a limit of quantification of 0.4 ng/mL. Fipronil sulfone and hydroxy-fipronil were quantified in urine samples from fipronil treated rats. Fipronil sulfone concentration centered around 20 ng/mL, while the concentration of hydroxy-fipronil was dose-dependent ranging in 10-10000 ng/mL, therefore being a more sensitive marker of fipronil exposure. Immunoassays developed to fipronil also showed cross-reactivity to hydroxy-fipronil. We showed that immunoassay can measure fipronil and its metabolites in samples at levels relevant for human exposure monitoring. With fipronil crisis occurred in Europe in 2017, both the reagents for the immunoassay and a standard for hydroxy-fipronil are in high demand among international profit and non-profit organizations. The reagents are being applied for commercial kits and rapid tests production, instrumental analytical methods development and for monitoring of food and environmental samples. Fipronil immunoassay is also currently used by USGS for field studies.

**TP015 The Application of Monoclonal Antibody-Based Biosensor Analysis for Rapidly Quantifying PAH Concentrations in Porewater at Contaminated Sediment Sites**

*M.A. Unger, G.G. Vadas, Virginia Institute of Marine Science / College of William and Mary / Aquatic Health Sciences; M. Vogelbein, Virginia Institute of Marine Science / Aquatic Health Sciences; K.M. Prossner, Virginia Institute of Marine Science*

Advances in biosensor technology allow near real-time measurement of contaminants at sub-ppb concentrations in small volume (< 5 mL) aqueous samples providing spatial and temporal resolution of contaminants at scales not easily attainable by traditional analytical methods. Porewater measurements are an ideal application of this technology and have been shown to be important for evaluating the transport, bioavailability and toxicity of PAH in sediments. Correlations between polycyclic aromatic hydrocarbon (PAH) concentrations measured in porewater samples by biosensor (< 1 µg/L to > 600 µg/L) and those measured by GC-MS were excellent and the results can be used to evaluate contaminant distribution, transport and bioavailability. PAH concentrations in porewater samples were measured in the field within minutes after collection to map the spatial distribution of PAHs at contaminated sites undergoing different stages of remediation in the Elizabeth River, VA. Analysis of porewater samples collected at various depths by drive-point piezometer allowed vertical profiling of PAH concentrations within sediments suggesting the input of contaminated groundwater at depth and advective mixing with less contaminated surface water. The ability to measure low concentrations in small volume samples also allowed the collection and analysis of seepage meter output on an hourly basis to demonstrate that tidal pumping and advection were controlling PAH flux to the water column. Average biosensor concentrations were similar to concentrations measured by passive sampling but allowed finer temporal resolution to evaluate the tidal driven mechanisms controlling PAH transport on an hourly scale. The abundant data collected by biosensor allowed a direct comparison of sites under various stages of dredging or capping to evaluate remediation effectiveness and to develop better long-term remediation strategies where advection may play an important role in contaminant transport. At tidally influenced sites, remediation plans need to address advection of surface waters and mixing within contaminated sediments as an important transport mechanism that may hinder remediation success. Contaminant concentrations in porewater should be evaluated as an important factor contributing to sediment toxicity and flux to overlying waters. New antibody-based biosensor technology now provides a more rapid and economical method to make these aqueous phase measurements.

**TP017 Isolation of Ultra-specific Single Domain Antibody for the Detection of Sulfadimethoxine**

*H. Yang, University of California, Davis / Department of Entomology and Nematology; H. Meng, Jiangsu University; X. Zhang, Henan Agriculture University; L. Guo, X. Yu, K. Wen, China Agricultural University; B.D. Hammock, University of California, Davis / Department of Entomology / UCD Comprehensive Cancer Center; Z. Wang, China Agricultural University*

Sulfadimethoxine (SDM) is a long-lasting sulfonamide antimicrobial medication frequently used in veterinary medicine throughout the world. To protect consumers from the risk related to SDM residue in animal derived food, maximum residue limits has been established in many countries. Immunoassays have the advantages of low cost, high sensitive and speed to detect residue in a variety of samples, but most antibodies produced in previous reports cannot distinguish SDM from other sulfonamides due to their similar structure. For this reason, we constructed a single domain antibody (sdAb) library from immunized alpaca and obtained an ultra-specific and sensitive anti-SDM sdAb (H1-17) by a well-designed biopanning strategy. H1-17 could only bind to SDM with negligible cross-reactivity value to other 28 kinds of sulfonamides. In H1-17 based indirect competitive ELISA, the 50% inhibition concentration for SDM was 1.1 ng $mL^{-1}$ in assay buffer and the detection range was from 0.36 to 3.63 ng $mL^{-1}$. To the best of our knowledge, this is the first time that SDM specific antibody was produced. The antibody developed by this technique provide means for developing extremely specific and sensitive analytical assays for measurement of SDM.

## Cradle to Grave Impacts of Nanotechnology

**TP018 Effects of a human food additive, titanium dioxide nanoparticles E171, on *Drosophila melanogaster* – a 20 generation dietary exposure experiment**

*B. Jovanovic, Iowa State University / Natural Resource Ecology and Management; N. Jovanovic, V. Cvetkovic, Faculty of Sciences and Mathematics University of Niš / Biology and Ecology; S. Matic, S. Stanic, University of Kragujevac / Biology and Ecology; T.L. Mitrovic, Faculty of Sciences and Mathematics University of Niš / Biology and Ecology*

Although a recent human safety reevaluation of food grade E171 $TiO_2$ was performed by a European Food Safety Authority, not many new data were considered and a major lack of multigenerational studies with reproductive endpoints was noted. In this study, we exposed fruit flies to an estimated daily human E171 consumption concentration for 20 generations. Dietary exposure of 20 consecutive generations of *D. melanogaster* to E171 resulted in a change in normal developmental and reproductive dynamics, reduced fecundity after repetitive breeding, increased genotoxicity, and the appearance of aberrant phenotypes. This effect can be seen as one of the classical adaptations of the fruit fly population to a stressor. A pattern that was gradually observed over the 20 generations of flies was shorter developmental time coupled with higher fecundity and egg to adult viability in virgin females, but reduced fecundity at subsequent mating events Marks of adaptive evolution and directional selection were also exhibited. The larval stages were at a higher risk of sustaining damage from E171 as they had a slower elimination rate and therefore accumulated 10 times the quantity of $TiO_2$ compared to adults. This is particularly worrisome, since among the human population, children tend to consume higher daily concentrations of E171 than adults do. The genotoxic effect of E171 was statistically significantly higher in each subsequent generation compared to the previous one. Aberrant phenotypes were likely caused by developmental defects induced by E171 since the phenotypic features were not transferred to any progeny even after 5 generations of consecutive crossbreeding. Therefore, exposure to E171 during early developmental period carries a higher risk of toxicity, and again, in the human population, fetuses and young children would be the most endangered cohort. The fact that the daily human consumption concentration of E171 is able to interfere with and influence fruit fly physiological, ontogenetic, genotoxic, and adaptive processes certainly raises safety concerns.

**TP019 Synthesis And Characterization Of Carbon Nano-particles From Soot And Dates Fruit (Phoenix dactylifera)**

*A.S. Omoogun, University of Lagos, Department of Chemistry*

Carbon nanoparticle was synthesized from lamp soot, petrol soot and diesel soot. Carbon dots was also gotten from (*Phoenix dactylifera*) by microwave-assisted method. The synthesized carbon nanoparticles were characterized using FT-IR and the carbon dots was also characterized using UV – visible spectroscopy and luminescent study. The FT-IR of petrol soot, diesel soot and lamp soot shows IR absorptions, which indicate the functional groups present. The UV – visible spectra of the carbon dots showed absorption peaks. Photoluminescence study of the carbon nanoparticles from petrol soot, diesel soot and lamp soot revealed a characteristic of green and blue luminescence and also with that of carbon dots from date fruit (*phoenix dactylifera*) which showed a characteristic of green luminescence.

**TP020 Microbial Community Responses to Silver Nanoparticles in Freshwater Sediments: A Potential Risk to the Aquatic Ecosystem Health**

*J. Kusi, P.R. Scheuerman, K.J. Maier, East Tennessee State University / Department of Environmental Health Sciences*

Silver nanoparticles (AgNPs) are among nanomaterials increasingly incorporated into consumer products due to their antimicrobial properties. There are greater concerns about potential antimicrobial effects of AgNPs in aquatic ecosystems following a recent detection of the nanoparticles in treated municipal wastewater. Since treated wastewaters are released into surface waters and metals in aquatic systems eventually settle in sediments, we examined microbial community responses to AgNPs. We treated sediments from a local stream with different concentrations of AgNPs coated with either citrate or polyvinylpyrrolidone. Heterotrophic plate count, microbial enzyme assays, and community level physiological profiling (CLPP) using BIOLOG$^{TM}$ microplates were carried out to determine AgNPs effects on the microbial community. Each type of AgNPs exhibited more than a 60% decrease in microbial growth and glucosidase activity in exposed sediments at 0.431 mg Ag/kg with median inhibition concentrations (IC50) of 0.084 mg Ag/kg compared to the control sediment, but alkaline phosphatase activity was not affected by either AgNPs. CLPP results showed that microbial functional diversity and substrate richness were inhibited by AgNPs affecting carbon source utilization patterns. Principal component analysis demonstrated that microbial metabolic fingerprint patterns of exposed sediments were clearly different from the control sediment, suggesting that the ability of the microbial community to utilize different carbon sources or decompose organic matter decreased in the exposed sediments. The nominal concentrations at which inhibition occurred are below expected AgNPs concentrations in freshwater sediments. This implies that the growing application of AgNPs in consumer products may alter microbial communities in aquatic ecosystems, which may affect the quality of surface waters.

**TP021 Bioavailability of nanoparticles in eastern mosquitofish and freshwater snails following a 9-month exposure in wetland mesocosms**

*B. Castellon, Baylor University / Biomedical Studies; B. Perrotta, Baylor University; M. Simonin, S.M. Anderson, E.S. Bernhardt, Duke University / Biology; R.S. King, Baylor University / Department of Biology; C.W. Matson, Baylor University / Environmental Science*

Engineered nanomaterials such as metallic nanoparticles (NPs) are ever more widely produced, used and released into surface waters, which may pose a risk to human and ecosystem health. While there is a growing body of research on the toxicity of NPs, risk assessments must account for the bioavailability of NPs at environmentally relevant exposure concentrations and in complex ecosystems. Here, we present results from a study in replicated outdoor wetland mesocosms exploring the bioavailability of metallic NPs in eastern mosquitofish (*Gambusia holbrooki*) and two freshwater pond snails (*Physella acuta* and *Lymnaea* sp.). These aquatic taxa were exposed weekly to pulse doses of either gold (Au) NPs (19 mg per week and primary particle size of 11.8 nm), large or small cerium dioxide ($CeO_2$) NPs (19 mg per week, 185.3 nm and 3.8 nm for large and small $CeO_2$ NPs, respectively), copper hydroxide NPs from Kocide 3000 (3588 mg N mg per week, 118.3 nm), or no NP controls. The Au NP, Kocide 3000 and control groups were also tested with or without weekly nutrient additions (88 mg N, 35 mg P per week) as a covariate. There were 3 mesocosm replicates for each unique treatment group. We quantified the accumulation of NPs in tissues quarterly using ICP-MS over the 9-month experiment (i.e. at 3, 6 and 9 months). During sampling, individuals were euthanized and preserved either immediately or after a depuration period of up to 7 days in clean water. Our results at 9 months indicate that *Physella* accumulated more NPs than *Lymnaea*, and both snails accumulated more NPs than *Gambusia*. The accumulation of copper (after subtracting control background levels) in all taxa was 1-3 orders of magnitude higher than Au or Ce, despite a similar NP dose mass, with *Physella* at the highest relative ratio and *Gambusia* the lowest. In snails, the small $CeO_2$ and Au NPs accumulated equally, both at significantly higher levels than large $CeO_2$ NPs, while in fish the small and large $CeO_2$ NPs and Au NPs all accumulated equally. Fish fully depurated copper NPs and both $CeO_2$ NPs within 12 hours, but were only able to depurate about 68% of the accumulated Au NPs even after 7 days. Preliminary results from the 6-month time point indicate the fish were at the same NP concentration for Au and $CeO_2$ NPs, demonstrating NP accumulation steady state was reached by 6 months. Finally, nutrient additions did not significantly influence long-term NP accumulation or retention.

**TP022 Nano-titanium dioxide enabled products – A review of current status and beyond from a life cycle perspective**

*F. Wu, University of Wisconsin, Madison / Chemical, Biological and Environmental Engineering; A. Hicks, University of Wisconsin, Madison / Civil and Environmental Engineering*

Titanium dioxide ($TiO_2$) nanoparticles (NPs) are ranked in the top three most produced nanomaterials (NMs) worldwide, with applications as consumer products such as cosmetics, including sunscreens, were among the top usage at 70–80%, followed by plastics (20 %), paints (10–30 %), and cement (1 %). To improve the state of knowledge on the overall sustainability of nano-$TiO_2$ enabled products, the potential impact of nano-$TiO_2$ to human and environmental health should be assessed during their releases into main environmental compartments (water, air, and soil) throughout their lifetime (including manufacture, use, and disposal). Life cycle assessment (LCA) is a highly qualified tool quantifying all relevant environmental impacts of a product from extraction of the raw materials through its production and use up to its final disposal, which has been recognized for systematically evaluating the potential environmental impacts of engineered nanomaterials (ENMs) for the past decades. However, the large variety of existing ENMs and their unique physicochemical properties enhance the complexity and limitations of applying LCA on ENMs specifically. In this review poster, we present an overview of the current LCA performed on nano-$TiO_2$ enabled consumer products, synthesis methods, and identify the needs for future improvements of current progress. Characterization factors (CF) derived for $TiO_2$ NPs for use during LCA are summarized, and potential shortcomings are discussed and recognized. In addition, environmental concentrations and the potential toxicity of $TiO_2$NPs are identified during each of the main routes of NP releases. Based on this analysis, recommendations for LCA to be applied on nano-TiO2 enabled products are provided, which can also extrapolate to other types of NMs for use in LCA.

**TP023 Importance of dissolved silver in the toxicity of silver nanoparticles towards algae**

*L. Zhang, HKUST Shenzhen Research Institute; W. Wang, Hong Kong University Sci. Technol. / Department of Ocean Science*

Silver nanoparticles (AgNPs) are employed in a variety of consumer products and medical applications due to their antibacterial properties, causing increased discharges of AgNPs into aquatic environment and thereby posing potential hazards to aquatic organisms. Despite the extensive studies on AgNP toxicity, it is still debatable whether the toxicity is mediated by nanoparticle specific effects or by dissolved Ag. This study investigated the toxic effects of citrate-coated AgNPs with different sizes toward a freshwater phytoplankton *Euglena gracilis*, and specifically evaluated the contribution of the released Ag to the toxicity. Our results showed that smaller AgNPs, which dissolved much faster, exhibited greater toxicity to the algae. By using an $Ag^+$ selective probe whose sensing mechanism was based on an aggregation-induced emission process, we visualized the cellular distribution of silver ions using confocal laser scanning microscopy (CLSM). Compared with the 60 nm AgNPs, the 20 nm AgNPs were more prone to solubilize, and more soluble Ag was internalized. However, the internalization of silver ions was dramatically inhibited in the cells exposed to AgNPs or $Ag^+$ by the addition of cysteine. Besides, the average soluble Ag concentrations of both AgNPs at 50% inhibition during exposure time were comparable to those of silver nitrate, and no conclusive evidence of AgNP internalization was observed using transmission electron microscope. Our results therefore strongly suggested that the toxicity of AgNPs toward the algae was driven by release of silver ions.

**TP024 In vivo biotransformation, transportation and biodistribution of silver nanoparticles in Daphnia magna**

*N. Yan, Hong Kong University Sci. Technol.; W. Wang, Hong Kong University Sci. Technol. / Department of Ocean Science*

Silver nanoparticles (AgNPs) have been extensively applied in different fields of our daily life and incorporated into a wide variety of consumer products due to their excellent antibacterial properties. The proliferation of applications and products containing NPs will inevitably result in the release of these nanomaterials into the environment, which will interact with aquatic organisms, possibly posing hazards to aquatic ecosystems. Nevertheless, differentiating AgNPs and $Ag^+$ in complicated biological matrix and its dissolution remains a bottleneck in our understanding of AgNPs behavior in living organisms. Here, we for the first time visualized the distribution of AgNPs and $Ag^+$, and conducted time-dependent monitoring of the dissolution processes of AgNPs in *Daphnia magna* based on the novel aggregation induced emission method. Besides, the transportation and biodistribution of AgNPs and $Ag^+$ were monitored. We demonstrated that the ingested AgNPs were dissoluted to $Ag^+$, which was heterogeneously distributed in daphnids, with much higher concentrations in the anterior gut. At dissolution equilibrium, a total of 9.7% and 8.3% of ingested AgNPs was released as $Ag^+$ for 20 nm AgNPs and 60 nm AgNPs, respectively. Further, $Ag^+$ was found to across the gills and enter the daphnids, which may be a potential pathway leading to AgNPs toxicity. Our findings provided fundamental knowledge about the transformation of AgNPs and distribution of $Ag^+$ in daphnids.

**TP025 Silver-selenium interaction and its effect on selenium metabolism studied using the Rainbow trout cell lines RTgutGC and RTL-W1**

*D. Chanda, M. Minghetti, Oklahoma State University / Integrative Biology*

Due to its anti-microbial properties, silver (Ag) has been used for medical and commercial purposes efficiently for several decades. With the increasing demands and use of silver containing products, its long-term adverse effects on human and environmental health is a concern. For instance silver is known to be highly toxic to aquatic species. Moreover, recent research in mammalian cells has clearly indicated detrimental inhibitory effects on selenoenzymes. Selenoproteins are a group of proteins incorporating selenium (Se) as a structural and catalytic co-factor. Due to their role in removal of reactive oxygen species, as well as protection against oxidative damage to cells, they are considered as vital enzymes. Therefore, any disruption of Se homeostasis can be detrimental to organismal health. Our primary objective is to test the inhibitory effects of Ag exposure in the form of ions and nanoparticles on Se homeostasis and selenoprotein function using fish cell lines derived from the Rainbow trout (*Oncorhynchus mykiss*) gut (RTgutGC) and liver (RTL-W1). Therefore, following exposure to non-toxic and moderately toxic (EC10) $AgNO_3$ and Ag nanoparticles doses of exposure, the intracellular Se concentration will be evaluated by ICP-MS. Selenoproteins (Glutathione peroxidase, thioredoxin reductase and selenoprotein P) function will be evaluated by measuring their mRNA levels and enzyme activity post exposure. In conclusion, this study will look at the possible deleterious effects of silver causing disruption of selenium metabolism in fishes and will describe the mechanism behind the toxicity for such compounds.

**TP026 Particle size and surface properties that influence nanoplastics toxicity**

*A. de Souza Machado, Freie Universität Berlin / Institute of Biology; W. Kloas, Leibniz-Institute of Freshwater Ecology and Inland Fisheries; M. Cooper, J.B. Bachelier, T. Davis, E. Faltin, Freie Universität Berlin; C. Zarfl, Eberhard Karls Universität Tübingen / Center for Applied Geoscience; M.C. Rillig, Freie Universität Berlin*

Environmental contamination with microplastics (plastic < 5 mm) is potentially one of the most long-lasting current pollution problems of our planet. The degradation and disintegration of large microplastics generate nanoplastics, whose accumulation in organisms is of great concern for two main reasons. Firstly, nanoplastics are small enough to potentially cross most biological barriers to environmental contaminants, such as cellular membranes and cell walls, which implies a broad range of potential toxicity targets. Secondly, nanoplastics might present various surface electrical charges that determine the interaction of such particles with biological systems. Thus, while nanoplastics, due to their size, can enter the food web via a higher number of target organisms and taxa compared to larger plastic particles, the reactivity of nanoplastics to membranes, uptake sites and toxicity targets might depend on the nanoplastic surface properties. In order to elucidate the relationship between nanoplastic properties and toxicity we exposed the eukaryote model *Mucor fragilis* to a wide range of concentrations of 12 different polystyrene nanoparticles in liquid culture media. Biomass growth, hyphal reactive oxygen species, and antioxidant capacity were analyzed after 14 days. Ecotoxicological dose-response parameters ($EC_{50}$s, NOEC, LOEC) were determined as a function of particle size (categorical: 25 nm, 50 nm, 100 nm, and 250 nm), surface termination (categorical: COOH, plain, or $NH_3$), nominal mass concentration (up to 1mg $L^{-1}$), particle volume (max ~ $9.6^{-10}$ m³ $L^{-1}$), particle numbers (max ~ $10^{10}$ particles $L^{-1}$), surface area (max 0.01 m² $L^{-1}$) and particle surface Zeta potential (~ -50 mV to ~ +50 mV). While these exposure metrics were good proxies for nanoplastic toxicity, not all were monotonically correlated to the observed responses. For instance, the negatively charged 25 nm particle at 0.1 mg $L^{-1}$ increased fungal biomass. However, at 1 mg $L^{-1}$ all nanoplastic particles triggered cell lysis and biochemical responses that were associated with significantly lower biomass. Therefore, the toxicity of nanoplastics to the chosen eukaryote model could be better explained integrating the multiple exposure metrics into a multivariate space that considers particle size and surface properties. These results are discussed in terms of potential environmental effects of nanoplastics as well as the relevance of choosing the right exposure metrics in nanoparticle toxicology.

**TP027 The characterization of nanoparticle emissions from aerosolized paint dust**

*A. Nored, UAB*

The growing popularity of engineered nanoparticles in manufacturing has raised concerns about the likelihood of exposure to nanoparticles during the end of life phase of nanopaticle infused paint.Weathering and other Destructive situations raise the possibility of both human and environmental exposure to free nanoparticles. This study determines the particle size distribution and total number of particles created using an abrasion technique on paint infused with nanoparticles, and characterizes the dust morphology using scanning electron microscopy(SEM). The results show a particle distribution range from 5-480 nm, with the count median diameter ranging from 43-49nm and a geometric standard deviation of between 1.63-1.67. The SEM images have shown that non-organic materials do both partially and completely escape from organic matter due to abrasion. Exposed particles on the scans are below 100nm. This may be indicative of nanoparticles escaping the parent media.

## Existing, Emerging and New Chemical Contaminants in Changing Polar Environments

### TP028 Does altered contaminant exposure in onshore southern Beaufort Sea polar bears impact immune function relative to those remaining on the sea ice?

*J. Bourque, University of Connecticut / Natural Resources; M.J. Levin, University of Connecticut / Department of Pathobiology and Veterinary Sciences; T. Atwood, USGS / Alaska Science Center; M.A. McKinney, McGill University / Department of Natural Resource Sciences*

A portion of the subpopulation of southern Beaufort Sea polar bears (*Ursus maritimus*) has been documented spending an extended period of time onshore in the summer as Arctic sea ice cover has waned. While onshore, these polar bears have access to alternative food sources, including carcass remains of subsistence-harvested bowhead whales (*Balaena mysticetus*), fish, and birds. These shifting habitat and diet patterns have the potential to alter the exposures to, and effects of, other environmental stressors such as environmental contaminants. We have previously found differences in levels of certain persistent organic pollutants (POPs) in onshore relative to offshore southern Beaufort Sea polar bears, as well as declines in mercury in this subpopulation linked to shifting diet and condition. Mercury (Hg), and certain POPs, including polychlorinated biphenyls (PCBs) and organochlorine pesticides (OCs), have been linked to altered immune function in marine mammals, and gene transcript profiles from previous blood sampling have suggested immune impairment in southern Beaufort Sea polar bears relative to a neighboring subpopulation. This study evaluates immune responses between onshore and offshore southern Beaufort Sea polar bears, and relationships with tissue Hg (and Se:Hg ratios) and POPs concentrations. Protein mediators called cytokines regulate the initiation, maintenance, and amplification of an immune response. Preliminary findings demonstrated that a commercially available multiplex cytokine panel (Millipore© Canine Cytokine panel) cross-reacted with polar bear cytokines, including important pro- and anti-inflammatory cytokines such as tumor necrosis factor alpha (TNFα), interleukin 10 (IL-10), IL-8, and interferon gamma-induced protein 10 (IP-10). This cytokine panel will be used to measure plasma cytokine concentrations for 52 southern Beaufort Sea polar bears sampled in spring of 2013 and 2014. Relationships among cytokines and hair Hg concentrations, hair Se:Hg ratios, and blood POPs concentrations will be assessed and compared for onshore and offshore bears. Results from this study will support ongoing assessments of the impact of changing Arctic environments on the health of polar bears at both the individual and population level.

### TP029 Halogenated flame retardants and temporal trends in polar bears from the two major subpopulations in Hudson Bay, Canada

*A.D. Morris, R.J. Letcher, D. Blair, Environment and Climate Change Canada / Ecotoxicology and Wildlife Health Division; M. Dyck, Government Of Nunavut / Nunavut Department of the Environment*

Flame retardants (FRs) are added to commercial products, including plastics, electronics and textiles with halogenated FRs (HFRs), including polybrominated diphenyl ethers (PBDEs), being known contaminants of Arctic concern. Despite these concerns and increasing international regulation on HFRs, there are few reports of temporal trends of PBDEs and non-PBDE HFRs in wildlife from the North American Arctic. For the present investigation PBDE congeners (25) and non-PBDE FRs (24) were measured in the adipose of southern (SHB; 2007–2016) and western (WHB; 1991–2015) Hudson Bay polar bears to examine spatial and temporal trends. Most of the non-PBDE FRs, with the exception of hexabromocyclododecane (HBCDD) and polybromobiphenyls (BB)-101 and BB-153, were largely below detection limits in both subpopulations. HBCDD was detected consistently in the WHB from 2001–2011 and in the SHB from SHB from 2007–2012 (linear regressions were not significant, $p > 0.10$), but was below detection limits outside of these ranges. BDE-209 was detected infrequently in the WHB from 2003-2012 and in the SHB from 2008–2013; like HBCDD, it has not been detected in recent years (unsuitable for temporal analysis). Of the consistently detected compounds, BDE-47, BB-153 and BDE-153 had the greatest concentrations in both subpopulations. BB-153 was decreasing significantly in the WHB (-1.8%/y; half-life = 38 y) and may be decreasing in the SHB, however the linear regression was not significant (-6.3%/y, $p = 0.22$). The $Sum_4$PBDE (BDE-47, -99, -100, -153) concentrations were increasing relatively rapidly in the WHB (9.1%/y) with a doubling time of 7.6 y, however this relationship was also insignificant in the SHB (1.4%/y; $p = 0.37$). Only BDE-99 yielded a significant linear relationship in the SHB, decreasing at -3.3%/y with a half-life of ~21 y. In contrast, BDE-47, -99, -100 and -153 all increased linearly in the WHB at rates of 7.2 to 9.5%/y with doubling times of 7.3 to 10 y. Further analysis of the WHB trends using piecewise regressions showed that concentrations of $Sum_4$PBDE, BDE-47, -99 and -100 increased rapidly (15–16%/y) from 1991 to their breakpoints (~2000-2003), where trends slowed and/or remained relatively constant (-0.0042–6.0%/y) from 2003 to 2015-2016. The breakpoints for these congeners from the pentabromo-DE technical mixtures correspond well with voluntary national reductions in use and North American bans, and agree with observations in other arctic marine mammals.

### TP030 Subcellular distribution of trace elements in polar bears (*Ursus maritimus*) livers

*J. Hadrava, Université du Québec à Montréal; B. Barst, McGill University / Dept of Natural Resource Sciences; J. Labrie, Université du Québec à Montréal / Department of Biological Sciences; R. Dietz, C. Sonne, Aarhus University / Department of Biosciences / Arctic Research Centre; N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences; M. Rosabal, Université du Québec à Montréal / Department of Biological Sciences*

Polar bears (*Ursus maritimus*) are endangered marine mammals of the Arctic that occupy top trophic positions. The melting of sea ice in response to global climate change is affecting its natural habitat and reducing its hunting territory. In addition, its apical position in the food chain increases its susceptibility to be exposed to contaminants by bioaccumulation, such as mercury (Hg) or others trace elements. This exposure may affect its ability to cope with environmental stressors or ultimately decrease survival. In this context, we aim to evaluate if the intracellular handling of metals – including rare earth elements – in polar bear hepatocytes represents a toxicological risk. For this purpose, we measured arsenic (As), silver (Ag), cadmium (Cd), lanthanum (La), neodymium (Nd), total mercury (Hg) and thallium (Tl) concentrations in the livers of 9 polar bears collected in Greenland and explored how these elements were distributed at the subcellular level. The livers were subjected to a subcellular partitioning procedure using differential centrifugation, NaOH digestion, and heat denaturation steps, that separate liver cells into five subcellular fractions. These fractions were categorized into putative metal-sensitive (heat-sensitive fractions, mitochondria, microsomes+lysosomes) and detoxified metal compartments (heat-stable proteins, granule-like structure). The presence of trace elements in the metal-sensitive fractions may reflect a toxicological risk for the polar bears. The fractions were analyzed for trace elements by ICP-MS. Results demonstrate that the heat-stable protein fraction is the main fraction involved in detoxification for the six trace elements studied, with up to 60% of the total Cd and Ag accumulated therein. The trace elements were also found in the metal-sensitive fractions, predominantly in mitochondria. Indeed, for all metals analyzed, at least 15% of the total metal accumulated was associated with the mitochondria. The proportions of both As and Tl in the metal-sensitive compartment approached ~60%. Accumulation of As in the metal-sensitive compartment exceeded accumulation in detoxified fractions for certain individuals, whereas this was the case for Tl and Nd for all individuals. These results indicate that polar bears are able to detoxify these trace elements, but this detoxification is not sufficient to prevent their association with physiologically sensitive sites, which could compromise polar bear health.

**TP031 Can faeces serve a proxy for the polar bear's contaminant body burden?**

*V.S. Langlois, M. Dominique, Institut National de la Recherche Scientifique / Centre Eau Terre Environnement; R.J. Letcher, Environment and Climate Change Canada / Ecotoxicology and Wildlife Health Division; M. Branigan, Government of Northwest Territories; P. van Coeverden de Groot, S.C. Lougheed, Queens University / Biology Department; A. Rutter, Queens University / School of Environmental Studies*

Over the last decades, evidence has accrued showing that Arctic ecosystems are exposed to contaminants, such as persistent organic pollutants (POPs) and mercury. These contaminants are of concern because of their persistence, toxicity, and bioaccumulation rate. Polar bears, as apex predators, can biomagnify such contaminants and are a good indicator of Northern environmental pollution. Several studies have quantified contaminant body burden in polar bears, but these studies have relied on invasive methods, including collection of fat, liver, teeth, or kidneys. The novelty of this project centres on using a non-invasive and robust monitoring method using polar bear faeces to quantify contaminant loads. The objective of this work is to establish a database of contaminant concentrations in bear tissues to predict human exposure and risks for local indigenous people (e.g., via traditional subsistence hunting). Preliminary data show high levels of total mercury and metals in polar bear's faeces. Complementary analytical analyses (e.g., PCBs, PBDEs, PAHs, organic pesticides, and MeHg) are in progress. Our study will facilitate contaminants monitoring in polar bears while minimizing contact between humans and bears.

**TP032 Subpopulation- and Compound-Specific Temporal Changes of Perfluoroalkyl Acids and Precursors in Polar Bears From Hudson Bay**

*R.J. Letcher, A.D. Morris, D. Blair, Environment and Climate Change Canada / Ecotoxicology and Wildlife Health Division; M. Dyck, Government Of Nunavut / Nunavut Department of the Environment*

Perfluoroalkyl carboxylic acids (PFCAs) and sulfonates (PFSAs) in the environment include perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA) as well as their precursors. PFOS, PFOA and perfluorohexane sulfonate (PFHxS) have been increasingly regulated and phased-out, and have been replaced by new PFAAs such as shorter-chain analogues (e.g. perfluorobutane sulfonate (PFBS) and carboxylic acid (PFBA)), perfluorooctane-1-ethylcyclohexyl sulfonate (PFEtCHxS) and other precursors of perfluoroalkyl acids (PFAAs). Hudson Bay is an Arctic contaminant and climate change hot spot and polar bears (*Ursus maritimus*) are a top marine-feeding predator. In the present study, compound-specific temporal trends (for all years from 2007 to 2016) were examined in the liver tissue of Hudson Bay polar bears (southern (SHB) and western (WHB) subpopulations). For temporal statistical analysis, compounds were used if detected in >80% of total the samples (n=225) and medians were used to minimize outlier effects. For the SHB bears, PFSAs gradually decreased over time but only the PFEtCHxS and PFOS decreases were significant ($p< 0.05$) with changes of -6.3% and -25% per year, respectively. Although not significant, the PFOS precursor perfluorooctane sulfonamide (FOSA) increased by 1.4% per year. PFBS and the perfluorobutane sulfonamide (FBSA) were quantifiable in only 43% and 18%, respectively, of the samples. PFUdA, PFDoA and PFTrDA decreased 13-14% per year, but the shorter-chain PFOA and PFNA increased by 0.5% and 7.1% per year. PFBA was quantifiable in only 36% of the samples. Different from SHB bears, PFOS in WHB bears remained unchanged, but PFEtCHxS and PFHxS both increased by 5%, and FOSA increased by 18% per year. Similar to the SHB bears, PFBS and the FBSA precursor were both quantifiable in only 25% of the samples. PFUdA, PFDoA and PFTrDA in the WHB bears appeared to decrease 11-15% per year, and in contrast to SHB bears, the shorter-chain PFOA and PFNA appeared to show greater increases of 8.4% and 24% per year. Like the SHB bears, PFBA was quantifiable in only 34% of the WHB samples. These results clearly showed temporal changes or a lack of change in the concentrations of PFAAs and/or their precursors, which differed between bears of the two subpopulations. We are currently examining the source, dietary, etc. factors that may explain these temporal changes in polar bears.

**TP033 Comparison of trends of perfluoroalkyl substances (PFASs) in ringed seals and in seawater across the Canadian Arctic**

*D.C. Muir, M. Houde, A.O. De Silva, Environment and Climate Change Canada / Aquatic Contaminants Research Division; J. Kirk, Environment and Climate Change Canada / Global Tox; C.M. Butt, Sciex / Nicholas School of the Environment; C. Spencer, M. Williamson, Environment and Climate Change Canada*

The ringed seal (*Phoca hispida)* is the most abundant Arctic pinniped with a circumpolar distribution and a key biomonitoring species for the evaluation of contaminants. Early temporal trend studies on perfluoroalkyl substances (PFASs) in liver of ringed seals at two locations in the Canadian Arctic, showed C9–C15 perfluorocarboxylates (PFCAs) had increasing levels during the period 1998-2005 while perfluorooctane sulfonate (PFOS) achieved maximum concentrations in 1998-2000 and declined from 2000 to 2005. Ocean transport of PFASs was proposed as the main route of deliver of PFASs to the arctic marine environment, however, the rapid response to phase out of PFOS suggested the importance of an atmospheric pathway as well. The objective of this study was to compare temporal trend data for PFASs in ringed seals in several widely separate locations in the Canadian Arctic over a 15 to 20 yr period, as well as newly available time trends in ocean waters from the central Canadian archipelago, and with trends in atmospheric concentrations. Ringed seal samples were obtained from subsistence harvesting in four regions of the Inuit Nunangat: Sachs Harbour (NWT), Resolute and Arviat (Nunavut) as well as in Nain (Labrador). Seawater (1L) was collected in Lancaster Sound, near Resolute Bay, between 2005 and 2017 at depths of 10-100m. Seal liver and seawater were analyzed for PFASs by LC-MS/MS. Highest total PFASs (PFOS + C8–C15 PFCAs) in ringed seals over the period 2011-2016 were observed in the more southern locations, Arviat (52 ng/g ww) and Nain (41 ng/g ww), compared to more northern (Sachs Harbour; 30 ng/g; Resolute 24 ng/g). Lowest concentrations of PFOS were generally observed during the period 2005-2010, following a decline from higher levels in the period 1998-2005. Since 2011 PFOS concentrations in liver have increased at Resolute and Arviat by about 2-fold. The trends for PFCAs generally show a similar temporal pattern as PFOS with indications of recent increases particularly at Arviat. In seawater collected near Resolute since 2005, PFOS has declined significantly with an overall disappearance half-life of 4.4 yr. PFOA showed no trend between 2005 and 2017 in seawater. The increase in PFOS in seals is also observed in atmospheric measurements in the Canadian Arctic where PFOS had a doubling time of 2.9 years between 2006 and 2014. Thus trends of PFOS concentrations in ringed seals appear to reflect atmospheric rather than oceanic trends in the Canadian arctic.

**TP034 Engaging Indigenous communities in contaminants research on wildlife: Educational workshops on ringed seal health conducted in Inuit Nunangat**

*D. Henri, Environment and Climate Change Canada; J. Provencher, Acadia University; C. Debets, University of Manitoba; M. Giraudo, Environment and Climate Change Canada; M. Appaqaq, Nunavut Arctic College; L. Martinez-Levasseur, A. Black, Environment and Climate Change Canada; D.C. Muir, Environment and Climate Change Canada / Aquatic Contaminants Research Division; S.H. Ferguson, Fisheries and Oceans Canada / Central and Arctic Region; D. Yurkowski, University of Manitoba; M. Houde, Environment and Climate Change Canada / Aquatic Contaminants Research Division*

The ringed seal is a species of high cultural, economic and nutritional importance for northerners living in Inuit Nunangat (Inuit regions of Canada). Scientists conducting studies of the spatial and temporal trends of legacy and emerging/new contaminants in ringed seals from the Canadian Arctic work towards better understanding the ecology and health of this species, often in collaboration with Inuit community members. This project addresses a shared interest among Inuit and scientific researchers in enhancing communications and northern community capacity building in relation to contaminants research. It engages scientific researchers, Inuit youth, elders, and community members in learning about ringed seals from both Inuit Qaujimajatuqangit (Inuit traditional knowledge) and scientific perspectives through educational workshops. Since 2016, we conducted three educational workshops in collaboration with local schools and Hunters and Trappers Organizations. The main goals of these workshop were to (1) allow scientists working on contaminants in ringed seals to share information about their work with northern residents (with a focus on Inuit youth in particular), (2) provide an opportunity for Inuit elders to share their knowledge with students and researchers in seal ecology and traditional methods for hunting, preparing seals and identifying abnormalities in harvested animals, (3) increase the engagement and interest of northern students and community members in contaminants research, and (4) identify best practices and lessons learned for engaging and communicating with Inuit youth and elders as part of contaminants research. The experience and insights gained from this innovative work can be helpful to scientific researchers, educators, and community members interested in Indigenous engagement in contaminants research on wildlife, and the development of educational opportunities linking Indigenous knowledge and contaminants research.

**TP035 Screening-level risk assessment of methylmercury for non-anadromous Arctic char (*Salvelinus alpinus*)**

*B. Barst, McGill University / Dept of Natural Resource Sciences; P. Drevnick, Alberta Environment & Parks / Environmental Monitoring and Science Division; D.C. Muir, Environment and Climate Change Canada / Aquatic Contaminants Research Division; N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences; G. Köck, Institute for Interdisciplinary Mountain Studies; M. Power, University of Waterloo; F. Rigét, Aarhus University / Dept of Environmental Science; H. Swanson, University of Waterloo*

Arctic char (*Salvelinus alpinus*) is an ecologically and culturally important species of fish distributed across northern regions of the Holarctic. Anadromous forms of Arctic char, those that migrate to and from the sea, are typically lower in mercury concentrations than non-anadromous forms that are restricted to lakes and rivers. Using data from the literature and our own analyses, we performed a screening-level risk assessment of methylmercury for non-anadromous Arctic char. Our assessment included more than 1500 fish distributed across 81 sites. Site-specific mean total mercury concentrations in non-anadromous Arctic char muscle varied considerably from 0.01 to 1.13 µg/g wet weight, with 21% (17 of 81 sites) meeting or exceeding a threshold-effect level in fish of 0.33 µg/g wet weight, and 14% (11 of 81 sites) meeting or exceeding 0.5 µg/g wet weight. Of the sites in exceedance of 0.33 µg/g wet weight, seven were located in Greenland and ten in Canada (Labrador, Nunavut, Yukon). Maximum total mercury concentrations exceeded 0.33 µg/g wet weight at 55% of sites (40 of the 73 sites with available maximum total Hg values), and exceeded 0.5 µg/g wet weight at 28% (20 of 73 sites). Collectively, these results indicate that certain populations of non-anadromous Arctic char may be at risk for methylmercury toxicity. Furthermore, the most contaminated individuals in more than half of the populations may also be at risk. Though the approach used in this study provides a simple statistical assessment of methylmercury risk to non-anadromous Arctic char, it does not indicate actual effects. We highlight the need for laboratory and field studies which evaluate the potential toxic effects of methylmercury in non-anadromous Arctic char, as well as those that aid in the development of a methylmercury toxic-effect threshold specific to this species of fish.

**TP036 Spatial and long-term trends in persistent organic contaminants and mercury in lake trout and burbot from Great Slave Lake, the Northwest Territories**

*M. Evans, Environment and Climate Change Canada / Water, Science and Technology; D.C. Muir, X. Wang, Environment and Climate Change Canada / Aquatic Contaminants Research Division; J. Keating, Environment and Climate Change Canada / Water and Science Technology*

Great Slave Lake, located in Canada's Northwest Territories, is a large (28,568 km$^2$), deep (mean depth 69 m, maximum depth 614 m) lake and can be subdivided into two major ecoregions. The West Basin is relatively shallow, productive, and profoundly influenced by Slave River flow which originates in the more developed regions to the south; the East Arm is substantially deeper, lower in productivity and with small riverine inputs from the Canadian Shield. Long-range atmospheric sources are inferred to be the primary contaminant source to the East Arm while the West Basin also receives Slave River sources. The region is undergoing pronounced warming trends which appear to be affecting productivity and may affect mercury methylation rates and various aspects of fish biology. Here we report on our long-term (1993-2017) investigations of spatial and temporal trends in mercury and persistent organic contaminant concentrations (POCs) in lake trout (*Salvelinus namaycush*) and burbot (*Lota lota*). Overall, mercury concentrations were relatively low in lake trout and slightly higher in West Basin (0.21 ±0.08 µg/g) than East Arm (0.17± 0.10 µg) fish; mercury concentrations were similarly low in burbot (0.16±0.07 µg/g West Basin; 0.14±0.06 µg/g East Arm). Relatively low mercury concentrations in comparison to smaller lakes in the region is attributed to large lake effects including cold waters throughout most of the year and weak watershed inputs and their influences on methyl mercury production. While mercury concentrations exhibited a trend of increase up to ca. 2012, this trend has weakened in recent years as has been observed elsewhere in the north. Legacy POCs concentrations tended to be slightly higher in East Arm than West Basin fish, e.g., considering ΣPCBs, concentrations averaged 12 ± 12 ng/g for West Basin lake trout fillet versus 19 ± 18 ng/g for East Arm trout and 85 ± 55 ng/g for West Basin burbot liver versus 97 ± 62 ng/g for East Arm fish) suggesting that anthropogenic influences from the south were not exerting detectable contaminant effects on West Basin fish. POCs concentrations were in the middle of the range for lakes investigated in northern Canada and the Laurentian Great Lakes. ΣChlordane, ΣDDT, ΣHCH and ΣPCB concentrations have declined significantly ($p < 0.05$) in West Basin lake trout and burbot while significant trends have been detected only for ΣDDT and ΣHCH for East Arm fish. East Arm fish may be slower to show trends in POCs decline because of the longer residence time of its water and the lower concentrations of particulates which may allow POCs to remain in the water column for a longer period of time than in the West Basin. ΣPBDE and ΣPFCA concentrations were low; trend investigations are underway. Overall, mercury and POCs concentrations are low in Great Slave Lake fish; mercury trends are of particular interest as warming trends continue.

**TP037 Investigating the presence and persistence of volatile methylsiloxanes in Arctic sediments**

*D. Panagopoulos, ORISE at USEPA / Department of Indoor Environment; A. Jahnke, Helmholtz Centre for Environmental Research – UFZ GmbH / Cell Toxicology; N.A. Warner, NILU – Norwegian Institute for Air Research / Environmental Chemistry; F. Wong, L. Jantunen, Environment and Climate Change Canada; G. Christensen, Akvaplan-niva AS; M. MacLeod, Stockholm University / Department of Environmental Science and Analytical Chemistry*

Volatile methylsiloxanes (VMS) are a group of organosilicon compounds that are used as carriers in personal care products and in the production of silicone polymers. Concerns have been raised about the persistence of VMS in aquatic environments due to their long residence times in sediments.[1] Reported measurements of the partition ratio between organic carbon and water ($K_{OC}$), the enthalpy of sorption ($\Delta H_{OC}$) and the enthalpy of phase change between octanol and water ($\Delta H_{OW}$) of VMS are subject to large variability, resulting in large differences in calculations of persistence and bioaccumulation. These differences may be as large as 1100-days difference in overall persistence and 1 order of magnitude in concentrations in biota. We collected sediment samples from three areas in the Arctic (Svalbard, Greenland and Canada), and wastewater samples from Svalbard. The samples were analyzed for 3 linear VMS (lVMS): $L_4$, $L_5$, $L_6$, and 3 cyclic VMS (cVMS): $D_4$, $D_5$, $D_6$. We used the measured concentrations of $D_5$ in the wastewater samples to predict concentrations in the sediment and we compared them to measured values. For our modeling calculations, we evaluated two different scenarios: (1) we used the $K_{OC}$ measurements of Kozerski et al. and the $\Delta H_{OW}$ of Xu and Kropscott, (2) we used the $K_{OC}$ and $\Delta H_{OW}$ measurements of Panagopoulos et al.[2-3] The highest concentrations measured for all VMS were observed in Greenland. The predicted concentrations for $D_5$ in scenario 2 were in good agreement with the measured concentrations, whereas in scenario 1, they were almost 2 orders of magnitude lower. Based on our sensitivity analysis, the required changes for the predicted concentrations of scenario 1 to reach the concentrations of scenario 2 ranged from 2 orders of magnitude (emissions rates) to 8 orders of magnitude (density of sediment particles). Such large discrepancies indicate that the differences in the predicted concentrations in the two scenarios are more likely to be attributed to $K_{OC}$ and $\Delta H_{OW}$ / $\Delta H_{OC}$ than in environmental parameters or emission rates.

**TP038 Modeling of bromine chemistry and the boundary-layer depletion of ozone and mercury across the springtime Arctic**

*K. Toyota, A. Ryjkov, Environment and Climate Change Canada; A. Dastoor, Environment and Climate Change Canada / Air Quality Research Division; J. Chen, C. Stroud, A. Lupu, J. Zhang, V. Savic-Jovcic, Q. Zheng, M. Moran, Environment and Climate Change Canada; J. Halfacre, Indiana University Southwest; W. Simpson, University of Alaska Fairbanks; S. Netcheva, Environment and Climate Change Canada; P.B. Shepson, Purdue University / Chemistry; J. Bottenheim, A. Steffen, Environment and Climate Change Canada; C. Moore, Gas Technology Institute; D. Obrist, Desert Research Institute; R. Staebler, Environment and Climate Change Canada; N. Theys, Royal Belgian Institute for Space Aeronomy; C. McLinden, Environment and Climate Change Canada*

Gas-phase bromine radical chemistry is the main driver for the frequent and concurrent depletion of ozone and mercury (Hg) in the polar boundary layer during the spring. Sea ice and its overlying snow cover are broadly understood as the key elements in the production of reactive bromine in polar spring. However, a full characterization remains unsettled on how physicochemical states of snow and ice influence the release of bromine into the atmosphere. Uncertainties in the kinetics and reaction mechanisms of Hg redox chemistry add further complexity to accurately assessing the behavior of Hg during its depletion from air. Three-dimensional (3-D) models, developed to simulate the impact of bromine chemistry on Hg oxidation at both global and arctic-basin regional scales, have generally relied upon indirect representations of the sources, sinks and photochemical transformation of bromine radical species in the polar atmosphere. Within Environment and Climate Change Canada's air-quality model, GEM-MACH, we have developed a process-oriented representation for the coupled bromine-ozone-Hg chemistry and the exchange of bromine, ozone and Hg species between air and snow/ice surface. The model is run at 15-km horizontal resolution in a limited-area domain of the Arctic and is capable of capturing the evolution of high BrO column densities associated with synoptic weather disturbances during polar sunrise as can be seen from satellite. The concurrent depletion of ozone and Hg is simulated by consistent model formulations, where the release of reactive bromine from the frozen surfaces is facilitated by the presence of ozone in air. The concentrations of ozone and speciated Hg measured in the surface air and the vertical column densities of BrO retrieved from ground stations and buoys floating on the ice-covered ocean also allow us to evaluate the model simulations at fine temporal scales even though limited in spatial coverage. Our model framework for simulating the reactive bromine release from the snow/ice cover is found to work reasonably well for the representation of ozone and Hg depletion events across the Arctic region over synoptic and seasonal time scales. The deposition of oxidized Hg from the atmosphere is found to be enhanced particularly under the disturbed weather conditions, as a result of the vertical and horizontal inflow of ozone and gaseous elemental Hg and their chemical conversion in the polar boundary layer.

## Translating Environmental Science into Improved Outcomes and Policy

**TP039 Challenges in Development and Application of Dissolved Oxygen Criteria in Estuarine and Marine Waters**

*J. Flippin, Tetra Tech, Inc. / Center for Ecological Sciences; J.M. Diamond, Tetra Tech, Inc.; S. Roy, Tetra Tech Inc. / Research and Development*

Dissolved oxygen (DO) dynamics in coastal and estuarine systems are complex, often depending on temperature, nutrient availability, photosynthesis, and hydrological characteristics of a distinct waterbody. Advances in continuous monitoring technology are better able to capture the intricacies of DO dynamics but provide some uncertainties for developing appropriate DO criteria for marine and estuarine waters. The Environmental Protection Agency (EPA) released guidance for developing DO criteria for the area between Cape Cod, MA and Cape Hatteras, NC. The methodology-- *Ambient Aquatic Life Water Quality Criteria for Dissolved Oxygen (Saltwater): Cape Cod to Cape Hatteras (EPA 2000)* -- describes calculation of endpoints protective of survival, growth, and larval recruitment in aquatic organisms. The results of continuous exposure laboratory toxicity tests shown in EPA (2000) along with more recent data are used to derive the two most commonly used endpoints. The methodology has been subsequently applied, with some modifications, to estuaries and coastal areas around the country. Case studies from several states demonstrate the use of the original guidance, updates to include recent data, potential for use of alternative endpoints such as behavioral studies and field observations, and site-specific ecological or hydrological data that help to remove some uncertainty of applying laboratory endpoints to derive site- and state- specific DO criteria.

**TP040 Is My Cannabis Product Safe? A Closer Look at the Legal Limits for Residual Solvents**

*A. Nagai, Blankinship & Associates, Inc.*

Recreational cannabis legalization has been growing in popularity over recent years, bringing with it a variety of cannabis-infused products such as vaporizer pens, edibles, and ointments. Such products are made by extracting cannabinoids from cannabis plant material using solvents such as ethanol, butane, and propane. To protect consumer safety, several states have implemented action levels as standards that define the legal limits of residual solvents permitted in cannabis-infused goods. In this presentation, the action levels of California, Colorado, Massachusetts, Oregon, and Washington are reviewed to provide insight to the development, consistency, and applicability of residual solvent limits for cannabis-infused goods across the country. While action levels established by most states were consistent with those adopted by international organizations for residual solvents in pharmaceuticals and based on conservative, health-based approaches, they appeared to be applicable primarily to oral exposures. California was the only state with an additional set of action levels established as air concentrations for inhalable goods; however, the inhalation action levels were based on occupational exposure limits and must be converted to units consistent with those required for laboratory testing (e.g., ug/g) in order to be meaningful. Although action levels established for cannabis-infused goods meant for ingestion generally appear to be protective of human health, consideration must be given to a broader picture of toxicity and exposure in order to reduce potential health impacts associated with other anticipated routes of exposure. Future refinements of residual solvent action levels should consider toxicity via inhalation and dermal exposure, receptors of interest, the magnitude of consumer exposure via consumption of cannabis, and the feasibility of determining regulatory compliance when action levels are expressed in units of measure which are not directly comparable to laboratory results.

**TP041 Translational environmental science: Improving outcomes and policy**

*A. LeHuray, Chemical Management Associates LLC; A. Moghissi, Georgetown University / Department of Microbiology and Immunology*

Translational science has rapidly become an established discipline in medical fields, in which it is described as the non-linear, multi-directional progression of science from "bench" (i.e., basic research) to "bed-side" (i.e., improved outcomes) to "community" (i.e., public understanding). Improved translation from research results to regulatory and practical applications as well as community understanding is demonstrably needed in the multi-disciplinary environmental sciences. Properly understood, one role of translation in the process of developing regulation is the clear separation of policy (societal objectives) considerations from scientific considerations. For example, the use of assumptions, protective safety factors, inter-species extrapolations, and other outcome objectives are part of the translational process and need to be clearly recognized as such. Risk assessment should be understood as a translational tool, separating scientific information from risk management. The historical development of environmental regulation illustrates both successful and less-than-successful translations, and provides guidance for improving the processes of scientific assessment and verification, translation from science to practical outcomes and effective regulation, and improved understanding of the promulgated product.

## Human Exposure to Emerging Environmental Contaminants

**TP042 From biomonitoring to PBPK/PD modeling of Bisphenol A and its analogues: The mixture approach**

*M. Marquès, Universitat Rovira i Virgili / Chemical Engineering, IIPSV; N. González, Universitat Rovira i Virgili / School of Medicine IISPV; R.P. Sharma, Universitat Rovira i Virgili / Departament d Enginyeria Química; M. Martinez Rodriguez, Universitat Rovira i Virgili / Chemical Engineering; J. Rovira, Universitat Rovira i Virgili; M. Mari, Universitat Rovira i Virgili / Chemical Engineering; V. Kumar, Universitat Rovira i Virgili / Chemical engineering department; M. Schuhmacher, Rovira i Virgili University / Departament d Enginyeria Química; J.L. Domingo, Universitat Rovira i Virgili / Laboratory of Toxicology and Environmental Health; M. Nadal, Universitat Rovira i Virgili / School of Medicine, IISPV*

Endocrine-disrupting chemicals are substances of special concern due to their adverse effects for the human health. Among them, bisphenol A (BPA), a chemical widely used for coating in food and drink cans, has attracted most of the attention, being banned in plastic baby bottles in a number of countries. Consequently, BPA has started to be replaced by a number of alternatives, such as bisphenol S (BPS) or bisphenol F (BPF). The present study was aimed at assessing the exposure to bisphenols, the biodistribution in the human body, and finally estimating the potential risk of BPA alternatives. Firstly, the concentrations of these 3 chemicals were determined in foodstuffs collected in different locations, with a special emphasis on the analysis in canned foods. These results were used to assess the cumulative exposure to bisphenols. Human exposure was performed both deterministically and probabilistically taking into account recent food consumption data from the adult population of Spain, by means of the Monte Carlo Risk Assessment (MCRA) software. In parallel, up to 25 people were recruited to build a cohort. A duplicate diet calculated for two days of feeding was purchased. One food basket was provided to each participant, while its duplicate was transported to the lab for analysis. Participants collected 100mL of urine from each micturition along the study, while blood samples were extracted the first day at 8h (fast), 11h, 14h and 17h to further determine the contents of BPA, BPS and BPF. Subsequently, a generic PBPK/PD model will be adjusted to bisphenolic compounds to estimate the concentrations in, at least, 7 body compartments (blood, muscle, skin, richly perfused, adipose, kidney, and liver), in addition to urine and plasma. The results from the duplicate diet study of the present study will be used as model input data, while data from the biomonitoring study of a single adult population will be used for validation purposes. These findings will help elucidate the potential risk of BPA alternatives through food consumption, under a cumulative/aggregated rather than single exposure.

**TP043 Urinary concentrations of environmental phenols and their association with type 2 diabetes in a population in Jeddah, Saudi Arabia**

*J. Li, Wadsworth Center / New York State Department of Health; J. Xue, Wadsworth Center; S. Lin, State University of New York at Albany; K. Kannan, Wadsworth Center / New York State Department of Health / Division of Environmental Health Sciences*

A fewepidemiologic studies suggest that exposure to bisphenol A (BPA) is associated with type 2 diabetes mellitus (T2DM). However, little is known about association between other phenolic endocrine disrupting chemicals (EDCs) and T2DM.In this case-control study,we measured urinary concentrations of 23 phenolic EDCs in 101 individuals from Jeddah, Saudi Arabia, to examine the association of parabens, antimicrobials, bisphenols, benzophenones and bisphenol A diglycidyl ethers with T2DM. Urine samples were collected from 54 T2DM cases and 47 non-diabetic individuals (controls), aged 28-68 years old, during 2015-2016. Unconditional logistic regression was performed to estimate odd ratios (ORs) for the association between diabetes and EDC exposures after adjusting for confounders including age, gender, nationality, smoking status and occupation. Age from 40-59 years (OR 5.56, 95% CI 2.20-14.0) and smoking status (OR 2.92, 95% CI 1.25-6.79) showed significant positive associations with T2DM. After adjusting for potential confounders, we found that T2DM cases had high urinary levels of parabens (i.e., methyl- (MeP), ethyl- (EtP), propyl- (PrP) and 4-hydroxy benzoic acid (4-HB)), bisphenols (i.e., bisphenols A (BPA) and F (BPF)), and benzophenone (i.e., 4-hydroxybenzophenone (4-OH-BP)) relative to the controls. Individuals in the 4th quartile for urinary concentrations of MeP, EtP, PrP, 4-HB and BPF and in the 3$^{rd}$ quartile for BPA and 4-OH-BP showed over a 6-fold increase in the odds of having diabetes compared with those in the first quartile. Overall, our study shows that urinary levels of multiple phenolic EDCs were associated with increased risk for diabetes. Further prospective studies are required to verify these associations.

**TP044 Parabens in human urine from several Asian countries, Greece, and the United States**

*M. Honda, Wadsworth Center / New York State Department of Health; M. Robinson, Wadsworth Center / New York State Department of Health / Department of Environmental Health Sciences; K. Kannan, Wadsworth Center / New York State Department of Health / Division of Environmental Health Sciences*

Parabens, esters of para-hydroxybenzoic acid, are commonly used as antimicrobial preservatives in cosmetics and personal care products. Although several studies report exposure of humans to parabens in Western countries, little is known about the exposure of humans to parabens in Asian countries. In this study, we determined concentrations of six parabens in spot urine samples collected from nine countries and estimated daily intakes (DI) and potential health risks of parabens. Ethyl-paraben, methyl-paraben, and propyl-paraben were detected frequently at 100, 98.0, and 80.3%, respectively, with representative median concentrations of 0.68, 7.02, and 1.21 ng/mL, respectively, for all nine countries. Urine samples from females (total median concentration: 32.3 ng/mL) contained significantly higher concentrations of parabens than those from males (5.46 ng/mL). Urine samples from Korea (total median paraben concentration: 227 ng/mL) had the highest concentrations, which were one to two orders of magnitude higher than those found in other countries (3.67–29.1 ng/mL). The estimated DI of parabens (on the basis of concentrations measured in urine) varied widely, and several samples had propyl-paraben exposures above the acceptable DI. Our results suggest that paraben exposure is ubiquitous in Asian countries, and further assessment of potential health risk of these chemicals is needed.

**TP045 PBDE, PCB and OCP concentration in breast milk from three Colombian cities (Bogota, Cartagena and Medellin)**

*A.C. Torres Moreno, University of Cartagena / Facultad de Ciencias Exactas y Naturales; B. Johnson-Restrepo, L. Puente, K. Mejia-Grau, University of Cartagena / Chemistry and the Environment Group / School of Exact and Natural Sciences; G. Codling, Masaryk University / RECETOX; A. Villa, Universidad de Antioquia / Chemical Engineering Department, Faculty of Engineering, Universidad de Antioquia, Medellín; O. Rios-Marquez, Universidad de Antioquia; L. Patequiva-Chauta, M. Cobo, Universidad de La Sabana*

Concentrations of seven congeners of polybrominated diphenyl ethers (PBDEs) were reported for first time from Colombia in breast milk (BDE-28, BDE-47, BDE-99, BDE-100, BDE-153, BDE-154 and BDE-183). Thirty-seven polychlorinated biphenyls (PCBs) and fourteen organochlorine pesticides (OCP) were also analyzed in 60 human breast milk samples from volunteering mothers collected in 2015 in three important cities from Colombia. Most of the investigated PBDE congeners were detectable in the breast milk, ranging in concentrations from 0.13 to 0.78 $ng.g^{-1}$ lipid wt. BDE-47 congener had the highest concentration among the samples. Overall mean concentrations of OCP oscillated between 0.043 to 4,709,478 $ng.g^{-1}$ lipid wt. Endosulfan II was greatest concentrations among OCPs found in the matrix analyzed. On average, Cartagena was the city with the highest concentration of PBDEs 0.894 $ng.g^{-1}$ lipid wt, followed by Bogota 0,353 $ng.g^{-1}$ lipid wt and Medellin 0,338 $ng.g^{-1}$ lipid wt. Overall mean concentrations of pesticides in the cities was strongly correlated with the mean of PBDEs. OPC concentrations, on overall were 54,0631 $ng.g^{-1}$ lipid wt for Cartagena, 364,038 $ng.g^{-1}$ lipid wt and 247,742 $ng.g^{-1}$ lipid wt for Bogota and Medellin respectively. This results could be related to the city location and diet. Cartagena is the only city located on the Caribbean Sea, for instance the population consume fish more often than the population of Medellin and Bogota.

**TP046 Determination of Carbazole and Halogenated Carbazoles in Human Blood Samples using GC-MS/MS**

*J. She, Environmental Health Lab / CA Department of Public Health*

Carbazole and halogenated carbazoles have been widely detected and reported throughout the environment in soil, river deposits, and lake sediments. Human exposure to these compounds may occur through food, water, and air; bioaccumulation in the body might be evaluated by measuring the levels in blood. This paper reports the method development and validation for the analysis of carbazole and 11 halogenated carbazoles in human blood samples. A small sample size of 100 microliters of human blood or serum was employed for the analysis. The samples were prepared through salting-out liquid-liquid extraction (LLE) by using ethyl acetate/hexane (1:4, v/v) as the extraction solvent and aqueous $MgSO_4$ (38.5 wt%) as the salting-out regent, respectively. The extracts were then concentrated to near dryness under nitrogen flow, and re-dissolved in toluene. Sample analysis was performed on gas-chromatography (GC) coupled with tandem mass spectrometer (MS/MS) in an electron impact mode. The developed method has been validated and demonstrated low detection limits in the range of 0.02 – 0.27 ng/mL. The intra-day accuracy ranged from 81.2% to 125%, and the inter-day accuracy from 91.0% to 117%. The intra- and inter-day precisions, calculated by relative standard deviation (RSD), were in the ranges of 1.0–16.0% and 1.8–16.4%, respectively. The developed method was applied to the analysis of 50 human serum samples collected from pregnancy women in Southern California in 2012 – 2013. Low concentration of carbazole (below quantitation limit) was measured in 18 samples, while none of the halogenated carbazoles was detected in any of the samples.

**TP047 Using high-resolution gas and liquid chromatography to determine anthropogenic chemical exposure in youths of the Czech Republic**

*G. Codling, V.J. Schacht, K. Booij, PaSOC; A. Ionas, A. Miralles-Marco, J. Klanova, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment*

Human exposure to chemical contaminants has been a topic receiving greater interest over the last decade with projects such as NHANES in the United States and the HBM4EU in Europe. Both these and many other studies aim to determine a wide range of human contaminants. However, every year hundreds of new compounds enter the market and thus the number of compounds we are exposed to is growing. High-resolution mass spectrometry (HRMS) is becoming more and more affordable as a tool for accurate mass determination of contaminants. Full scan acquisition by HRMS provides detailed information on a wide range of compounds while potentially less sensitive than target MS the wealth of compounds determined is far superior. By using both GC and LC HRMS in various ionization modes, it is possible to identify a massive amount of information on chemical exposure. The aim of this project is to provide quantitative information on exposure of 200 youth samples (< 18 years of age) along with suspect and non-target statistical analysis. To do this a standard mixture of >800 compounds of interest including PFAS, PCBs, flame-retardants, personal care products, plasticizers and drugs was produced. From this mixture LC and GC calibration solutions were made for quantification. Two hundred serum samples of children were used in this study; they were collected by the University Hospital for oncology screening and remaining material released to this project with ethical approval from the University Ethics committee. This study does not aim to provide insights into specific cancers but rather to indicate the overall exposure of youths in the Czech Republic. A simple extraction technique to minimize compound loss was developed with 60-70% recovery of most compounds. Samples were extracted and ran on GC-Orbitrap MS in EI and NCI and by LC-Orbitrap Fusion in ESI positive and negative. The mass range used on both instruments was 70-1000amu. For the LC fusion, its dual detectors allowed for low resolution MS2 on target compounds while DIA on the top 10 most abundant ions was used for unknowns. In GC-EI-Orbitrap some 200 compounds were determined in samples >LOD while non-target detection of compounds using various deconvolution methods indicated that 1000s of additional compounds were present. In LC-Orbitrap, many 100s of compounds were also identified with many more unknowns. Suspect screening of compounds by both LC and GC indicate many compounds for further investigation.

**TP048 First measurements of the urban chemical exposome in a mega city**

*C.A. Manzano, Universidad de Chile / Department of Chemistry; E. Hoh, N. Dodder, San Diego State University / Graduate School of Public Health; R. Morales, Universidad de Chile / Department of Chemistry*

The chemical exposome is a comprehensive description of the chemicals to which one person is exposed from conception onward and could be the chemical equivalent of the environmental microbiome. This project aims to explore the urban chemical exposome of people living in a city of over 7 million people (Santiago, Chile). Samples (vapor phase atmospheric samples) were collected using personal passive samplers (ready-to-use silicon wristbands from My Exposome Inc.) and analyzed using GCxGC/ToF-MS (Pegasus 4D from LECO) with target and nontarget techniques. Volunteers for sampling were recruited from local high school institutions located in three areas of the Santiago Metropolitan Region with different socioeconomic characteristics, according to the latest population census, and at more than 15 km from each other. Volunteers (5 from each high school selected) were students living within 3 km of the institution, that walked to school and back everyday, and that did not leave their neighborhood during the exposure week. Silicon wristbands were deployed during a full workweek (Monday to Friday) during summer and winter, and later extracted using a simplified method with ethyl acetate in an orbital shaker. Extracts were concentrated to 1 mL and analyzed directly in the GCxGC/ToF-MS without further processing. More tan 800 chromatographic features were detected in all silicon wristbands within a group (neighborhood), and included personal care products, polycyclic aromatics, pesticides, insecticides and others (according to their MS and NIST library hit). However, due to the lack of enough standards, only ~30 compounds were confirmed with authentic standards (retention times and MS). The resulting compounds were classified into groups based on their uses (according to the PubChem database online), and its distribution showed seasonal and spatial variations that could be attributed to lifestyle differences. The results will be used to create the first database of vapor phase organic compounds to describe a city or neighborhood ("fingerprint"). This effort will be replicated in other cities to compare the results.

**TP049 Artificial turf: Volatile and semi-volatile chemical movement and development of silicone wristband partitioning coefficients**

*C. Donald, R. Scott, G. Wilson, P. Hoffman, K.A. Anderson, Oregon State University / Environmental and Molecular Toxicology*

This work provides the first quantitative measure of in situ flux of semi-volatile contaminants on artificial turf fields. Passive samplers were used to identify gas-phase PAHs and OPAHs not previously reported associated with artificial turf. Utilizing a broad and targeted screen, we assess both artificial turf and from crumb rubber for 1,529 chemicals, including several with known health effects including benzo[c]fluorene. We also report the presence of 25 chemicals that have not yet been reported in artificial turf literature, including some with known effects on human health. This is the first report of bioavailable gas-phase PAH and OPAH concentrations on an outdoor field, to date gas-phase concentrations have only been reported from indoor facilities. Turf air and air were highly correlated at all three sites, and particularly at the recently-installed indoor site. Finally, thermal extraction and silicone passive samplers are highly suitable for larger-scale sampling campaigns that aim for less solvent and sample processing. We demonstrate for the first time that silicone passive samplers can be used to quantify volatile and semi-volatile organic chemicals from artificial turf. Co-deploying silicone passive samplers and conventional low density polyethylene, we develop partitioning coefficients that can be used for silicone passive air sampling environmental assessment.

**TP050 Acute Cardiovascular Effects of Smoke Inhalation in Firefighters**

*J. Nelson, University of Alabama at Birmingham / Environmental Health Science; M. Chalbot, College of New Rochelle / Environmental Health Sciences; I. Kavouras, CUNY Graduate School of Public Health and Health Studies / Department of Environmental, Occupational, and Geospatial Health Sciences*

Firefighters comprise the largest group of public safety employees with more than 1,000,000 career and volunteer firefighters in the United States. Among this occupation, cancer and cardiopulmonary diseases account for more than half of work-related deaths, with smoke inhalation being the primary risk factor. Even though biomass smoke inhalation is shown to increase disease incidence, the comprehensive impacts of exposure and the components(s) responsible for disease outcomes are not well understood. During active fires, firefighters often work within the smoke plume to continuously manipulate the fire front. Respiratory protection is rarely practiced due to the weight and limited air capacity of most respirators. As a result of their proximity to active fires and lack of respiratory protection, wildland firefighters are exposed to hazardous pollutants such as aerosolized carcinogenic chemicals (e.g. polycyclic aromatic hydrocarbons (PAHs), formaldehyde, and benzene) as well as other irritants and toxins (acrolein, PM, and carbon monoxide). According to IARC, firefighting exposures are classified as possibly carcinogenic to humans (Group 2B). Smoke particles may trigger systemic inflammation and oxidative stress through formation of reactive oxygen species (ROS). ROS may induce endothelial dysfunction in arteries, leading to physiological function deterioration. The characterization of smoke exposures with biological (or clinical) monitoring is limited due to the inherent hazards of interfering with firefighting tasks in an active wildfire environment. This project utilized the strengths of in situ occupational exposure monitoring and health assessments to determine the effects of biomass smoke's PM on cardiovascular function impairment in wildland firefighters. We utilized continuous lightweight particle counting monitors to determine personal exposures to PM. Changes in cardiovascular function were measured continuously by heart monitors and ambulatory blood pressure monitors. During this study, firefighters were exposed to PM ranging from 0.03 to 10.3 mg/m$^3$ over periods of 4 to 7 hours. We found cross-shift increases in heart rate and decreases in blood pressure indicating acute cardiovascular effects after biomass smoke inhalation.

**TP051 Chemical characterization and potential risks from air emissions at hydraulic fracturing operations in Alberta**

*M.L. Olsgard, G. Goss, University of Alberta / Biological Sciences; J. Olfert, University of Alberta / Engineering*

Hydraulic fracturing fluids have been successfully used for many years to increase well-site productivity in tight oil and gas formations. Once the reserve is sufficiently fractured to release the oil or gas from the geological formation the fracturing fluids must be returned or "flowback" to surface. At surface the liquid and gaseous components are separated, liquids are stored while gases and aerosols are combusted through flaring and released to the ambient environment. In Alberta, the annual average volume of gas flared to the environment from horizontal multistage fractured oil and gas wells is 167.6 million m$^3$. To date hydraulic fracturing (HF)technology has been used at more than 180,000 oil and gas wells in Alberta. As the intensity of hydraulically fractured oil and gas well development increased, so too did concerns of potential adverse health effects in nearby residents and livestock. The anxiety and anger over noted health effects in residents in rural Alberta has not ceased. Provincial government has also expressed concerns about the possible deterioration of air quality in proximity to HF wells and adverse health effects in exposed populations.The provincial regulator has published 2 separate reports of recurrent human health complaints to identify the cause of resident's concerns. Neither of these reports could address the risks from air emissions at HF operations as pre and post flare emission streams had not been characterized. The data gap forced the provincial regulators of health and the environment to initiate studies to characterize both the pre- flare stream and a partial post combustion stream. For the first time chemical characterization including inorganic (cations, anions, radon, metals) and organic (chlorinated and brominated additives, VOCs, PAHs) gases and aerosols in the pre and post flare streams at hydraulic fracturing operations in Alberta will be presented. The data will be presented in a risk-based context focusing on potential linkages to reported health effects of residents of Alberta.

**TP052 Molecular profiling of electronic cigarette liquids and vapors by NMR spectroscopy**

*O. Dada, University of Alabama at Birmingham / Environmental Health Science; M. Chalbot, College of New Rochelle / Environmental Health Sciences; P. Demokritou, Harvard TH Chan School of Public Health / Department of Environmental Health; I. Kavouras, CUNY Graduate School of Public Health and Health Studies / Department of Environmental, Occupational, and Geospatial Health Sciences*

Electronic cigarettes (e-cigs) have been designed to mimic conventional cigarette and deliver nicotine vapors (e-vapors) without the harmful tobacco byproducts such as tar and polycyclic aromatic hydrocarbons (PAHs). In addition to nicotine, e-cig liquids (e-liquid) contain propylene glycol, glycerin, water and unidentified chemicals used as flavors and preservatives. Some of them are classified as "generally regards as safe" chemicals as food additives; however, their effects when inhaled are unknown. Moreover, e-vapors may contain hazardous and carcinogenic byproducts formed during heating. The variability in e-liquids composition, conjointly with inconsistent user patterns and conditions, may trigger adverse exposure conditions to e-vapors of users and secondhand groups. The objective of the study is to determine the molecular composition of e-vapors and relate it to the e-liquid chemical fingerprinting and e-vapor generation conditions. To achieve this, a rapid non-destructive methodology has been developed for the spectral recognition of the major components (i.e. nicotine, propylene glycol and glycerin) as well as flavors and byproducts formed during e-vapors generation. The limit of detection, quantification, accuracy, precision, bias and uncertainty were determined using authenticated standards. E-vapors from 43 e-liquids were generated by a single port e-cigarette exposure system using the puff protocol (4 sec duration puffs every 30sec with a total puff volume of 55ml). Particle number and size distribution were monitored by continuous analyzers. E-vapors were collected of filter media and analyzed by 1D $^1$H and 2D $^1$H-$^1$H and $^1$H-$^{13}$C NMR spectroscopy. E-liquids spectra were dominated by propylene glycol and glycerin resonances; however, resonances in the aromatice and carbonyl regions were also observed. Menthol and vanillin were identified in most of the e-liquids. Elevated particle number concentrations were associated with e-vapors with most of them in the accumulation mode (with diameter from 0.5-1 µm). In addition to propylene glycol and glycerin, nicotine, benzene and toluene were also detected in the range of 100–38,000 ppbv/puff. The findings of this study demonstrate the potential for inhalation of large quantities of chemicals with unknown toxicological responses in the respiratory tract and the generation of known carcinogens, supporting the immediate need to better characterize the composition and toxicological profiles of e-vapors.

**TP053 Size distribution and clothing-air partitioning of polycyclic aromatic hydrocarbons generated by barbecue**

*J. Lao, Jinan University*

Barbecue (BBQ) is one of the most popular cooking activities with charcoal worldwide and may produce abundantpolycyclic aromatic hydrocarbons (PAHs) and particulate matter. Size distribution and clothing-air partitioning ofparticle-bound PAHs are significant for assessing potential health hazards to humans due to exposure to BBQ fumes, but have not been examined adequately. To address this issue, particle and gaseous samples were collected at 2-m and 10-m distances from a cluster of four BBQ stoves. Personal samplers and cotton clothes were carried by each participant sitting around the BBQ stoves. Particle-bound PAHs (especially 4−6 rings) derived from BBQ fumes were mostly affiliated with fine particles in the size range of 0.18−1.8 µm. High molecular-weight PAHs were mostly unimodal peakingin fine particles and consequently had small geometric mean diameters and standard deviations. Source diagnostics indicated that particle-bound PAHs in BBQ fumes were generated primarily by combustion of charcoal, fat content in food, and oil. The influences of BBQ fumes on the occurrence of particle-bound PAHs decreased with increasing distance from BBQ stoves, due to increased impacts of ambient sources, especially by petrogenic sources and to a lesser extent by wind speed and direction. The present study also demonstrated that Ant/(Ant+Phe) may be a good indicator of distance variability from emission sources. Octanol-air and clothing-air partition coefficients of PAHs obtained from personal air samples were significantlycorrelated to each other. High molecular-weight PAHs had higher area-normalized clothing-air partition coefficients in cotton clothes, i.e., cotton fabrics may be a significant reservoir of higher molecular-weight PAHs.

**TP054 Occupational paint exposure: Implication on blood total antioxidant capacity and antioxidant enzymes activity in Nigeria**

*I.C. Ikaraoha, Imo State University Owerri / Chemical Pathology Unit / Dept. of Medical Laboratory Science; C. Unadike, Imo State University Owerri / Medical Laboratory Science; U.P. Ukaigwe, Imo State University Owerri / Chemical Pathology Unit / Dept of Medical Laboratory Science; N.C. Mbadiwe, University of Nigeria Teaching Hospital Enugu / Medicine; C.N. Nwadike, Imo State University Owerri / Medical Laboratory Science; J. Dike-Ndudim, Imo State University Owerri / Department of Medical Laboratory Science; H.M. Okorie, Imo State University Owerri / Department of Medical Laboratory Science*

Numerous harmful complex mixtures of chemicals and heavy metals; benzene, plasticizers, chromium, Cadmium and lead oxides have been reduced or substituted in paint in some countries, although they are still used in some developing countries like Nigeria. Evidence is rising continually concerning the adverse health effects of exposure to toxic chemicals in paint, yet it has not been adequately addressed in Nigeria. The aim of this study is to determine the effect of occupational exposure to paint on blood level of some antioxidant enzymes and Total Antioxidant Capacity (TAC), as an assessment of health risk. By random sampling, volunteers consisting of thirty (30) male painters aged between 20 to 50 years and 30 age-matched male controls were selected for the study. Five (5) ml of venous blood were collected from all participants for determination of serum Antioxidant enzymes; superoxide dismutase (SOD), catalase and glutathione peroxidase activities and also Total Antioxidant Capacity (TAC) using ELIZA techniques. SOD, catalase, Glutathione peroxidase and TAC levels in exposed group were significantly decreased($p=0.000$ in each case) in Cement Workers on comparison with control group. Comparison of the antioxidant enzymes in paint workers with < 5 years' exposure versus paint workers with ≥5 years' exposure shows no statistical difference in serum SOD, glutathione peroxidase, and TAC ($p=0.095$, $p=0.945$ and $p=0.837$ respectively). But there was significant increase in serum catalase level of paint workers with >5years exposure compared to those with < 5years exposure ($p=0.038$). There was no significant correlation of serum TAC with SOD, Catalase and Glutathione Peroxidase in Paint Workers ($r=0.059$, $P=0.784$; $r=0.077$, $P=0.720$ and $r=0.051$, $P=0.812$ respectively). It appears that occupational exposure to complex mixture of solvents and heavy metals contained in paint may lead to generation of free radicals, increase in oxidative stress among the paint workers, and thus may contribute to the observed decreases in antioxidant enzymes and TAC activities, thereby predisposing them to adverse health effects

**TP055 The Unexpected Way Alligators Can Harm you**

*E. Madonick, Brooks Applied Labs*

Industrial polluters play a major role in the effects of ecotoxicity translated to apex predators. Bioaccumulation of harmful metals up the food chain is an alarming human-health concern, particularly in at-risk populations such as young children and women of child-bearing age. Alligator meat has been touted as a healthy protein alternative to beef, chicken, and pork and is rapidly becoming more popular with gourmet options featured in restaurants and recipes online. Additionally, there is a large underrepresented population of subsistence hunters in the Southern United States that rely on alligator meat as the primary source of protein in their diets. In this study, alligator meat samples were collected from six different regions in Mississippi and Louisiana. Mercury, monomethylmercury, and additional elements of potential concern were evaluated with regards to physical and spatial attributes.

**TP056 Persistent and Toxic Chemical Pollutants in Fish Consumed by Asians in Chicago**

*Q. Tang, Zhejiang University / College of Environmental and Resource Sciences; A. Li, University of Illinois at Chicago / School of Public Health; K.E. Kearney, K.L. Nagy, University of Illinois at Chicago / Department of Earth and Enviromental Science; J. Zhang, M.E. Turyk, S. Buchanan, University of Illinois at Chicago / School of Public Health*

Fish in contaminated waterways contain persistent and bioaccumulative toxicants such as mercury (Hg), polychlorinated biphenyls (PCBs), organochlorine pesticides (OCPs), polybrominated diphenyl ethers (PBDEs) and other halogenated flame retardants (XFRs). Ingesting these contaminants via fish consumption increases the risk of cancer, cardiovascular disease, prenatal developmental abnormalities, and other health problems. Compared with other racial/ethnic groups in the U.S., Asians consume seafood more frequently. However, there is little information about how culturally specific fish consumption contributes to exposure to these toxins. As part of a large-scale assessment and intervention project among the Asian population in Chicago, we obtained 103 seafood samples from local vendors (supermarkets, fish markets, Asian markets) and analyzed each sample for 66 PCBs, 17 OCPs (3 DDT related compounds, 4 HCHs, and 10 others), 8 PBDEs, and 9 other XFRs with the use of gas chromatography coupled with triple quadrupole mass spectrometry (GC/QQQMS). Total Hg was measured by a DMA-80 direct mercury analyzer. The samples covered 21 different types of fish and foodstuff including unusual fish species such as eel and fish cakes, and were selected based on a survey on fish consumption among Chinese, Korean and Vietnamese communities in Chicago. Among organic chemical groups, the rank order of concentration in all samples was $S_{66}$PCBs > $S_{17}$OCPs > $S_{8}$PBDEs > $S_{9}$XFRs. Spearman correlations among analyte groups were statistically significant at 95% confidence level, with the exceptions of those between $S_{4}$HCHs and $S_{66}$PCBs, $S_{8}$PBDEs, or $S_{9}$XFRs, and between Hg and $S_{17}$OCPs. Among the individual organic analytes, DDT was the highest in both median (0.7 ng/g wet weight) and mean (2.1 ng/g ww) concentrations, and cis-permethrin, a currently available insecticide, had the highest detection frequency (95%). The rank of the sample types varied by chemical groups. Fish with highest mean Hg (> 1 mg/kg) were bluefish and pike. The mean $S_{66}$PCBs was highest in pike and bluefish (>100 ng/g ww) followed by pollock and mackerel (>40 ng/g ww); these fish species were also more contaminated by flame retardants than others. The highest $S_{17}$OCPs (>40 ng/g ww) were observed in pompano and yellow croaker. Overall, octopus, shrimp, and tilapia were the least contaminated. Results of this analysis will inform future exposure assessments and the development of intervention strategies.

**TP057 Mixed-Organic/Inorganic-Chemical Exposure in USA Point-of-Use Drinking Water**

*P.M. Bradley, USGS / South Atlantic Water Science Center; D.W. Kolpin, USGS / Central Midwest Water Science Center; K. Romanok, USGS; K.L. Smalling, USGS / NJ Water Science Center*

Drinking-water from 25 sites (13 home, 12 workplace) in 11 US states was assessed at the point of use (tapwater) for 482 organics and 19 inorganics, with 6 home samples from untreated, self-supply. Seventy-one organics were detected in at least one tapwater sample, some exceeding drinking water Maximum Contaminant Level Goals. Two inorganics were frequently detected at concentrations exceeding drinking water Maximum Contaminant Level Goals. A multiple lines of evidence approach was used to evaluate potential human-health concerns of detected tapwater chemicals. These results document the widespread potential in the US for human exposure to a variety of previously uncharacterized contaminant mixtures in tapwater.

**TP058 Identifying agricultural pesticides from tap water and household dust samples in Knights Landing utilizing GC-qTOF-MS and LC-qTOF-MS**

*G. Lebrec, University of California, Davis / Civil and Environmental Engineering; J.S. Kelty, UC Davis; L. Van Winkle, UC Davis / Center for Health and the Environment; L. Wong, UC Davis; T.M. Young, University of California, Davis / Civil and Environmental Engineering*

Pesticide usage in Knights Landing, CA is a community health concern based on close proximity between residences and surrounding agriculture, particularly due to drift from aerial spraying.Based on Pesticides Information Portal data, an annual average of 997,540 pounds of pesticideactive ingredients were sprayed between 2011 and 2015 in the zip codes surrounding Knights Landing. The aim of this project is to better understand the significance of aerial spraying withexposure in nearby communities. Contamination of well-sourced tap water and accumulation ofpesticides in indoor dust are theorized to be major sources of household sources of exposure.Detection of pesticides in tap water from private wells would suggest leaching to the groundwater, while detection in household surface dust would suggest wind travel or occupant delivery. Current monitoring of pesticides in tap water or household dust is limited to the small public water system in Knights Landing. Using both targeted and suspect GC-qTOF-MS and LC-qTOF-MS analysis we are able to perform a holistic chemical analysis of these samples. The target analysis will consist of fourteen pesticides including Diuron, Bifenthrin, and Chlorothalonil. We will also perform suspect analysis by screening the data through a personal compound database library (PCDL) containing spectral information for over 1,600 pesticides and their degradation products. Five tap water and five household dust samples were collected fromKnights Landing homes for this study. This poster outlines the methods and workflow used for water and dust extractions, as well as for both targeted and suspect data analysis. This study addsto our understanding of the residential exposure to pesticides in intensive agricultural areas of California. Supported by P30 ES023513 and T32 HL007013

**TP059 Characterizing Azobenzene Disperse Dyes in Indoor Environments**

*K. Overdahl, Duke University; A.L. Phillips, S. Hammel, K. Hoffman, H.M. Stapleton, Duke University / Nicholas School of the Environment; L. Ferguson, Duke University / Nicholas School of the Environment / Department of Civil and Environmental Engineering*

Disperse dyes are a class of substituted anthroquinone- or azobenzene-based dyes used to color synthetic fabrics such as polyester, nylon, and acrylic. Many of the dyes are chlorinated or brominated and account for roughly 70% of the 9.9 million tons of industrial dye colorants used annually. Azobenzene dyes are well-characterized as electrophilic mutagens and contact allergens in clothing and in the aquatic environment, but little is known about occurrences and health implications of these dyes in the indoor environment. Here, we report on the concentrations of several azobenzene dyes in house dust samples collected from 190 homes in the Toddlers Exposure to SVOCs in Indoor Environments (TESIE) study in central North Carolina (2014-2016). Five representative azobenzene dyes and two transformation products were quantified in the TESIE dust samples to assess children's exposure to dyes in the indoor environment. House dust samples were collected for each study participant's household using standardized protocols. All samples were analyzed for Disperse Blue 373, Disperse Orange 25, Disperse Orange 37, Disperse Orange 61, and Disperse Violet 93, and for the transformation products (TPs) 2,6-dibromo-4-nitroaniline and 2-bromo-4,6-dinitroaniline. Dyes were analyzed via HPLC-ESI-HRMS/MS and quantified via HPLC-APCI-MS/MS. One or more dyes were detected in 92% of house dust samples. Quantitative measurements revealed that these dyes and TPs are present at levels up to 10 µg/g in house dust. Geometric means ranged from 50 ng/g to 254 ng/g house dust, with Disperse Blue 60 having the highest concentration overall. In addition, several brominated dyes were found at levels known to exhibit mutagenicity and concentrations were similar to ranges reported for brominated flame retardants. These results suggest that children's exposures to disperse dyes in house dust is common, and warrants further detailed study and characterization. Future work in our laboratories will examine the potential for disperse dyes to act as respiratory allergens at environmentally relevant concentrations.

**TP060 Azoxystrobin Exposure in the Indoor Environment: Is Drywall a Source?**

*H.M. Stapleton, E. Cooper, J. Rushing, K. Hoffman, A.L. Phillips, S. Hammel, Duke University / Nicholas School of the Environment; M. Zylka, University of North Carolina, Chapel Hill*

Azoxystrobin is a fungicide that belongs to the class of chemicals known as strobilurins, which were originally derived from the fungus *Strobilurus tenacellus*. Today the strobilurin pesticides are a high production volume fungicide used primarily in fruits and vegetables. However, a recent study raised concerns about the potential for these chemicals to cause neurotoxicity. Interestingly, azoxystrobin now has a patent for use in wallboards (i.e. drywall) to prevent mold growth, but it's unclear whether or not these fungicides would migrate into indoor environments. The purpose of this study was to determine if azoxystrobin could be detected in new drywall samples, and whether the strobilurins would be detected in samples of house dust. To support this study we collected 10 dry wall samples intentionally marketed for use in bathrooms to inhibit mold, and analyzed 191 house dust samples collected through a children's health study in central North Carolina in 2014-2016. The drywall and house dust samples were extracted and analyzed for four strobilurin pesticides, including azoxystrobin, pyraclostrobin, trifloxystrobin and fluoxastrobin using liquid chromatography tandem mass spectrometry. Detection frequencies in house dust for the four fungicides ranged from 36 – 93%. Azoxystrobin was detected most frequently and at the highest concentrations with a geometric mean of 3.4 ng/g and a maximum concentration of 10,590 ng/g. The geometric means and ranges for pyraclostrobin, fluoxastrobin and trifloxystrobin were 0.51 (< MDL – 35.6), 0.21 (< MDL- 40.7) and 0.05 (< MDL -2.6 ) ng/g, respectively. Azoxystrobin was also detected in newly purchased purple wallboard samples at concentrations near 1% by weight. Ongoing analyses are examining the variability in dust concentrations for azoxystrobin based on the age of the home, and the presence of this type of wallboard in the home. These results suggest that fungicides present in wallboard may be migrating to the indoor environment, leading to exposure in the residences that would constitute a separate exposure pathway independent of dietary exposures.

**TP061 Human Exposure to Phthalate Esters (PAEs) in Social Housing Apartments**

*Y. Wan, University of Toronto, Scarborough / Department of Physical and Environmental Sciences; M.L. Diamond, University of Toronto / Department of Earth Sciences; J.A. Siegel, University of Toronto / Civil and Mineral Engineering*

Phthalate esters, widely used as plasticizers and additives in building materials and consumer products, have been found to cause a range of adverse health effects at ambient levels. Many indoor sampling studies have focused on homes from mid-to-high-socio-economic status (SES) occupants. Residents of low-income social housing are vulnerable to health effects from exposure to indoor air pollution and yet have received much less attention. This study documented concentrations of eight phthalates (DEP, DiBP, DnBP, BzBP, DEHP, DnOP, DiNP and DiDP) in indoor air with the larger goal of assessing indoor exposure in lower income social housing. Silicone rubber (polydimethylsiloxane or PDMS) passive air samplers were deployed for one week in 71 units in 7 multi-unit social housing buildings located in Toronto, Canada, during the late spring of 2017. Three types of units were sampled: bachelor, senior and family apartments. Sixty-five of the 71 PDMS samplers deployed were recovered for analysis on a GC-MS in EI mode. Chemical mass collected by the samplers was converted to air concentrations. All eight phthalates were detected in all the PDMS samples from 65 units. DEP (found in fragranced products) was the dominate phthalate in indoor air with a geometric mean concentration of 2,160 ng/m$^3$, followed by DnOP (1,440 ng/m$^3$) and DiBP (1,200 ng/m$^3$), which are mainly used as plasticizers. Concentrations of DnBP, DnOP and DiNP in senior and family units were significantly ($p < 0.05$) higher than those in bachelor units. In general, residents in social housing units experienced two to 16 times higher air concentrations of phthalates than those of predominantly detached and semi-detached houses in Toronto (presumably occupied by occupants with higher SES and with lower occupant densities).

**TP062 Estimating human exposure to di(2-ethylhexyl)phthalate in indoor environment using an indoor exposure model at different temperature**

*D. Kim, J. Kwon, Korea University / Division of Environmental Science and Ecological Engineering*

Although di(2-ethylhexyl)phthalate (DEHP) has adverse health effects on humans, it is still widely used as a plasticizer in many polyvinyl chloride (PVC) products. Because DEHP is a semi-volatile organic chemical (SVOC), it is emitted from PVC flooring in indoor environment. Human may be exposed to DEHP via direct inhalation of gaseous DEHP or ingestion of indoor dust particles sorbing DEHP. To estimate the exposure to SVOCs, an indoor exposure model is used. To predict the concentration of SVOCs in indoor environment using a model, the emission rate is an important parameter and is related to the diffusion coefficient of SVOCs in PVC flooring material. The emission rate may change with temperature because the diffusion coefficient is temperature-dependent. Even though the room temperature does not change much, PVC floors are heated directly to warm home in Korea during winter season. To apply this home-heating conditions in Korea, the concentrations of DEHP in indoor air were estimated using an indoor exposure model at various contents and the diffusion coefficients of DEHP in PVC flooring as parameters to estimate emission rate at different temperature. The exposure model was developed using mass balance equations which account for the accumulation of DEHP in indoor environment. The migration rates of DEHP from PVC flooring to a passive sampler using polydimethylsiloxane at different temperature (20, 25, 40, and 60 °C) were measured to obtain the diffusion coefficients of DEHP in PVC flooring materials. The indoor air concentrations of DEHP at steady state were estimated 0.05, 0.25, and 0.49 µg m$^{-3}$, and the concentrations sorbed to indoor dust were 0.014, 0.069, and 0.137 $\mu g_{DEHP}\ \mu g_{dust}^{-1}$ when the contents of DEHP in PVC flooring are 1, 5, and 10 % respectively at 25 °C. The inhalation exposure and dust ingestion exposure to DEHP were estimated 0.22 and 1.22 µg kg$^{-1}$ day$^{-1}$ for one-year-old baby whose body weight is 11 kg and inhalation rate is 9.75 m$^3$ day$^{-1}$. The diffusion coefficients of DEHP in PVC flooring were measured as $2.76 \times 10^{-17}$, $6.14 \times 10^{-17}$, $4.95 \times 10^{-16}$, and $2.90 \times 10^{-15}$ cm$^2$ sec$^{-1}$ at 20, 25, 40, and 60 °C respectively. Stiff increase in diffusion coefficient in PVC flooring with temperature suggests that the emission rate of DEHP from PVC flooring would dramatically increase under the home-heating condition during the winter, leading to elevated intake rates via gas inhalation and dust ingestion.

**TP064 Triphenyl phosphate promote the development of atherosclerosis and foam cell formation**

*W. Hu, H. Ma, J. Hu, Peking University*

Triphenyl phosphate (TPHP), one of the organophosphate flame retardants (OPFRs), has been frequently detected in the environmental media and even in the blood of the general population. It has been reported that TPHP could cause various adverse effects such as endocrine disruption and obesity. In our study, we evaluated plasma lipid change and the severity of atherosclerosis based on the morphological and histological changes that occurred in a well establised mode of atherosclerosis (ApoE-/- mice). We treated the mice with 10 mg/kg bw and 40 mg/kg bw TPHP for 13 weeks. Results showed that 40 mg\kg bw TPHP exposure can significantly increase the level of total cholesterol and triglycerides in serum. TPHP can significantly promote the development of atherosclerosis in mice at the dose of 10 mg\kg bw and 40 mg\kg bw. Since foam cell formation plays a central role in the development of atherosclerosis, we determined the foam cell formation induced by TPHP, and found that TPHP can significantly promote the formation of foam cell in vitro. Our study show that TPHP can promote foam cell formation and atherosclerosis, and call for further study of the toxicological effects of TPHP on human health.

**TP065 Asthma risk associated with the US 2012 heatwave: A local health department prespective**

*L. Figgs, Douglas County Health Department / Environmental Health*

*Background*: Public concern about global climate change is forcing local public health agencies to assess how climate change might impact local disease risk.*Objective:* Estimate local asthma diagnosis risk associated with the 2012 heatwave.*Methods:* This is a retrospective, observational, epidemiologic investigation using a case-control study design. Subjects are selected from Douglas County NE hospital emergency department (ED) admissions in 2011 and 2012. Risk is estimated by conditional logistic regression. *Results*: Overall, asthma ED diagnosis odds were 1.23 (95% CI; 0.96-1.57) times higher in 2012 compared to the same 2011 calendar period. Asthma ED diagnosis odds were 3.37 (95%CI=2.27-4-17) times higher among subjects < 19 years old compared to subjects ≥ 19 years old, and 3.25 (95%CI=2.63-4.02) times higher among African-Americans than non-African-Americans. Absolute humidity was inversely related to asthma diagnosis risk ( 2 = 16.6; p< 0.001). *Conclusion:* Asthma diagnosis risk was elevated in Douglas County's 2012 ED.

**TP066 Effect of aqueous extract of cocos nucifera oil on sex hormones and some markers of oxidative stress in drug-induced testicular toxicity in rats**

*C.N. Nwadike, H.U. Nwanjo, S. Uchendu, Imo State University Owerri / Department of Medical Laboratory Science; A. Evekwe, Imo State University Owerri / Medical Biochemistry; K.K. Onyejekwe, Imo State University Owerri / Biochemestry; I.C. Ikaraoha, Imo State University Owerri / Chemical Pathology Unit / Dept. of Medical Laboratory Science*

Human spermatozoa, as recorded, appears to suffer from oxidative stress with impact on the normality of their functions and the integrity of their nuclear and mitochondria DNA. Objective: This study was aimed at investigating the effect of Virgin coconut oil (VCO)on ciprofloxacin-induced testicular toxicity and oxidative stress. Method: 36 male Albino rats (weighing between150-200g) were divided randomly into four experimental groups ; group I, received 1ml of distilled water. Group 2 received 130 mg/kg B.W of ciprofloxacin. Group 3 received 130 mg/kg B.W of ciprofloxacin and 10 ml/kg B.W body weight of virgin coconut oil, 30 minutes after ciprofloxacin, while group 4 received 10ml /kg B.W of virgin coconut oil only. All animals were allowed access to normal food and water ad libitum. The administration was done orally for a period of 25days. Semen samples were collected at the end of the experiment and used for the analysis of sperm count and sperm motility. Blood samples were also collected for the determination of testosterone, FSH ,LH, superoxide dismutase activity and serum malondialdehyde by direct spectrophotometric method(for SOD and MDA) and ELISA assay( for Testosterone, FSH and LH ). Result: The results obtained shows that there were statistically significant decrease in sperm concentration , motility, serum testosterone and superoxide dismutase activity in group 2 when compared to the groups 1 and 4. Significant increase was observed in the mean levels of malondialdehyde, FSH and LH in group 2 when compared to those of groups 1 and 4 at P< 0.05. The mean levels of sperm concentration, motility, ,testosterone , and superoxide dismutase were significantly increased in group 3 when compared to those of group 2 . The serum levels of malondialdehyde, FSH and LH decreased significantly in group 3 when compared to group 2. Conclusion: Results demonstrated that Ciprofloxacin induced poor sperm characteristics, in addition to reproductive hormone imbalance in male rats. However this stress induced toxicity was eventually ameliorated by Virgin coconut oil . VCO can therefore be recommended as supplement in the management of ofloxacin induced hormonal imbalance and oxidative stress in males.

**TP067 Simultaneous analysis of seven biomarkers of oxidative damage to lipids, proteins, and DNA in urine**

*M. Martinez-Moral, NYSDOH / Wadsworth Center; K. Kannan, Wadsworth Center / New York State Department of Health / Division of Environmental Health Sciences*

The determination of oxidative stress biomarkers (OSBs) is useful for the assessment of health status, exposure to emerging contaminants and progress of diseases in humans. Whereas previous methods for the determination of OSBs in urine were focused on a single marker, in this study, we present a method for the simultaneous determination of biomarkers of oxidative damage to lipids, proteins, and DNA. 2,4-Dinitrophenylhydrazine (DNPH) derivatization followed by solid phase extraction (SPE) and high-performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS) allowed the determination of 8-hydroxy-2'-deoxyguanosine (8-OHdG), o-o'-dityrosine (diY), malondialdehyde (MDA), and four $F_2$-isoprostane isomers: 8-iso-prostaglandin$F_{2\alpha}$ (8-$PGF_{2\alpha}$), 11β-prostaglandin$F_{2\alpha}$ (11-$PGF_{2\alpha}$), 15(R)-prostaglandin$F_{2\alpha}$ (15-$PGF_{2\alpha}$), and 8-iso,15(R)-prostaglandin$F_{2\alpha}$ (8,15-$PGF_{2\alpha}$) in urine. Derivatization with DNPH and SPE were optimized to yield greater sensitivity and selectivity for the analysis of target chemicals. The limits of detection of target analytes in urine were below 30 pg $ml^{-1}$. The assay intra- and inter-day variability was below 16% of the relative standard deviation, and the recoveries of target chemicals spiked into synthetic urine were near 100%. The method was applied to the analysis of 21 real urine samples, and the analytes were found at a detection frequency of 85% for 8-$PGF_{2\alpha}$ and 15-$PGF_{2\alpha}$, 71% for 11-$PGF_{2\alpha}$, 81% for 8,15- $PGF_{2\alpha}$ and 100% for diY, 8-OHdG, and MDA. This method offers simultaneous determination of multiple OSBs of different molecular origin in urine samples selectively with high accuracy and precision.

## Environmental Stewardship and Economic Development: How We Can Accomplish Both

**TP068 Buffalo River Remediation, Restoration and Revitalization**

*R. Davis, Anchor QEA LLC / Natural Resources; R. Mohan, M. Reemts, Anchor QEA LLC*

Over 500,000 cubic yards of contaminated sediments were removed from the Buffalo River AOC as part of a Great Lake Legacy Act project. Remediation was performed as a collaboration of GLNPO, Honeywell, and USACE and involved dredging and capping adjacent to riverfront structures and shorelines and coordinating work with property owners, the Buffalo Niagara Waterkeeper and the City of Buffalo. The project also included a significant habitat restoration component that was designed to augment ongoing and planned restoration projects at adjacent sites. The combination of remediation and restoration has increased public use of the shoreline areas and waterways which are part of the Buffalo "Blueway." The Blueway is in integral part of the Buffalo Revitalization Strategic Plan to connect citizens with the shoreline and river and generate interest and investment for revitalizing riparian properties.

**TP070 Prioritizing Site Remediation and Restoration to Achieve Economic and Conservation Goals**

*S.S. Brown, The Dow Chemical Company / Environmental Remediation and Restoration*

Corporate environmental remediation managers are charged with investigating and addressing contaminant risks in order to achieve effective site remediation and liability closure quickly and cost effectively. Corporate and regulatory managers might emphasize differing priorities, but all would do well to focus early on options and opportunities for future uses for these properties. Sites in urban areas frequently provide opportunity for economic redevelopment, subject to any necessary restrictions. Redevelopment options are often prioritized in urban settings, but these sites also afford the chance to restore and protect riparian buffers and floodplains (green infrastructure) and to reconnect neighborhoods with natural resources. Redevelopment and environmental stewardship are not mutually exclusive! In cases where large corporate land holdings are located in more remote and ecologically sensitive areas, which may or may not be subject to remediation, these lands sometimes have the potential to support high-priority, regionally significant conservation objectives. Within the Environmental Remediation and Restoration Group at Dow, we have prioritized planning for future land use that provides a mix of redevelopment and green infrastructure at urban sites, and maximizes conservation value and ecological services at more remote sites. In this presentation, ongoing projects will illustrate a collaborative approach that utilizes scientific research with academic partners to address site-specific risks, and interactions with land planners and conservation partners to create future use options that maximize economic and ecological value, as appropriate for each site. Trust derived from these partnerships and mutually beneficial future use scenarios help create a project climate that can serve to expedite site remediation/restoration, closure, and subsequent transaction for redevelopment and/or conservation

**TP071 Enhancing Ecosystem Services in the Hackensack Meadowlands through Remediation and Restoration**

*R. Davis, Anchor QEA LLC / Natural Resources; S.S. Brown, The Dow Chemical Company / Environmental Remediation and Restoration*

The Hackensack Meadowlands is one of the most recognizable wetland complexes in the United States. While drastically reduced in size since the 1700s due to multiple anthropogenic impacts, the Meadowlands provides valuable ecosystem services to the region. These services include flood control and storm protection, sediment and nutrient retention and export, and ecological habitat including the Atlantic Flyway for migratory birds. Restoration of the wetland and ecosystem functions in this heavily urbanized watershed has been an agency and community goal for decades, and there are several examples of restored wetland areas throughout the Meadowlands. Restoration efforts have had to overcome challenges such as Phragmites, dams, ditched and diked tributaries, contaminated sediments, and most recently changes associated with sea level rise and major storms including Superstorm Sandy. The Meadowlands are also home to several active contaminated sediment sites. Remedial investigations and feasibility studies of these sites are in progress or planned. Management of these sites provides an opportunity to evaluate and plan remediation in the context of the larger watershed-scale initiatives to reduce risk, restore ecosystem functions, and provide resiliency to counter sea level rise and climate change. This presentation will provide examples from lacustrine, riverine and estuarine systems where restoration has been integrated with sediment remediation to reduce risks to ecological and human health and enhance ecosystem services. Examples on how this approach can be integrated with other coastal resiliency initiatives (e.g., Rebuild by Design) will also be discussed.

**TP072 Novel Analysis of Pollution Prevention Data in New Jersey**

*D.R. Millemann, R. Mueller, N. Procopio, New Jersey Department of Environmental Protection / Division of Science, Research & Environmental Health*

Pollution prevention (P2) planning is a regulatory tool used to promote economic benefits for manufacturing facilities, as well as environmental benefits for the public. Facilities are required to report chemical data annually to satisfy regulatory requirements, and researchers and policy makers use these data to assess the success of the regulation and design future regulatory programs. P2 methodologies are well established; however, analysis of P2 data can be inconsistent and difficult to interpret due to the variability in reporting requirements from year to year. The New Jersey Department of Environmental Protection recently reviewed its P2 data to establish trends in the reduction of toxic compounds within the state. Facility data were analyzed for 1,009 facilities which includes 5,601 chemical processes. Non-product output (NPO), which includes on-site releases and off-site material transfers, was reported at 498 million pounds in 1996 and was reduced by 71.9% to 140 million pounds in 2009. The use (USE; total material consumed, shipped, and NPO) of reported chemicals decreased by 54.4% from a state maximum of 31.6 billion pounds in 1999 to 14.4 billion pounds in 2015. These values are subject to several changes in reporting requirements over time, and thus may not be representative of true losses (and/or gains) over the evaluation period. A novel approach was developed to determine reductions at a process level by evaluating the longevity and reductions during the life-cycle of processes. This approach more directly demonstrates the benefits of P2 planning while eliminating the variability introduced by inconsistencies in reporting requirements. During the first 10 years of P2 planning, USE decreased by 21.7% from the maximum in Year 2 of 25.9 billion pounds to 20.3 billion pounds in Year 10 for processes that existed for at least 10 years. For this same cohort, NPO decreased by 59.7% from 485 million pounds to 195 million pounds during 10 years of planning. Since its inception in 1991, New Jersey's P2 program has made great strides in facilitating the reduction of toxics use in the state. When analyzing P2 data, alternative methodologies could be implemented to ascertain meaningful trends. Establishing useful analyses and interpretations of data are fundamental to successful regulatory programs.

## Fate and Effects of Metals: Biogeochemical Perspective

**TP073 Metal toxicity during short-term sediment resuspension and redeposition in a tropical reservoir**

*E.C. Cervi, University of Michigan / SEAS; M. Hudson, University of Michigan / School for Environment and Sustainability; A. Rentschler, University of Michigan; G. Burton, University of Michigan / School for Environment and Sustainability*

Billings Complex is the largest water-storage reservoir in São Paulo, Brazil and has been contaminated from sewage and industrial effluents since the 1960s. Periodically, Billings sediments are subjected to currents causing resuspension which release metals. A short-term (4 h) resuspension was simulated using Sediment Flux Exposure Chambers (SeFEC) to better understand fate, bioavailability and transport of Fe, Mn, and Zn during these events and possible organism toxicity. Comparison studies consisted of contaminated and reference site sediments. *Daphnia magna* and *Hyalella azteca* were exposed during the 4 h resuspension, after 20 h redeposition, and monitored post-exposure for survival, growth and reproduction. Resuspension rapidly deoxygenated overlying water with decreasing pH, and resulted in an elevated dissolved Zn in the overlying water that remained above the USEPA criteria for acute toxicity (120 µg $L^{-1}$). However, Zn was almost totally scavenged (after 20 h) from solution as new sorption sites (i.e. OC or freshly-precipitated Fe oxyhydroxides) formed. Dissolved Mn increased continuously during and after resuspension with maximum values 20 h post exposure. An initial release of Fe occurred, likely associated with oxidation reactions of acid volatile sulfides, but decreased after 1 h of resuspension. The Fe decrease is likely due to precipitation as oxyhydroxides. As resuspended particles formed a freshly redeposited sediment layer, further oxidation occurred (up to 20 h), releasing Fe to the dissolved phase. No acute toxicity was observed during short-term resuspension; however, mortality was observed in *D. magna* and *H. azteca* 20 h post-exposure. *Daphnia magna* also showed chronic toxicity with decreased neonate production after post-exposure at both sites. This sub-lethal effect could lead decreased populations over a longer period. The adverse effects of resuspended contaminated sediments in hydrologically active systems, such as Billings reservoir, should be considered during environmental management decision-making.

**TP074 An Alternative to the Biotic Ligand Model to Explain Physiological Response to Binary Metal Mixtures in *Daphnia magna***

*D.L. Cucchiara, M. Tagmount, University of Florida / Center for Environmental and Human Toxicology; E. Traudt, Jacobs / Chemistry; J.S. Meyer, Applied Limnology Professionals LLC and Colorado School of Mines; K. Bassett, T. Mbuyu, University of Florida; C. Vulpe, University of Florida / Department of Physiological Science and the Center for Environmental and Human Toxicology; J.F. Ranville, Colorado School of Mines / Chemistry and Geochemistry*

We previously observed a non-additive protective interaction between cadmium and zinc in mixture studies in *Daphnia magna*. The observed acute toxicity of cadmium and zinc mixtures could not be explained by the individual toxicity of cadmium or zinc alone. We explored if the non-additive (protective) effect could be explained by competition between the metals consistent with a common biotic ligand model. We performed RNA-seq on daphnia exposed to each metal alone and a Cd/Zn mixture at the observed protective interaction doses. The gene expression of daphnia exposed to the Cd/Zn mixture was compared to the gene expression of daphnia exposed to cadmium only and zinc only. Our analysis of the RNA-seq data indicated that simple competition between Cd and Zn in a biotic ligand model may not fully explain the physiological (non-additive) effect. Rather, our data suggest that an organismal biologic response is the primary determinant of mixture effects. Daphnia exposed to moderately toxic doses of cadmium alone differentially expressed over 1000 genes (DEG's) at FDR < 0.1. Interestingly, we observed that in the Cd/Zn mixture, the number of DEG's was reduced to 291 DEG's as compared to Cd alone. Of these, 282 were shared in common between Cd and Cd/Zn mixture. Exposure to Zn alone at the same dose exhibited 24 DEG's. We suggest that these finding are not consistent with competition at a biotic ligand model. Biological pathway and cellular process analysis supports an organismal physiological response as playing a key role in the non-additive mixture. Diverse cellular responses were identified in the cadmium alone exposure that are consistent with the observed toxicity including induction of the unfolded protein response (UPR), antioxidant responses such as induction of glutathione biosynthesis, glutamate mediated signaling, and down regulation of genes related to digestive proteolytic enzymes. Importantly, several key responses appear to be mitigated in the mixture treatment group. Specifically, the induction of the unfolded protein response and the glutamate mediated signaling is not observed in Cd/Zn mixture. Some biological effects, such as the induction of glutathione are present in both the cadmium alone treatment and the mixture treatment group. These finding are consistent with a model in which cadmium is still bioavailable in the mixture but that Zn can prevent deleterious physiological responses. Overall, this work indicates that a biotic ligand competition model alone is unlikely to explain the explain non-additive interaction between cadmium and zinc and supports an important role for an internal physiological interaction between cadmium and zinc.

**TP075 Major physical and chemical drivers causing the spatial distribution of sediment metals in a large wave-dominated estuary in south-eastern Australia**

*J. Potts, Institute for Applied Ecology; L. Schneider, Australian National University / Department of Archaeology and Natural History / College of Asia and the Pacific; O. Furman, University of Canberra; W.A. Maher, University of Canberra / Institute of Applied Ecology; F. Krikowa, University ofCanberra / Ecochemistry Laboratory*

Lake Macquarie, on the NSW central coast of eastern Australia is a large wave dominated estuary that has two distinct northern and southern regions that receive metal and metalloid contaminant inputs from a range of urban and industrial sources located within their respective catchments. The northern region of the lake has an extensive history of large scale industrial activity with a lead–zinc smelter, a fertiliser plant, a steel foundry, collieries and sewage treatment works having operated along and discharged to the northern lake's main tributary of Cockle Creek as well as receiving contaminants from marinas, stormwater inputs from urban and light industrial precincts and sewer overflows. In the southern region, significant inputs of contaminants (i.e. selenium, copper, zinc) come from ash dam overflows and cooling water releases associated with three large coal-burning Power Stations as well as inputs from urban and light industrial stormwater sources. In this paper, we describe the spatial distribution of sediment metals in both the northern and southern regions in relation to major point and diffuse sources as well as the physical and chemical drivers influencing mobilisation, dispersion and deposition. A better understanding of the factors driving observed distributions of metals in this estuary is needed to manage and mitigate the impact of anthropogenic borne contaminants on sediment quality.

## Coupling Models With Monitoring Data and Future Perspectives for Exposure Assessment

**TP076 Estimating Human Exposure to Pesticides in Drinking Water Using Spatial Groundwater Monitoring and Pesticide Use Reporting Data, or Groundwater Modeling**

*N. Russell, E.S. Kwok, T. Barry, California Department of Pesticide Regulation / Human Health Assessment Branch, Exposure Assessment Section*

The Exposure Assessment Section (EAS) of the Human Health Assessment (HHA) Branch at the California Department of Pesticide Regulation (DPR) has developed a novel method for estimating the likelihood of human exposure to pesticides in California groundwater used as drinking water. Because groundwater exposure constitutes just a portion of aggregate exposure (which includes all potential exposures to a given pesticide due to ingestion, inhalation, and dermal contact), HHA may require more precise exposure estimates than those resulting from screening-level assessments (e.g., those used for pesticide registration reviews). Currently, HHA uses data from either the U.S. Department of Agriculture Pesticide Data Program or from the DPR groundwater Well Inventory Database to assess exposure, which may underestimate or overestimate levels of pesticide contamination in drinking water. The new method developed by EAS intends to increase the accuracy of groundwater exposure estimates. EAS proposes to derive the estimates from spatial groundwater monitoring and pesticide use reporting data, or from groundwater-solute transport modeling outputs. GIS analysis could be used for the former method to determine whether groundwater well sampling locations overlap with regions in which a given pesticide is used most heavily and whether the data are sufficient for estimating exposures. When monitoring data are lacking, exposures could be estimated based on computer simulation outputs, according to the pesticide's physicochemical properties, usage information, and site conditions (e.g., local weather; soil characteristics; etc.). EAS proposes to use a model of medium complexity, the Leaching Estimation And Chemistry Pesticide (LEACHP) model (Hutson 2003; Wagenet and Hutson 1989), because of its accessibility, precision (relative to screening-level models), and the availability of a California-specific set of environmental input parameters (developed by DPR). If some monitoring data are available, LEACHP outputs could be ground-truthed. EAS has also drafted a decision-making framework for determining whether monitoring data or modeling outputs will work best for a given pesticide and how to translate estimated pesticide residue concentrations into groundwater exposure estimates. Finally, a case-study assessment of the potential for human exposure to propyzamide (i.e., pronamide) by groundwater ingestion is included as a proof of concept.

**TP077 A Kinetic Mass Balance Model for Predicting Gas-Particle Partitioning of Low Volatility Organic Chemicals**

*M. MacLeod, F. Zhao, Stockholm University / Department of Environmental Science and Analytical Chemistry*

The extent of long range transport of chemical pollutants in the atmosphere depends on their distribution between the gas phase and aerosols. Equilibrium partitioning between the gas and particle phases is assumed in most widely used multimedia chemical fate models. Assuming equilibrium has recently been shown to overestimate the fraction of very low volatility chemicals in the particle phase. Here, we present a regional multimedia chemical fate model that includes separate compartments for fine and coarse aerosols and the gas phase. We apply the model to investigate deviations from equilibrium partitioning for low-volatility polybrominated diphenyl ethers (PBDEs) by exploring model results for; 1) seven generic aerosol scenarios, and 2) emissions to the aerosol and gas compartments. When possible, we evaluate the model scenarios against field measurements of the distribution of PBDEs between the gas phase and aerosols. The distribution of low volatility chemicals deviated from equilibrium partitioning in each aerosol scenario. The extent of the deviation is determined by the distribution of emissions to the gas phase or aerosol phase and the deposition rate, diameter and organic carbon fraction of aerosols. The deviation increased with increasing fraction of emissions to the gas phase. In a scenario with 100% of emissions to the aerosol phase, the deviations are within a factor of 1.5, while the deviations increase to up to 10^6 when 100% of chemical is emitted to gas phase. By fitting the modeled chemical distribution between the gas phase and aerosols to measurements, our model predicts that low volatility PBDEs are emitted in the aerosol phase near an e-waste recycling facility in China and to the gas phase near urban areas in Italy and Turkey. The kinetic gas/particle partitioning model presented here can predict the distribution of low volatility organic chemicals between the gas phase and aerosols more accurately than equilibrium models, and it can be readily implemented in multimedia fate and transport models.

## Wildlife Forensics Toxicology

### TP078 Secondary poisoning by pentobarbital and flunixin in a vulture feeding station in Southeastern Spain

*P. María-Mojica, University of Murcia / Health Sciences Department / Toxicology Area / Veterinary Faculty; I. Navas, P. Gómez-Ramírez, E. Martínez-López, S. Espin, P. Jiménez, A. García-Fernández, University of Murcia / Health Sciences Department – IMIB-Arrixaca – Veterinary Faculty*

Spain has the biggest colony of Griffon vultures in all Europe. The main cause of the decline in the griffon vulture population is the consumption of poisoned baits set out by people. However, sometimes another type of drugs can sometimes increase the number of individuals poisoned. Food supplied to in feeding stations is considered as a regular practice to maintenan of scavenger bird populations in those areas where food is scarce. On November 2016, the staff of the Wildlife Recovery Center “Santa Faz” found, in Alcoy feeding station (SE Spain), vultures with symptoms of weakness two days after supplying two carcasses of domestic goats. A total of five griffon vultures (Gyps fulvus) were submitted to the “Santa Faz” Wildlife Recovery Center (Alicante) to be medicated. All of them had a similar symptomatology: unconsciousness, hypothermia (between 37.7 ºC and 39.8 ºC), and shallow breathing. The treatment consisted of intravenous and subcutaneous administration of fluid therapy and maintenance of a warm environment for 3 days. Oral feeding was subsequently initiated on the basis of a soft diet with highly digestible protein. After 10 days under acute care they were released, completely recovered. Five days after the first registration, another vulture with strong symptoms of weakness was found in the feeding station. Fluid therapy was also applied in this vulture; however, it died 12 hours after admission in the WRC. At necropsy, whitish deposits were observed in the kidney, air sacs, liver and heart (visceral gout). Under suspicion of possible poisoning with a drug in the goats provided as food, the blood samples were analyzed. Blood samples of the five vultures were positive for sodium pentobarbital. After necropsy, the liver of the last one vulture was positive to flunixin, a non-steroidal antiinflammatory drug. Acknowledgements: Séneca Fundation MASCA’2014 Project (19481/PI/14). To Alvar Segui (father and son) for their invaluable service in the Canyet Project.

## Pesticide Runoff Pollution: Challenges and Opportunities in Prediction, Prevention and Management

### TP079 Effectiveness of an Integrated Wetland Treatment System in Reducing Pesticide Concentrations Associated with Agricultural Runoff

*L. McCalla, UC Davis Granite Canyon Marine Pollution Studies Laboratory / Environmental Toxicology; B.M. Phillips, B.S. Anderson, University of California, Davis / Environmental Toxicology; J. Voorhees, Marine Pollution Studies Laboratory / Environmental Toxicology; S. Zamudio, K. Siegler, R.S. Tjeerdema, University of California, Davis / Environmental Toxicology*

The central coast of Monterey County, California, is a highly productive agricultural region within the Salinas Valley that produces much of the USA’s salad greens, artichokes, and cruciferous vegetables such as broccoli, cauliflower, and Brussels sprouts. Agricultural irrigation runoff containing pesticides found at concentrations toxic to aquatic organisms poses a threat to aquatic ecosystems within the local watersheds. This study was designed to monitor the effectiveness of a constructed wetland treatment system, which is additionally integrated with the floating aquatic plant pennywort (*Hydrocotyle spp.*) and granulated activated carbon (GAC) filtration, at the reduction of pesticides associated with agricultural runoff. The wetland system is supplied with water pumped from the Tembladero Slough, an agricultural drainage that eventually enters the Monterey Bay National Marine Sanctuary. Water samples collected throughout the wetland treatment system are analyzed for toxicity to the daphnid *Ceriodaphnia dubia*, the amphipod *Hyalella azteca*, and the midge *Chironomus dilutus*. Additionally, samples are analyzed for approximately 160 fungicides, herbicides and insecticides. Preliminary results show significant input toxicity to *H. azteca* and *C. dubia*, although daphnid toxicity was likely partially caused by elevated conductivity from tidal influence. Moderate reductions in chemical concentrations were observed with water-soluble pesticides, as well as significant reductions with contaminants associated with suspended sediment. Results of this study will corroborate the efficacy of floating vegetation for water treatment, and demonstrate the efficacy of GAC treatment in a large-scale field application.

### TP080 Comparing relative efficacies of granulated activated carbon and biochar to reduce pesticide loading using laboratory bench scale experiments

*J. Voorhees, Marine Pollution Studies Laboratory / Environmental Toxicology; B.S. Anderson, B.M. Phillips, L. McCalla, S. Zamudio, R.S. Tjeerdema, University of California, Davis / Environmental Toxicology; T.M. Young, L. Wong, University of California, Davis / Civil and Environmental Engineering*

Granulated activated carbon (GAC) has been shown to reduce the pesticide load in simulated agricultural runoff. Biochar is a potentially more cost-effective and convenient alternative to GAC, but little is known of its pesticide sorbing capabilities. This study looked at the efficacy of GAC and biochar to reduce the concentration of commonly used pesticides, chlorpyrifos and imidacloprid. Experiments proceeded in two phases, each designed to simulate sixteen days of irrigation runoff events. Scaled-down experiments represented total irrigation flows of approximately 100,000 liters. The first phase treated a 1 ppb chlorpyrifos stock with individual columns of GAC, biochar, or a combination of both materials. Chlorpyrifos concentrations of the stock and post-column samples were measured daily using enzyme-linked immunosorbent assays (ELISAs). Every four days, post-column samples were analyzed for chlorpyrifos using gas chromatography/mass spectrometry (GC/MS), and for toxicity using 96-hour acute *Ceriodaphnia dubia* bioassays. Phase two was conducted with 5 ppb imidacloprid stock and fresh columns. Column breakthrough of imidacloprid was monitored every four days analytically with GC/MS. Toxicity from column breakthrough was monitored using

10-day *Chironomus dilutus* bioassays. No chlorpyrifos breakthrough was observed with ELISA measurements or toxicity. Preliminary results for the imidacloprid experiment show no post-column toxicity. Analytical chemistry results for both experiments are pending. These laboratory experiments demonstrate that biochar is a reasonable alternative to GAC for the treatment of agricultural pesticides, but field trials are necessary to confirm large-scale effectiveness.

**TP081 Mechanisms of pesticide removal from agricultural tile drainage: An assessment of woodchip bioreactor performance**

*O. Wright, M.E. Hattaway, University of California, Davis / Civil and Environmental Engineering; A.S. Burant, California Department of Pesticide Regulation / Surface Water Protection Program; T.M. Young, H.N. Bischel, University of California, Davis / Civil and Environmental Engineering*

The discharge of pesticides via agricultural drainage and runoff is a topic of increasing concern, as many of these compounds pose risks to human and environmental health. Many registered pesticides have been classified as acutely toxic, carcinogenic, and/or endocrine disrupting, and other pesticide products are employed without full knowledge of their potential toxicity. Moreover, certain chemical classes of pesticides are persistent in the environment, and some more mobile in aqueous systems, making their removal from water at the point of application desirable. Woodchip bioreactors have been recognized for their efficacy in nitrogen removal from agricultural runoff and may also provide a cost-effective method for removal of pesticides from tile drainage. Preliminary field studies demonstrated high removal of neonicotinoid and pyrethroid pesticides across woodchip bioreactors during summertime operation. The present study assesses woodchip bioreactors at laboratory and field scales for the joint removal of nutrients and pesticides from tile drainage. First, temporal and spatial removal patterns of field woodchip reactors (average hydraulic residence time 20-24h) are evaluated. Pesticide removal is characterized using both liquid and gas chromatography time-of-flight mass spectrometry, with targeted and suspect screening workflows to cover a broad range of compounds. Based on field-scale results, lab-scale reactors are constructed to identify and characterize the removal mechanisms for specific compounds and selected degradates of interest, representing major chemical classes of pesticides. These compounds include fipronil, thiamethoxam, imidacloprid and clothianidin. Variables of interest during the lab-scale study include temperature, woodchip particle size, contribution of microbial activity, dissolved oxygen concentration, and hydraulic residence time. This work helps to identify primary mechanisms for joint pesticide removal in order to optimize designs for woodchip bioreactors.

**TP082 Evaluating Consumer Behaviors to Support Refinement of Pesticide Use Assumptions in EPA's Outdoor Residential Screening Model**

*L. Padilla, Stone Environmental, Inc.; W.E. Hillwalker, D. Feifarek, SC Johnson / GSARA; M.F. Winchell, Stone Environmental, Inc. / Environmental Systems Modeling; S. Castro-Tanzi, Stone Environmental, Inc.*

The USEPA recently submitted screening-level residential model scenarios to assess exposure for outdoor consumer products as part of periodic pesticide registration reviews. The assumptions and scenarios in the screening residential models may not be characteristic of consumer use practices in terms of amounts applied, treatment sites and areas, and frequency of use. Consumer use of residential pesticide products may be sufficiently different from professional use practices that the two categories should not be evaluated with the same model scenarios in a combined risk assessment. Evaluation of consumer use practices as professional may result in overestimation of use and alter the risk assessment outcomes for outdoor residential consumer products. To refine consumer application assumptions for a typical household lot, including treatment amounts, site types, site areas and timing, we used information from consumer use surveys. Additional survey information provided refinements to timing and proportion-of-use assumptions at the watershed scale. Geographic differences in consumer product consumption associated with differences in pest pressure also provide evidence for the value of regional adjustments to application assumptions. The proposed refinements based on consumer use surveys provide realistic adjustments to the screening outdoor residential model, which may be of value during the registration review process.

## Persistence and Biodegradability Assessment

**TP084 Assessments of Biodiesel and Petrodiesel Impact on Soil Microbial Communities**

*M. Dong, D.L. Carr, Texas Tech University / Biological Sciences*

Organic pollutants could pose long-lasting impacts on the environment due to their low biodegradability. Understanding the effect of organic chemicals on microbial communities will improve not only the regulatory evaluation of environmental risk but also our understanding of biodegradation of organic compounds. Biodiesel has been considered as a viable substitute for petrodiesel mainly because it is readily degraded. However, very limited studies have examined biodiesel and petrodiesel impacts on soil microbes, and whether biodiesel is more microbial-friendly than petrodiesel is unknown. This laboratory study compared the effects of petrodiesel and three types of biodiesel on soil microbial communities in sandy-loam soil. The soil was manually contaminated with three types of biodiesel (castor ethyl ester, castor methyl ester, and safflower methyl ester), petrodiesel, and distilled water (uncontaminated control) at 2% by weight. During a 180-day incubation period, samples were collected for residual analysis and microbial 16s sequencing. GC-FID was used to detect the chemical residuals, and half-life of petrodiesel and biodiesels were calculated based on the exponential decay model. Soil microbial community composition and function were analyzed based on 16s sequencing results where potential biomarkers were identified for each contaminant. Results demonstrated that even though biodiesel showed low persistence in soil than petrodiesel, biodiesel and petrodiesel imposed similarly irreversible impacts on soil microbial communities. Biodiesel treatments decreased the diversity and ecological functions of microbial communities more than the petrodiesel treatment, and distinctive biomarkers were found in different treatments. In conclusion, our results suggested that biodiesels should not be automatically considered as harmless substitutes for petrodiesel.

**TP085 Fate of emerging micropollutants and mercury in Capbreton Submarine Canyon sediment in controlled experimentations (Biscay Bay, SW France)**

*A. Azaroff, CNRS /LCABIE-IPREM / Université de Pau / Biology and Chemistry; M. Monperrus, IPREM CNRS UPPA / Laboratoire de Chimie Analytique BioInorganique et Environnement LCABIE; C. Gassie, E. Tessier, R. Guyoneaud, IPREM CNRS UPPA*

Priority substances set by the Water Framework Directive (WFD) are of major interest to evaluate the quality of coastal and marine systems, the final receptors for pollutant emissions. Emerging substances not regulated by the WFD, i.e. personal care products and some pharmaceuticals, are of high concern since only scarce information of their occurrence, reactivity and impact are available in the deep sea sediments. In this work, transformation kinetics of mercury species (IHg,MMHg), sunscreen (ODPABA) and synthetic musk (HHCB) were studied independently from three Capbreton Canyon sediment stations according to the distance to the coast. Slurry incubations were spiked with enriched isotopic mercury species, with ODPABA and HHCB to determine methylation, demethylation potentials and degradation potentials, respectively. Those experimentations were performed under biotic/abiotic, oxic/anoxic conditions in triplicate. Mercury species analysis and emerging micropollutants analysis were performed for each kinetic times (0,1, 2, 4, 7, 11, 14 days and 0, 5, 12, 39, 50, 81, 110 days for Hg and emerging micropollutants, respectively). Taxonomic diversity (16s DNA, MiSEQ) were analysed for initial and final kinetic times to determine microorganisms diversity.

Then, microorganisms were isolated by dilution and enrichment in anaerobic and aerobic conditions. Net methylation potential were only observed under biotic conditions revealing the involvement of prokaryotes in the fate of Hg species. This was confirmed by taxonomic diversity and sequencing of *hgcA* gene, a proxy for biotic methylation. Two main families of methylating bacteria have been identified, *Desulfobulbaceae* and *Desulfobacteraceae*, suggesting their involvement in the biotic methylation process. Higher methylation potential was observed for the coastal station whereas demethylation potentials were similar for the three stations suggesting that environmental parameters (e.g. input of continental organic matter) also control methylating microbial activities. Degradation potential was only observed under biotic condition for ODPADA and fungi have been isolated. These results seem to confirm the role of the Capbreton submarine-canyon to trap, to transfer and to transform micropollutants. Half life times determination reveasl the differential resilience of such deep sea sediment for some priority and emerging substances and the key role of microorganisms.

**TP086 Lowering of the Concentration Range of the Ready Biodegradability Method OECD 301B**

*D. Riggs, Smithers Viscient; S.P. McLaughlin, Smithers Viscient / FATE; R. Brackett, Smithers Viscient / Environmental Fate and Metabolism*

The OECD 301B Guideline '$CO_2$ Evolution Test' also known as the 'Modified Sturm Test' has been a trusted method in determining if a test substance is 'readily biodegradable'. If a test substance exposed to a dilute inoculum generally comprised of activated sludge achieves 60% biodegradation equivalent to 60% of its organic carbon being converted to $CO_2$ within a 10-day window (once reaching 10% $CO_2$ evolution) during the 28-day test, the test substance can be labeled 'readily biodegradable'. However, based on the method in its current form with starting concentrations at 10 mg/L as carbon, some compounds that could potentially be biodegradable may fail this test if they are inhibitory at this relatively high concentration which may be above many compounds' Predicted Environmental Concentrations (PEC). A 301B study design was modified in this experiment by conducting the prescribed test with one of the standard reference substances, sodium benzoate, but at lower than recommended concentrations. This was conducted to determine the sensitivity of the test method at much lower and more environmentally relevant concentrations. The concentrations used in this experiment are 10, 5, 2 and 1 mg/L as carbon. The results will demonstrate if the method is appropriate at concentrations of 1/2, 1/5th and 1/10th of the lowest test concentration of 10 mg/L carbon currently recommended in the OECD 301B Guideline.

**TP087 Soil bacterial community composition is altered after the degradation of estrone and triclosan mixture**

*E. Osuji, D.L. Carr, Texas Tech University / Biological Sciences*

Wastewater derived from domestic use commonly contains mixture of pharmaceutical and personal product (PPCP), but its persistence and accumulation in the soil and the consequences for soil microbial community processes are poorly understood. Estrone and triclosan are two common PPCP of domestic wastewater. Soil microbial communities degrade a variety of PPCPs however; most studies have only addressed single compound designs neglecting the reality of their co-occurrence in nature. In this study, we examined the interaction between estrone and triclosan mixture, their potential to persist and disrupt soil microbial community function and how the microbial community react in pre-exposed soils and naïve soil. Soil with previous exposure to these chemicals (conditioned soil) and soil not previously exposed (unconditioned soil), was spiked with estrone, triclosan, and a 1:1 mixture of estrone: triclosan, and incubated for 90 days in the dark at 27°C. We examined soil microbial function dynamics using commercial Biolog EcoPlates™. Microbial degradation rates were compared over the 90 days' incubation period using high performance liquid chromatography. 16S rRNA analysis to determine changes in microbial community over time. There was significant increase in substrate activity and substrate richness in all treatments. Each microbial community utilized different carbon substrates by day 90 whereas they had exhibited similar substrate utilization at day 0. Estrone and triclosan showed the same pattern of biological degradation in both conditioned and unconditioned soils, exhibiting half-lives of 5.9-6.8 days (estrone) and 24.1-26.9 days (triclosan). The rate of degradation of the estrone:triclosan mixture was the same as the individual compounds. There was a decrease in species diversity between control at day 0 and other treatments at day 90 with establishment of unique OTUs in each treatment group at day 90. Bacillus sp. was dominant in all the day 90 treatments. Soil microbial communities can degrade estrone and triclosan in the soil thus preventing accumulation in soil and subsequent contamination of ground water.

**TP088 What's in your laundry detergent? An evaluation of common surfactants found in laundry detergents and their PBT characteristics**

*P. Chowdhary, S.N. Vivanco, C. Kelly, A. Leiga, Wood Environment & Infrastructure Solutions, Inc*

In the past, high performance surfactants such as nonylphenol ethoxylates (NPEs) were widely used in commercial laundry operations. California Department of Toxic Substances Control (DTSC) recently developed a Product-Chemical Profile on NPEs in laundry detergents under the framework of its Safer Consumer Products Regulations. This framework identifies specific product-chemical combinations that have the potential to expose people or the environment to a harmful hazardous chemical. When released into the environment, NPEs and their degradation products can persist and accumulate in the aquatic environment, potentially causing harm to fish and aquatic invertebrates, and impair wildlife growth, reproduction, development, and survival. A voluntary industry phase-out of NPEs was initiated in 2010, with the goal of complete phase-out from all detergents by 2014. Although chemical alternatives may be used in lieu of NPEs, it is important to characterize potential adverse impacts to people and/or the environment. We surveyed common household laundry detergents to evaluate the chemical alternatives of NPEs and their effect on human health and the environment according to persistence, bioaccumulative, and toxicological (PBT) properties.

## Integrating Big Data into the Bigger Picture

**TP089 A Multi-omic Approach to the Analysis of Organism Responses to Great Lakes Sediment, Effluent and Surface Water Exposures**

*D. Simmons, Denina Simmons Scientific Consulting / Biology; B. Chandramouli, H. Butler, J. Cosgrove, SGS AXYS; T. Watson-Leung, Ontario Ministry of the Environment Conservation and Parks / Aquatic Toxicology Unit; S. Kleywegt, Ontario Ministry of Environment and Climate Change / Standards Development Branch; P.A. Helm, Ontario Ministry of the Environment & Climate Change / Environmental Monitoring and Reporting Branch; C.C. Helbing, University of Victoria / Biochemistry & Microbiology; J.P. Sherry, Environment and Climate Change Canada / Water Science Technology; B. Duncker, University of Waterloo / Biology*

Sediment, effluent and surface water samples were collected from various sites across Hamilton Harbour, Toronto Harbour, Humber Bay and Lake Erie between 2014 and 2015. Larval Hexagenia sp. and sexually immature rainbow trout were exposed to these samples in the laboratory for 48 hours. Liver, plasma, and fin tissue were collected from exposed and control rainbow trout while exposed and control Hexagenia were collected whole. Levels of 11 transcripts in rainbow trout and 7 in Hexagenia were measured. Shotgun proteomics data were generated for Rainbow Trout and Hexagenia. Two hundred and nineteen metabolites including amino acids, lipids, bile acids, and fatty acids were quantified. A total of over 500 individual contaminants and water quality indicators were measured in the effluent, surface water, and sediment samples. Results showed distinct signatures by exposure type. Metabolomics data in Hexagenia exposed to sediment from Hamilton Harbour sites with high persistent organic pollutant concentrations showed 60 metabolites differing significantly between sites and correlating with contaminant levels. Two transcripts also showed statistically significant differences between these sites. One hundred and one Hexagenia proteins had significantly different levels following exposure to Hamilton Harbour effluent samples. It is expected that the combination of 'Omic results will have higher differentiating power than data from a single endpoint measurement. However, this may not be so for rainbow trout which were generally less responsive than Hexagenia – possibly due to differences between these two species and their relative levels of exposure.

**TP090 Untangling Adverse Outcome Pathway Networks: Extracting, Benchmarking, and Applying Emergent AOP Knowledge**

*J. O'Brien, Environment and Climate Change Canada / National Wildlife Research Centre; N. Pollesch, USEPA / ORD / NHEERL / Mid-Continent Ecology Division; D.L. Villeneuve, USEPA / National Health and Environmental Effects Research Laboratory*

As the community of toxicological researchers and risk assessors adopt the adverse outcome pathway (AOP) paradigm for organizing toxicological knowledge, the number and diversity of AOPs in the online AOP knowledge base (KB) continue to grow. To characterize this growth, we assembled all AOPs in the KB into a network and measured several benchmarking properties including basic summary information, and network structure and connectivity metrics. We then identified and quantified the emergence of new knowledge that resulted from combining all AOPs into a single network. We found that networking the 187 user-defined AOPs described in the KB resulted in the emergence of 9405 unique, previously undescribed, linear AOPs (LAOPs). An AOP-KB growth simulation was used identify factors than influenced the rate of new LAOP emergence. We found that the creation of new AOPs that borrowed components from previously existing AOPs in the KB was the most relevant factor for the emergence of LAOPs, but that the introduction of non-adjacent key event relationships and feedback cycles were also important factors. Finally, we provide examples of how to identify application-specific paths of interest from this large number of LAOPs using a weighted path approach. These results show that the AOP-KB network may have considerable value as a source of emergent toxicological knowledge. These findings are not only helpful for understanding the nature of this emergent information, but can also be used to manage and guide future development of the AOP-KB, and to tailor AOP information to specific risk assessment and research applications.

## The Use of Historical Control Data in Ecotoxicological Study Assessments

**TP091 A Review of the Time to Hatch Endpoint in Fish Early Life-Stage Studies with Fathead Minnow**

*L. Fernandes, Smithers Viscient Laboratories / Aquatic Toxicology; J. Marini, Smithers Viscient / Aquatic Toxicology; L. Sayers, R.C. Biever, Smithers Viscient / Department of Ecotoxicology*

Early development is considered an especially sensitive stage in the fish life-cycle. As a result, many regulatory agencies recognize the fish Early Life-Stage (ELS) test as an important component of environmental risk assessments. The most recent revision of EPA guideline OSCPP 850.1400 updated the list of recommended endpoints for the fish ELS to include mean time to hatch. This endpoint represents the mean elapsed time between test initiation and completed hatch for the embryos in a replicate. Hatch observations are typically performed once daily, along with other biological observations. This endpoint is thought to be most suitable in fish ELS studies with species that exhibit hatching behavior over a longer hatch period (i.e., rainbow trout, the recommended freshwater fish species in this guideline), but the relevance of the endpoint is less understood in test species with shorter hatch periods. This review examines the control mean time to hatch for ten fish ELS studies conducted with fathead minnow (*Pimephales promelas*) since the implementation of OCSPP 850.1400 (2017 – 2018). Further, analyses were performed on complete study data sets to determine if the mean time to hatch endpoint could be correlated to subsequent fish ELS endpoints (i.e., size; measured as total length and/or either wet or dry weight, and post-hatch success) to indicate whether mean time to hatch is a relevant predictor of subchronic toxicant related effects. Review found that mean time to hatch across the ten studies was 3.5 days (S.D. 23%). On an individual organism basis, 31.6% of organisms hatched by test day 3, 68.0% hatched by test day 4, and 0.5% hatched by test day 5. Correlational analyses on whole study data sets found that there was no correlation between the mean time to hatch endpoint and any of the other subsequent endpoints in 7 of the 10 studies examined. The remaining three studies showed significant correlations between mean time to hatch and the size and post-hatch success endpoints. However, all but one test showed a stronger correlation between post-hatch success and size than between those endpoints and mean time to hatch. The remaining study demonstrated strong statistically significant effects in the size endpoints as well as mean time to hatch. These results raise the question of whether the mean time to hatch endpoint as measured is suitable as a predictor of biologically relevant subchronic toxicant related effects in less extreme data sets.

**TP092 An Examination of Historical Control Data and Endpoint Sensitivity for Tier I Honey Bee Laboratory Studies**

*C.R. Picard, Smithers Viscient / Terrestrial Ecotoxicology; M.R. Patnaude, K.A. Rathjen, Smithers Viscient LLC / Ecotoxicology*

Tier I laboratory honey bee testing as defined by the Environmental Protection Agency (EPA) Office of Pesticide Program include test methods that are described by either draft or recently finalized OECD guidance. These tests include the larval acute oral exposure (OECD 237 Guideline), larval chronic oral exposure (OECD 239 Guidance Document) and adult chronic oral exposure (OECD 245 Guideline). Smithers Viscient has begun to compile data for the Tier I testing as a result of the recent influx of data-call-ins issued by the EPA for agrochemical product registration that require information from these exposures. In this poster, historical control data is presented and compared against acceptability criteria. As these test methods are rather novel relative to other ecotoxicity testing, control performance will also be tracked over time to assess if laboratory experience is a factor in achieving acceptable results. In addition, trends in endpoint ($LD_X$/$ED_X$) sensitivity will be examined across the three tests types to define any correlations in terms of toxicity. The growing database and experience with Tier I laboratory honey bee testing may be utilized to highlight any potential redundancy in the testing strategy (single dose larval acute and repeated dose larval chronic) or increase the ability to better predict toxicity using the results of a single test type.

**TP093 New Daphnia magna Historical Control Data Needed to Evaluate Chronic Study Results**

*A. Shaw, A.E. Fournier, R.C. Biever, Smithers Viscient / Department of Ecotoxicology*

Historical control data (HCD) is useful to support results of a study when a data set may be unclear due to high or low control variability. The reproductive endpoints for *Daphnia magna* chronic testing have changed recently with the finalization of the OCSPP 850.1300 guideline. Additional response variables are now required including $F_0$ production rate of first brood release and number of live offspring per $F_0$ adult per reproductive day. Since collection and calculation of these response variables only began after the 850.1300 guideline was finalized in October of 2016, the historical database for these endpoint requirements is limited. Additionally, the statistical evaluation of the multiple reproductive endpoints can lead to conflicting results within a single data set. Daphnid length data typically has low variability and many years of data collection has provided an extensive historical control database. Since this endpoint demonstrates low variability, it is common for slight differences in daphnid length to be significantly different when compared to the control while still remaining within historical ranges and likely not biologically relevant, especially at a population level. Since low variability can cause statistical analysis to become overly sensitive, the extensive historical database for length data can assist in such cases to make an argument for adjustment to the statistically determined NOEC value based on these historical data values. The recently required daphnid reproduction response variables also have low variability in the data sets collected so far, especially the production rate of first brood endpoint. Based on the daphnid life cycle, brood release is typically within a two-day period and with once daily observations, this endpoint does not provide a true biological difference unless outside of the historical range. Using the daphnid length data as a model, gathering more historical control data on the production rate of the first brood endpoint will likely prove to be helpful in instances where low variability yields uncertain or unreasonable endpoint results.

## Chemical Mixtures in Urban Systems – Screening and Prioritization of Emerging Contaminants

**TP094 Identification of emerging micropollutants in effluents from WWTP, Korea via suspect and nontarget screening**

*C. Younghun, Changwon National University / FEED of Eco-Friendly Offshore Structure; J. Jeon, B. Moon, Changwon National University / Environmental Engineering*

Over the last decades, many environmental pollutants such as pharmaceuticals, personal care products, and pesticide have been studied in water system. However, there are many other substances that are still unknown and/or excluded from the target list for chemical analysis. To identify them, suspect and nontarget screening have been applied using LC-HRMS analyzing accurate mass. In the present study, we tentatively identify emerging micropollutants in effluents which have never reported or less information in Korea. The effluent samples were taken respectively at the 7 WWTPs, which discharge effluent to the Nakdong River basin in September, 2016 and analyzed via suspect and nontarget screening using LC-HRMS (QExactvie+ Orbitrap). As the results, 14 pharmaceuticals (e.g., amisulpride, losartan, niflumic acid, etc), 5 metabolite (e.g., 2-amino-6-methylmerca albendazole sulfone, etc), 2 herbicide (e.g., ametryn, atratone), 3 Etc (e.g., 4-methylbenzotriazole, tributyl citrate acetate, tributyl citrate) were tentatively identified in the effluent samples. 4-methylbenzotriazole used as a corrosion inhibitor was showed the highest intensity. 4-methylbenzotriazole, niflumic acid (drug used for joint and muscular pain) and tributyl citrate acetate (plasticizer) were detected the highest frequency. Dihydrocodeine, an opioid narcotic analgesic was identified in 4 effluent. Valsartan acid was identified in the 6 effluent. Of the tentatively identified 24 compounds, amisulpride, fexofenadine and losartan were confirmed with reference standard. Confirmation and quantitative analysis of the remained substances is currently under study.

**TP095 Identifying and assessing the toxicity of transformation products formed during oxidative water treatment**

*S.L. Nason, C. Prasse, Johns Hopkins University / Environmental Health and Engineering*

Oxidation processes used for water treatment transform many commonly detected organic environmental contaminants. It is often assumed that “removing” the contaminant molecules will reduce the toxic effects that may be caused by their presence. However, transformation products can also have biological effects and in some cases their toxicity exceeds that of the parent molecule. Even a single compound can produce a complex mixture of transformation products, and determining ways to evaluate which mixture components are potential causes of toxicity is an important step in assessing contaminant removal systems and prioritizing contaminants for removal. We studied personal care product ingredients that are frequently detected in wastewater treatment effluent and swimming pools, and identified their transformation products using high resolution mass spectrometry. Additionally we measured adducts formed from reactions between transformation products and biomolecules as a way to identify transformation products and pathways that may have unintended negative effects on organisms.

**TP096 Profiling and Identification of Poly- and Perfluoroalkyl Substances (PFAS) in Wastewater Treatment Plant (WWTP)**

*M. Wang, ECL California Dept. of Toxic Substances Control / Enviromental Chemistry Laboratory; E. Houtz, ARCADIS; W. Duong, California Environmental Protection Agency / Department of Toxic Substances Control / Environmental Chemistry Laboratory; J. Park, California Environmental Protection Agency / Department of Toxic Substances Control*

The current and historic usage of aqueous film-forming foam (AFFF) at military and civilian sites have drawn much attention in recent years due to possible linkage to poly- and perfluoroalkyl substances (PFASs) contamination in water systems. Recently, PFASs were measured at relatively high levels in effluent in some San Francisco Bay Area wastewater treatment plants that were impacted by AFFF usage. However, PFASs identified using targeted analysis methods are only a small portion of the PFAS known to be present in AFFF formulations. As a follow-up study, high resolution mass spectrometry (HRMS) was commissioned to investigate the PFASs at an airport wastewater treatment plant during an AFFF introduction event. AFFF-derived PFASs and their transformation products were identified using high resolution quadrupole time of flight mass spectrometry (QTOF/MS). Using a combination of targeted and non-targeted analysis (NTA) approaches, molecular features that were extracted from the raw total scan chromatography were screened, prioritized and tentatively identified with compounds from an in-house PFAS database. For prioritized features that have no database match, chemical formulas were generated based on exact mass, isotope distribution and isotope spacing. We preliminarily identified the presence of various PFASs known to be present in fluorotelomer-based AFFF formulations, including 6:2 fluorotelomermercaptoalkylamido sulfonate (FTSAS), 6:2 fluorotelomer sulfonamide alkylbetaine (FTAB), their homologues from 4:2 to 12:2, as well as various transformation products, primarily derived from the biological oxidation of 6:2 FTSAS within the treatment plant. We identified novel PFASs, proposed their structures and possible transformation routes. Optimized working flow with a focus on PFASs were proposed. The unknown screening approach combined with the profile comparison (influent vs. effluent) is critical in establishing PFAS transformation intermediates and products, their fates in the wastewater treatment plant, and assessing potential impact to the Bay water system.

**TP097 Pharmaceutical of emerging concern in urban wastewaters from Costa Rica: The case of Levofloxacin, Atenolol and Sulindac using oDGT passive sampling**

*A. Ledezma, Instituto Tecnologico de Costa Rica / Chemistry; F. Roa-Gutierrez, Instituto Tecnologico de Costa Rica / Chemistry Department; C.S. Wong, University of Winnipeg / Department of Chemistry; J.K. Challis, University of Manitoba / Chemistry; K. Luong, University of Winnipeg / Richardson College for the Environment; L.G. Chaves-Barquero, University of Manitoba / Department of Chemistry*

The occurrence of the fluoroquinolone Levofloxacine, b-blocker Atenolol and NSAID Sulindac was evaluated in the urban wastewaters from the Great Metropolitan Area in San José, Costa Rica. Sampling sites were located in a major hospital, the most important wastewater treatment plant of the city and the river highly polluted of the area. Passive sampling using oDGT technology was applied by allowing continuous samplers in each site for a 15 day period during 2017. The quantitative analysis was performed using liquid chromatography-electrospray ionization tandem mass spectrometry. According the environmental concentrations (TWA) found, maximum concentrations of 1853 ng/L for Levofloxacin and 532 ng/L for Sulindac, were detected in the hospital effluent, while 3948 ng/L was for Atenolol in the treatment plant. Results corroborated that primary and secondary treatment facilities don´t reduce the contamination for the studied drugs. Due to the tropical climate of Costa Rica, direct photolysis was studied as a principal fate process, through the photochemical property of the quantum yield (φ) and the pH influence, finding values of $\varphi$=0,101 for Levofloxacin and $\varphi$=0,0791 for Sulindac at pH 7. These results show the potential risk that could affect to the aquatic ecosystems and the general public exposed, and could help to the health and environmental authorities, to consider investments in advanced technologies for the treatment of the wastewaters in the country. Key words: pharmaceuticals, Levofloxacin, Atenolol, Sulindac, emerging contaminants, urban wastewaters, Costa Rica

**TP098 Emission characteristics of Dioxins and HCB, PeCBz of MSWs prevention facility in the Republic of Korea**

*M. Kwak, Korea Environment Corporation / Environment Security*

Introduction : Total generation amount of the municipal solid waste in Korea is steadily on the rise, according to literature sources and representative removal method of this waste is incineration. In case of Municipal solid waste incinerators(MSWs), it could occur harmful substance being unintentionally produced Persistant organic pollutants(POPs) including Dioxins(PCDD/Fs), Hexachlorobenzene(HCB) and pentachlorobenzene(PeCBz). In this study, we analyze POPs(PCDD/Fs, HCB, PeCBz) concentration from stack through prevention facility focused on MSWs and check correlation of unintentional PCDD/Fs and HCB, PeCBz. and a composition of each prevention facility was classified to 4 group(A,B,C,D). Group A is CC→WHB→SDR→BF→STACK, B is CC→SNCR→WHB→SDR→BF→Stack, C is CC→WHB→SDR→BF→SCR→Stack. D is included to BF→WS process. *CC:Combustion Chamber, WHB:Waste Heat Boiler, SCR:Selective Catalytic Reduction, SNCR:Selective Non Catalytic Reduction, SDR:Semi Dry Reactor, WS : Wet Scrubber <strong>Materials and Methods : Sampling was proceeded from 2014 to 2016 at concentration of PCDD/Fs, HCB, PeCBz. The measurement and analysis of them formed based on the POPs official standard. All particulate and gaseous matter collected by stack sampler(KXC-572, APEX) were extracted by soxhlet extraction with toluene over 17hours then subjected to a series of clean-up columns including acidic multi-layer silica gel columns and activate basic aluminum oxide column. HCB and PeCBz conducted only multi-layer silica gel columns. After reference satandard substance was injected to final concentration solution, it was analyzed with HRGC/HRMS for PCDD/Fs and HRGC/LRMS for HCB&PeCBz Results : The concentration correlation between Dioxins and HCB, that between Dioxins and PeCBz in a variety of waste type(industrial, municipal, specific and medical waste) results in the insignificant relationship except for MSWs. Facility of C set to after SCR indicates low average concentration of all POPs( PCDD/Fs, HCB, PeCBz) and is 0.003 ng/Nm3, 0.000 ng/Nm3, 0.032 ng/Nm3 respectively. In the case of D group included WS, It is relatively higher than these group and concentration of POPs (PCDD/Fs, HCB, PeCBz) is 0.504 ng/Nm3, 32.949 ng/Nm3, 120.883 ng/Nm3 respectively. This suggests that prevention facility using SCR process provided the better efficiency and which using WS process could cause decline efficiency of the removal of PCDD/Fs.

**TP099 Comprehensive nontarget analysis of sediment and aqueous environmental samples via SPE LC-ESI-HRMS: A case study for the Florida Everglades**

*C. Henderson, Florida International University / Chemistry; B. Ng, Florida International University / Chemistry and Biochemistry; N. Quinete, Florida International University / Analytical Chemistry; P.R. Gardinali, Florida International University / Chemistry & Biochemistry and SERC*

The Contaminant Assessment and Risk Evaluation (CARE) Project was an extensive study that aimed to assess and inform resource managers about risks to the ecosystems of Everglades National Park, Biscayne National Park, and Big Cypress National Preserve. The analyses for the project included organochlorine pesticides, trace metals, and contaminants of emerging concern, such as pharmaceuticals and personal care products. Recently, citizen complaints and public reports of potential contamination near Everglades City and Chokoloskee Bay have renewed the interest in assessing the current conditions in the bay and nearby coastal basins. To this end, sediment and water samples were collected seasonally from six sites across the transect of the Barron River through Everglades City, Florida, and a method for the comprehensive nontarget analysis of aqueous and sediment samples was developed. Water samples were analyzed for environmental parameters on site and bulk organic matter characterization by fluorescence before nontarget analysis via an online solid phase extraction liquid chromatography coupled to an electrospray ionization-high resolution mass spectrometer (SPE LC-ESI-HRMS). Compared to previous reports, a different approach in terms of sediment sample preparation was performed, where samples were sequentially extracted by accelerated solvent extraction (ASE) with water, methanol, and acetonitrile before HRMS analysis of each fraction. Nontarget data interpretation was undertaken on Thermo Scientific's Compound Discoverer 3.0 using a routine workflow for identification of unknown environmental contaminants. Initial data assessment shows an increasing chemical diversity as sampling moved along the north-south transect from natural waters to an urban environment, with primarily natural products and some human tracers detected at northern sites, with the introduction of plasticizers, surfactants, and various pharmaceuticals appearing in increasing variety in southern sites.

**TP100 There must be something in the water: Non-targeted assessment of emerging contaminants in North Carolina drinking water sources**

*L. Ferguson, Duke University / Nicholas School of the Environment / Department of Civil and Environmental Engineering; J. Ulrich, Duke University / Department of Civil and Environmental Engineering; S. Perkins, Catawba Riverkeeper; M. Starr, Upper Neuse Riverkeeper; E. Sutton, Haw Riverkeeper*

Discovery of the emerging polyfluorinated alkyl substance GenX at elevated concentrations in ambient waters and finished drinking waters of the Cape Fear region in North Carolina in 2016 has led to increased awareness of the problems surrounding emerging organic contaminant occurrence in drinking water sources in the State. We have conducted periodic water sampling at drinking water intakes located in the Neuse, Haw, and Catawba river basins in North Carolina for subsequent emerging pollutant reconnaissance. These sites span the range of industrialized (Haw), urbanized (Catawba), and agriculturally-dominated (Neuse) watersheds, reflecting multiple land uses and potential emerging pollutant sources to drinking water sources. Samples were analyzed using a novel LC-HRMS/MS based workflow, with data acquisition conducted on an Orbitrap Fusion tribrid MS and compound detection, prioritization, identification, and functional use classification performed using custom cheminformatic and computational scripts. Our results indicated a complex mixture of natural and anthropogenic organic compounds in NC surface waters, with analytical signals detected for > 5,000 discrete compounds, and high-confidence tentative structural ID's for > 300 of these. The tentatively identified compounds present at high relative intensity included markers of wastewater (e.g. sucralose, methylbenzotriazoles, and pharmaceuticals), stormwater (e.g. benzothiazole and substituted urea and guanidine vulcanization accelerants), and agrochemical input (e.g. simazine, atrazine, and fungicides such as carbendazim). In general, the urbanized and industrialized watersheds were dominated by stormwater markers and wastewater-derived contaminants, while the rural, agricultural watersheds appeared to show elevated levels of pesticides and other crop management chemicals, consistent with apparent land use. Finished drinking waters were enriched in apparent oxidative transformation products and natural products relative to raw waters, consistent with formation during drinking water disinfection. In some cases finished drinking waters collected from newly constructed buildings showed evidence of elevated plasticizers and other polymer additives, possibly leached from new water delivery infrastructure in the buildings. Overall, our results illustrate occurrence of diverse emerging contaminants in raw and finished drinking waters within the state of North Carolina.

## Linking Mechanism of Action to Physiological and Ecological Effects in Aquatic Species

### TP101 Estrogenic potential of Cyclohexylphenylketone as mediated through metabolic activation in rainbow trout

*J. Serrano, USEPA / ORD / Systems Toxicology Branch; M.A. Tapper, R.C. Kolanczyk, USEPA ORD / National Health and Environmental Effects Research Laboratory / Mid-Continent Ecology Division; A. Kubatova, University of North Dakota / Department of Chemistry; T. Lahren, USEPA / ORD / NHEERL Mid-Continent Ecology Division; J.S. Denny, USEPA / Mid-Continent Ecology Division*

Phenones and hydroxy-benzophenones are widely used as UV radiation filters, and in the manufacturing of insecticides and pharmaceuticals. Understanding the estrogenic potential of these chemicals is of interest to the US Environmental Protection Agency (USEPA) and the international community. The current study sequentially combined complementary in vitro rainbow trout estrogen receptor (rtER) binding and liver slice vitellogenin (Vtg) mRNA induction assays in the context of a defined ER-mediated Adverse Outcome Pathway (AOP). Cyclohexylphenylketone (CPK), which did not bind to the rtER in cytosol, was biotransformed within liver tissue to one or more metabolites that induced Vtg expression. In absence of Standards, nine CPK metabolites were identified by combining gas chromatography-mass spectrometry (GC-MS) with and without derivatization, liquid chromatography (LC) with tandem MS, and LC with high resolution time of flight (ToF) MS spectra information. LC fractionation showed relationships between LC- and GC-MS data needed to assess substitution patterns. Results supported that CPK is primarily metabolized through phase I oxidation of the cyclohexyl ring and not the phenyl group as anticipated. Two metabolites (M1 and M2; MW 186) were analyzed by GC-MS and enzyme conjugation studies and proposed to be cyclohexenyl-derivatives. M6-M9 were confirmed using derivatization techniques as hydroxylated metabolites (MW204), with the potential for undergoing phase II conjugative metabolism to glucuronides and sulfates. Lastly, M3, M4 and M5 were identified as cyclohexanone-derivatives of CPK (MW 202), resulting from the redox interconversion of the hydroxylated metabolites. Information obtained allowed the proposal of a novel metabolic pathway and potential adverse effect mechanism for cyclic phenones in rainbow trout liver slices.

### TP102 Cholinesterase inhibition by sublethal exposure of organophosphate pesticides can reduce the ability of a tropical freshwater fish to escape predation

*N. Sandoval Herrera, University of Toronto, Scarborough / Ecology and Evolutionary Biology; F. Mena, Universidad Nacional / Instituto Regional de Estudios en Sustancias Toxicas; M. Espinoza, A. Romero Vasquez, Universidad de Costa Rica UCR*

The continuous discharge of pesticides from agricultural activities have negative effects on aquatic organisms and ecosystems. Highly toxic pesticides like organophosphates have low persistence in the environment but are applied very frequently in crops, becoming an eminent threat for aquatic ecosystems. Biomarkers are use in ecotoxicology to study toxicant effects at low concentrations of exposure. However, most sublethal studies examined biomarkers at low levels of biological organization, mainly cellular, which lack evident ecological relevance. In order to understand the ecological implications of such effects it is necessary to evaluate responses at different levels of biological organization (sub-individual, individual level), and study their interactions. We used a multibiomarker approach to estimate the toxic effects of ethoprophos, an organophosphate insecticide commonly used in banana plantations, on the tropical fish *Astyanax aeneus* (Characidae). We measured biomarkers at sub-individual (cellular) and individual (metabolism, behavior) levels and examined cause-effect relationships among these responses. Exposed fish showed a significant inhibition of brain Cholinesterase (ChE) enzyme activity (57%), reflecting the high pesticide neurotoxicity. However, other biomarkers like oxidative stress (CAT, LPO), biotransformation reactions (GST), and resting metabolic rate were not affected by the pesticide. Antipredator behaviors such as predator avoidance and risk assessment (light/dark preference) were modified by the pesticide exposure. Exposed fish escaped slower from a simulated predator attack and showed preference for brighter areas in a novel tank, changes that might increase predation vulnerability. Escape time was negatively affected by ChE activity, suggesting that pesticide-induced cholinesterase inhibition increases escape time. Ethoprophos caused disruption of essential cellular processes, leading to behavior impairment which might cause a detriment in the fish ecological performance. These results provide evidence that impacts of organophosphates pesticides on fish population can occur even at short exposures at very low concentrations. By using a mechanistic approach, individual responses can be scaled up to population effects, improving the estimation of pesticide effects on wildlife and giving a higher predictive ability to risk assessment studies.

### TP104 Bifenthrin as an endocrine disrupter: Linking the mechanism of estrogenic effects of bifenthrin exposure to sex determination alteration in zebrafish

*P. Mundy, UC Davis / Anatomy, Physiology & Cell Biology / School of Veterinary Medicine; B.W. Draper, University of California, Davis / Molecular and Cellular Biology / College of Biological Sciences; R.E. Connon, University of California, Davis / Anatomy, Physiology & Cell Biology, School of Veterinary Medicine*

Bifenthrin is a commonly used pyrethroid insecticide, and a known endocrine disrupting compound. Bifenthrin has been shown to have estrogenic effects in fish, eliciting increases in plasma 17-β-estradiol (E2) and upregulation of genes downstream of estrogen receptors (ERs) including *vitellogenin*. Further, our preliminary data suggest bifenthrin can alter sex determination in wildtype zebrafish. Because bifenthrin has been shown in cell culture to bind to and activate ?estrogen receptors, and elicit estrogenic responses in vivo, it has been assumed that ?bifenthrin acts as an ER agonist in vivo.? However, due to the presence of endogenously produced estrogen confounding a primary vs. secondary effect, the direct activation of ERs by bifenthrin has yet to be confirmed in vivo. The goal of this project is thus to determine in vivo if bifenthrin directly activates ERs. To measure ER activation directly, as opposed to downstream events, transgenic estrogen receptor reporter fish were used. Tg(*5xERE:egfp*) fish produce green fluorescent protien (GFP) driven by estrogen response elements. Tg(*5xERE:egfp*) fish were exposed to bifenthrin at environmentally relevant concentrations as either larvae or juveniles, and evaluated for GFP mRNA abundance via quantitative polymerase chain reaction (qPCR). Consistent with previous findings that bifenthrin is estrogenic in juveniles and anti-estrogenic in larvae, bifenthrin was found to increase relative GFP in juveniles by 1.4 log2 fold-change at 10ng/L, and slightly decrease relative GFP in larvae by 0.3 log2 fold-change at 10ng/L, as well as alter estrogen receptor and cytochrome expression. These results support that the Tg(*5xERE:egfp*) fish can be used to measure the endocrine disrupting effects of bifenthin at environmentally relevant concentrations. Additionally, we show ER activity in response to bifenthrin exposure in the absence of endogenously produced estrogen by using null mutants for the aromatase responsible for estrogen production. Using zebrafish as a model species, the results reveal valuable knowledge of endocrine disruption mechanism linked with physiological outcome applicable to wild fish populations and humans at risk from exposure to this commonly used insecticide.

**TP105 Use of CRISPR/Cas9-mediated gene disruption in Xenopus tropicalis to evaluate thyroid-related targets of toxicological concern**

*J. Haselman, USEPA / NHEERL / Mid-Continent Ecology Division; J. Christensen, USEPA; J.H. Olker, USEPA / ORD / NHEERL, Mid-Continent Ecology Division; P.A. Kosian, K.G. Donnay, USEPA / NHEERL / Mid-Continent Ecology Division; P. DeGoey, USEPA; M.W. Hornung, S.J. Degitz, USEPA / ORD / NHEERL / Mid-Continent Ecology Division*

CRISPR/Cas9-mediated gene editing is now an easily employed straightforward tool for studying gene function and has logical applications in the field of toxicology. Functional knockout of a protein implicated as a toxicological target serves as a highly specific method to evaluate downstream biochemical and apical effects when a molecular target is perturbed – in lieu of model chemical exposures. This approach could prove most useful for molecular targets that are not yet well-characterized by traditional toxicological approaches involving exposures to model chemicals or for targets where model chemicals are unidentified. To demonstrate the effectiveness of gene editing for thyroid disruption research, we employed the CRISPR/Cas9 system to knock out the thyroperoxidase (TPO) gene in model amphibian species *Xenopus tropicalis*. Newly fertilized embryos were microinjected with CRISPR/Cas9 ribonucleoprotein (RNP) complexes designed to target three different sites within the TPO gene. The viable larvae for each of the RNP-injected, non-injected and mock-injected groups were grown out in flow-through tanks for continued evaluation. All of the surviving non-injected controls and mock-injected larvae completed metamorphosis with a median metamorphosis time of 48 days (n = 85 and 42, respectively). Of the surviving RNP-injected larvae, 70 out of 89 completed metamorphosis with a median metamorphosis time of 48 days while 19 putative knockouts were arrested at Nieuwkoop and Faber stage 55 (onset of pro-metamorphosis). This arrested development phenotype was consistent with previous studies of TPO inhibition by exposure to potent model TPO inhibitors. The DNA of larvae with putative TPO knockout was confirmed to have persistent mutations in the targeted regions of the TPO gene by Sanger sequencing, supporting the specificity of the apical effects. As demonstrated here with a well-characterized mechanism of thyroid toxicity, CRISPR/Cas9-mediated gene editing will support the linkages between a putative molecular target, downstream biochemical effects and adverse organismal outcomes, facilitating the advancement of predictive approaches to chemical safety evaluation.

**TP107 Pharmacokinetics of Anticoagulant Rodenticides in Largemouth bass and Black triggerfish**

*R. Riegerix, University of Missouri, Columbia / Biological Sciences; D.E. Tillitt, R.W. Gale, M. Tanner, USGS / Columbia Environmental Research Center*

Anticoagulant rodenticides (ARs) have been used for decades with limited knowledge of acute and chronic effects on non-target species, especially fish species. Our previous studies have demonstrated a high concentration of ARs was needed to elicit mortality in fish we have tested. Little to no information on the ADME (absorption, distribution, metabolism, and elimination) of ARs in fish exists. Using sub-lethal intraperitoneal injection (IP) doses, we monitored ARs in various tissues over time to determine the pharmacokinetics of ARs. Our species of interest, largemouth bass (LMB, *Micropterus salmoides*) and black triggerfish (BT, *Melichthys niger*), were dosed with a sublethal concentration of a designated AR, diphacinone (DPN) and/or brodifacoum (BROD). Liver, muscle and plasma were analyzed for AR concentrations over a 120 hour period. Blood clotting assays were also conducted to determine changes over time due to AR exposure. In LMB, the greatest concentrations were observed in the liver (13.03 µg/g +/- 8.52) and plasma (12.36 µg/g +/- 5.68) at 48 hours post-exposure. Clotting times increased following DPN exposure, peaking at 96 hours (average 22 seconds), then decreasing at 120 hours (average 7.75 seconds) in LMB. Exposure to DPN in BT or BROD in LMB also demonstrated an increase (up to 72 hours) and subsequent decrease (96-120 hours) in clotting times. Estimation of clearance times of ARs in fish will aid efforts to determine the risks residues may pose due to secondary exposure.

**TP108 A combined PBTK and qAOP-modeling approach to assess the impact of DLC-induced embryotoxicity on recruitment failure in European eels**

*M. Brinkmann, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre; M. Freese, J. Pohlmann, Thühnen-Institute for Fisheries Ecology; J. Doering, National Research Council at USEPA, Duluth; M. Damerau, L. Marohn, R. Hanel, Thühnen-Institute for Fisheries Ecology; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre*

The panmictic stock of the European eel (*Anguilla anguilla*) has seen a dramatic decline over the past several decades, and declines in recruitment as a result of maternally transferred contaminants has been proposed as one of several potential causes. In particular, dioxin-like chemicals (DLCs) have been identified as a class of chemicals of great concern for both European and American eels (*Anguilla rostrata*). DLCs bioaccumulate, are highly embryotoxic in many species of fish, and maternally transferred in artificially matured eels. However, to date researchers have been unable to locate reproducing adult eels or developing embryos in their natural spawning grounds in the Sargasso Sea. As a result, accurate embryotoxicity data to identify the potential causative chemicals are unavailable. Therefore, this study aimed to (a) parameterize a physiologically-based toxicokinetic (PBTK) model for European eels to account for the impact of changes in physiology that result from sexual maturation and migration on toxicokinetics, and (b) to couple this model with a quantitative adverse outcome pathway (qAOP) for activation of the aryl hydrocarbon receptor 2 (AHR2) of fishes to predict early life stage mortality of eels as a result of exposure to maternally transferred DLCs. The PBTK model was used to kinetically predict the redistribution of DLCs within the body of female eels during migration, and ultimately the concentration in gonads and eggs. A simple qAOP was described previously linking activation of species-specific AHR2 in an in vitro luciferase reporter gene assay using transfected COS-7 cells with embryo lethality across nine species of fishes exposed to DLCs. To this end, AHR2 was cloned from European eel and used to predict eel-specific relative potencies of five DLCs representing congeners measured at among the greatest concentrations in gonads of eels. Using this data, mortality of early life stages of eels was estimated based on the internal concentrations predicted by the PBTK model. Our integrated PBTK model and qAOP approach will ultimately shed light on the question whether early life stage mortality induced by exposure to DLCs has the potential to significantly contribute to the observed decline in recruitment of eels.

## Identifying Unknown Causes of Toxicity: Proven and Innovative Methods

**TP109 Relevance of the formation of reactive electrophiles during oxidative water treatment**

*C. Prasse, Johns Hopkins University / Environmental Health and Engineering*

Oxidative treatment technologies that utilize oxidants such as hydroxyl radicals, ozone, sulfate radicals and chlorine are increasingly used in various water treatment applications, including wastewater, water reuse, drinking water and remediation of groundwater at contaminated sites. While these technologies are very effective in removing a large spectrum of organic contaminants, knowledge about the fate of these chemicals, in particular the formation of transformation products is still widely lacking. The elucidation of transformation products is further complicated by the presence a large number of natural organic compounds as these also can be precursors of toxic transformation products formed during chemical oxidation. As a result, treated waters typically contain a complex mixture of organic compounds. While modern analytical tools, in particular

high-resolution mass spectrometry, enable the detection of thousands of compounds in a single water sample, they do not provide any information about their toxicological relevance. On the contrary, in vitro or in vivo assays, which are frequently used for a toxicity assessment, provide information about the overall toxicity of a mixture while the identities of responsible toxicants remain unknown. To address this, we investigated the formation of electrophilic transformation products during oxidative water treatment by analyzing their reactions with biomolecules, in particular amino acids, peptides and proteins. Using this approach, we were able to identify a,b-unsaturated dicarbonyls such as 2-butene-1,4-dial as previously unknown transformation products that are formed during oxidation of phenols by hydroxyl radicals or chlorine. The formation of 2-butene-1,4-dial is of particular concern due to its known high mutagenicity. The used methodology thus offers a powerful approach to identify toxic transformation products that are formed during oxidative water treatment.

**TP110 Applying High Resolution Mass Spectrometry to Identify Toxic Chemicals in Wastewater Effluents**

*T.M. Young, University of California, Davis / Civil and Environmental Engineering; B.C. Jorgenson, Pacific EcoRisk; L. Wong, University of California, Davis / Civil and Environmental Engineering*

Intermittent but substantial effluent toxicity to the freshwater invertebrate *Ceriodaphnia dubia* has been experienced by a large POTW (>150 mgd) with a substantial industrial user input, with a gradient of effects typified by reversible paralysis, reproductive impairment, and mortality. Results of conventional toxicity identification evaluation (TIE) testing with *C. dubia* suggest the contaminant(s) is organic, relatively polar in nature, and possibly charged, where the unifying commonality across all effective TIE treatments is the high surface area of potentially sorptive materials. The most recent effluent toxicity episode, where only the first two of six total 24-hour effluent composite samples were chronically toxic to C. dubia, presented a unique opportunity to apply high resolution mass spectroscopy to the identification of possible contaminants. In this study, both liquid and gas chromatography quadrupole time-of-flight mass spectrometry (LC-QTOF-MS and GC-QTOF-MS) were used to quantify target compounds, screen for >5,000 suspect compounds in high resolution MS databases, and to search for unidentified ions that were correlated with the degree of toxicity observed across the sample time series. LC-QTOF-MS data were acquired in All-Ions fragmentation mode in both positive and negative electrospray ionization (ESI). LC suspects were identified using two accurate mass libraries containing pesticides, pharmaceuticals and other environmental contaminants. GC-QTOF-MS data were acquired in electron ionization (EI) mode and negative chemical ionization mode (NCI). The overall analytical workflow and data analysis approach followed methods similar to those developed by Moschet et al. (Environ. Sci. Technol., 51:1553, 2017). A total of 29 suspect compounds were detected by LC-QTOF-MS and qualified by screening against the databases and six target compounds were detected by GC-NCI. None of these compounds had a statistically significant ($p< 0.05$) linear correlation with concentration or area counts and the observed mortality or reproductive effects of that sample, suggesting that none are the primary agents of toxicity. Nontarget analysis of the LC data isolated more than 1700 compounds per sample in ESI- and over 2400 compounds per sample in ESI+. A total of 232 of these compounds were uniquely present in the samples displaying toxic outcomes. Approaches to further identify these compounds and connect them with the toxicity observed will be discussed.

**TP111 Using High Resolution Mass Spectrometry to Identify Contaminants and Sources Linked to Urban Stormwater Mortality Syndrome in Coho Salmon**

*K. Peter, Z. Tian, C. Wu, University of Washington, Tacoma / Center for Urban Waters; J. McIntyre, Washington State University; N. Scholz, NOAA Fisheries / Northwest Fisheries Science Center; E.P. Kolodziej, University of Washington, Tacoma/Seattle / Center for Urban Waters Interdisciplinary Arts and Sciences Civil and Environmental Engineering*

Urban stormwater is a major water quality threat to ecological health, causing a range of adverse, but mostly sublethal, effects in aquatic species. In western North America, untreated urban runoff induces pervasive acute mortality in adult coho salmon (*Oncorhynchus kisutch*). To better understand the relationship of this phenomenon to water quality, we applied non-target and suspect screening analyses using high resolution mass spectrometry (HRMS) to detect non-target and identified chemical features that co-occurred in sampled waters that were lethal to coho salmon in the lab and the field. Hierarchical cluster analyses were used to evaluate potential causal sources; these analyses indicated that tire wear particle (TWP) leachates were most similar to the waters that induced coho mortality, relative to other vehicular sources (e.g., motor oil, antifreeze). Among prominent detections in the mortality signature, we identified several groups of pervasive contaminants in road runoff, including polyethylene glycols (PEGs), octylphenol ethoxylates (OPEOs), polypropylene glycols (PPGs), and two groups of N-containing compounds derived from TWP. In particular, a family of (methoxymethyl) melamine compounds, previously unreported in United States surface waters, were detected in highway runoff at concentrations up to ~9 μg/L and in urban creeks at concentrations up to ~300 ng/L. Based on the prioritization of TWP as an important source in urban runoff and as relevant to the urban coho mortality syndrome, occurrence of the identified compounds and the coho mortality signature were evaluated in Puget Sound surface waters and during controlled exposures of coho salmon.

**TP112 Optimization of Sediment Toxicity Identification Evaluation Study Designs to Account for Spatial and Temporal Variability**

*D.J. Greenstein, A.N. Parks, S.M. Bay, Southern California Coastal Water Research Project / Toxicology*

Toxicity tests are an important aspect of sediment quality assessments, but knowledge of the cause of toxicity is needed to determine effective management actions. Toxicity Identification Evaluation (TIE) methods were developed to meet this need. While TIE methods manuals have detailed descriptions on performing the treatments, there is little guidance on study design, including the number of TIE samples needed to confidently make an assessment. Additionally, the level of variability associated with performing TIEs and how to account for it is not addressed. We conducted a literature survey and found that in 19 of 45 published investigations only one TIE sample was tested to determine the cause of toxicity. The goal of our study was to collect data on both the spatial and temporal variability associated with sediment TIEs using the amphipod *Eohaustorius estuarius* 10-day survival test and then use that information to make recommendations for designing future TIE studies. Ten stations were sampled in two stages at Consolidated Slip in Los Angeles Harbor, California, USA, with samples collected two months apart. In Stage I, extensive TIEs were conducted on whole sediment and pore water from three of the most toxic stations. In the Stage II, more focused TIEs were conducted on whole sediment from all ten stations. Chemical analysis for metals and a suite of organic contaminants was performed on all samples where TIEs were conducted. Using a weight of evidence approach, including TIE and chemistry analysis, it was determined that pyrethroid pesticides were the likely cause of observed toxicity at Consolidated Slip, with a lesser contribution from PAHs. Results of the 13 individual TIEs fell into three broad categories: seven TIEs where treatments for organic chemicals and specifically pyrethroids were effective; three where the treatment for pyrethroids was not effective but the treatment for organic contaminants was effective; and three where the treatment for pyrethroids was effective, but the treatment for organic contaminants was not effective. This variability was used in calculations which determined that at least three TIEs were necessary to make a confident assessment of the cause of toxicity. The results indicated that there was not substantial temporal variability in the TIE outcomes. Other recommendations are made regarding effective TIE study design.

**TP113 The Unsuccessful Toxicity Identification Evaluation**

*M.K. Chanov, EA Engineering, Science, and Technology, Inc. PBC / Ecotoxicology; M. Jirsa, J. Redifer, EA Engineering Science and Technology Inc PBC; R. Brooks, EA Engineering, Science and Technology, Inc. PBC / Toxicology Lab*

Whole Effluent Toxicity Testing (WET) can drive regulatory requirements to carry out Toxicity Identification Evaluation (TIE) testing or require a Toxicity Reduction Evaluation (TRE) on effluents not meeting permitted limits. The WET program has been successful in removing and reducing effluent toxicity through the NPDES permitting process, however, an increased number of effluents have been minimally and/or intermittently toxic. This scenario has created issues with the completion of a successful TRE program. The consequences of unidentified toxicity are uncertain treatment measures and costly and possibly endless testing to regain compliance. This presentations outlines and discusses issues and strategies that have been utilized during TRE evaluations, where difficulty identifying the causative toxicants has been encountered. The topics addressed include: non-persistent toxicity; minimal toxicity samples; and ephemeral toxicity.

**TP114 Amending the Standard Phase I Toxicity Identification Evaluation: Four Useful Additions**

*M.K. Chanov, EA Engineering, Science, and Technology, Inc. PBC / Ecotoxicology; M. Jirsa, J. Redifer, EA Engineering Science and Technology Inc PBC; R. Brooks, EA Engineering, Science and Technology, Inc. PBC / Toxicology Lab*

Wastewater treatment plant facilities that discharge unacceptable levels of toxicity must perform a Toxicity Reduction Evaluation (TRE) to identify and control the causes of toxicity. One common component of a TRE is the application of USEPA's Toxicity Identification Evaluation (TIE) procedures to identify and confirm the causes of toxicity. However, in many instances the application of the standard procedures (pH adjustment, aeration, filtration, C18 extraction, EDTA addition, sodium thiosulfate addtion, activated carbon and graduated pH) yields insufficient evidence to identify the causative toxicants associated with the wastewater. The utilization of non-standard TIE methodologies has become increasingly important as the increased efficacy of wastewater treatment has resulted in the removal of the majority of classical toxicants in industrial wastewaters, which are most commonly removed through standard TIE methodologies. This presentation provides case study evaluations of four non-standard TIE treatments: 1) Sulfamic acid (nitrite); 2) Kaolinite clay (polymers and surfactants); 3) Activated Alumina (Flouride); and 4) Ferric Chloride (Chlorite).

**TP115 Toxicity of Lead and Copper in Elevated Dissolved Organic Carbon Effluent to *Ceriodaphnia dubia***

*A.M. Briden, N. Lynch, S. Vasquez, B.C. Jorgenson, Pacific EcoRisk*

In this study we evaluate the impact of elevated dissolved organic carbon (DOC) on the acute toxicity of Pb and Cu in effluent to *Ceriodaphnia dubia*. Acute 48-hour testing with *C. dubia* was performed following standard USEPA methods. Metals concentrations were analytically verified in the test solutions to allow for determination of dissolved Pb and Cu $EC_{50}$ values. The Cu and Pb Biotic Ligand Models (BLM) were both used to calculate predicted Cu and Pb effect thresholds for comparison to the measured values generated in this study. Although the effluent DOC concentrations exceeded the upper calibration limit of the BLM, the measured and predicted effect thresholds were comparable.

**TP116 Application of Phase I and Phase II TIE Techniques in the Identification of Nickel and Vanadium Toxicity in an Industrial Effluent**

*A.M. Briden, S.L. Clark, B.C. Jorgenson, Pacific EcoRisk*

The cause of unknown chronic toxicity to *Ceriodaphnia dubia* in a limestone quarry discharge was investigated and elucidated through the execution of Phase I and Phase II toxicity identification evaluations (TIE). Initial Phase I TIE testing identified chronic toxicity associated with cationic and anionic constituents, with analytical chemistry identifying nickel (Ni) and vanadium (V) as potential causes of chronic toxicity that warranted further investigation. Phase II TIE testing employing Ni-selective sorbents, a Ni and V spiking study utilizing buffered and unbuffered laboratory water, and a synthetic effluent study all confirmed the significant contribution of Ni and V to the observed chronic toxicity. Field-based pilot scale treatment studies confirmed removal of toxicity associated with substantial reductions in Ni and V concentrations.

**TP117 Variability in Sediment Toxicity and TIE Response: An Underappreciated Contributor to Unknown Toxicity in California Bays**

*S.M. Bay, A.N. Parks, D.J. Greenstein, Southern California Coastal Water Research Project / Toxicology*

Sediment toxicity testing with amphipods and TIE characterization treatments remain the most direct and effective methods for determining the cause of sediment quality impairment in marine sediments and detecting unmeasured toxicants. However, TIE characterization treatments targeted towards nonpolar organics, metals, and ammonia occasionally fail to indicate the chemical class likely associated with the toxicity, suggesting that unmeasured contaminants or non-contaminant stressors (e.g., sediment particle size) may be the toxicant. Inability to identify the likely cause of sediment toxicity is an impediment to developing effective management and regulatory actions to improve sediment quality. Variability in sediment toxicity test responsiveness and TIE treatment performance have a strong influence on TIE results, yet TIE study designs may not allow such effects to be recognized. Recent TIE case studies from two locations in Southern California, Marina del Rey Harbor and Los Angeles Harbor, are examined to illustrate the impact of test variability on TIE interpretation. In Marina del Rey Harbor, TIE characterization treatments were unsuccessful in determining the cause of moderate levels of sediment toxicity. Furthermore, sediment toxicity disappeared at the stations over a six-month period, even though there were no changes in sediment concentrations of priority pollutants and current use pesticides. In Los Angeles Harbor, multiple stations with high sediment toxicity were characterized using TIE treatments that included addition of charcoal, cation exchange resin, zeolite, and PBO. Sediment chemistry and spatial analysis indicated that all test sites had similar contamination profiles and that pyrethroid pesticides were causing toxicity at each site. However, effectiveness of the charcoal and PBO treatments varied among sites, leading to potentially different conclusions regarding the cause of toxicity at individual stations. Recommendations for improvements to TIE experimental designs and quality assurance practices, as well as new methods with greater sensitivity and specificity, are suggested that will help maintain the value of TIEs for sediment quality assessment.

**TP118 Effects of glyphosate on the cell population growth of the green algae *Selenastrum capricornutum*, and removal of toxicity with TIE treatments**

*A. Cibor, Enthalpy Analytical / Aquatic Toxicology; K.M. Payne, P. Arth, Enthalpy Analytical / Nautilus Environmental / Aquatic Toxicology*

Cell population growth of the freshwater aquatic green algae *Selenastrum capricornutum*, a common monitoring species for toxicity testing, can be affected by the practice of spraying herbicides near potential points of sample collection. This can include treatment settling ponds, WWTP effluent discharge/sampling points, urban storm water outfalls, and natural receiving waters. Many of these water bodies are subject to NPDES permit monitoring, and introduction of these herbicides (especially outside of a wastewater treatment process that would remove them) may have an impact on compliance results reported to regulatory agencies. Often these herbicides can be introduced by processes that are outside of the control of responsible parties. This presentation explores three primary objectives: 1) establishing baseline toxicity data for glyphosate effect levels, 2) assessing if those levels could potentially be observed in an effluent or receiving water sample, and 3) finding effective toxicity identification evaluation (TIE) treatments for glyphosate-related toxicity. Spiking studies using glyphosate, a common ingredient used in many weed killers found in most home improvement or hardware stores, were conducted to determine effect concentrations in green algae. Once effect concentrations were established, an evaluation of TIE treatments was conducted on the glyphosate-spiked samples in order to identify a single treatment or combination of treatments that would effectively remove the toxicity. 96-hour growth tests were conducted according to EPA 2002 freshwater chronic test methods (EPA-821-R-02-013). Additionally, an evaluation was performed to determine the persistence of the observed toxic effect in an effort to identify whether a TIE could be effectively performed within a reasonable timeframe after initial toxicity was detected. Finally, studies were conducted to establish if, when applied according to manufacturer specifications, glyphosate could be measured in quantities high enough to elicit a toxic response in the green algae test.

## Interpreting Biological Effects of Metals and Their Mixtures in the Aquatic and Terrestrial Environments

### TP119 Aluminum and Acetylcholinesterase in Honey Bees: Understanding Interactions Using Behavioral and Biochemical Data

*A. Chicas-Mosier, Oklahoma State University / Integrative Biology; L.P. Belzunces, INRA / Abeilles & Environnement; T.E. Black, C.I. Abramson, Oklahoma State University / Psychology*

Aluminum is increasingly globally bioavailable with acidification from warming and poor mining practices. This bioavailability has been shown to increase uptake by flora that can then be dispersed through products such as fruit, pollen, and nectar. Concentrations of aluminum in fruit and pollen in North America have been reported between 0.05 and 670mg/L. This is particularly concerning for pollinators that ingest pollen and nectar. Honey bees represent a globally present species experiencing decline in Europe and North America. Region specific decline may be a result of differential toxicity of toxicant ingestion by subspecies. Previous literature suggests that aluminum binds to acetylcholinesterase and limits the protein's activity. We have previously shown that low concentrations of ingested aluminum may temporarily increase activity and decreases circadian rhythmicity and lifespan, but that these effects are partially dependent on subspecies. These data also suggest a possible hormetic effect of aluminum in honey bees that warrants further study at intermediate doses. The behavioral and mortality results corroborate the cholinergic hypothesis however this analysis has not been previously conducted in honey bees. We conducted a cholinergic enzyme analysis in the form of a modified Ellman assay on *Apis mellifera mellifera* heads. We exposed live bees to various concentrations of aluminum in sucrose solution for up to 48 hours before analysis. We expect that exposure to aluminum will decrease enzyme activity which will confirm the cholinergic aluminum hypothesis in honey bees.

### TP120 Assessing effects of copper and zinc mixtures on larval development rates of the Mediterranean mussel (*Mytilus galloprovincialis*)

*E. Green, R. Tolliver, Enthalpy Analytical / Nautilus Environmental; A. Cibor, Enthalpy Analytical / Aquatic Toxicology; J. Goyette, Enthalpy Analytical / Analytical Chemistry*

Commercial and recreational boat hull anti-fouling paints often contain a variety of different metals which can have detrimental effects on marine organisms in harbors and marinas. While copper is still a common and effective ingredient in most hull anti-fouling paints, concerns about copper toxicity have led to an increase in low-copper or non-copper paints that may use zinc as an alternative. Whole Effluent Toxicity (WET) testing has been used as part of the evaluation framework to determine water quality criteria for contaminants of concern such as metals. However, because marine organisms are likely to be exposed to multiple metals, particularly where anti-fouling paint in present, there has been increased interest in understanding the combination effects of metals. Exposure to combinations of metals can potentially yield different effects than those observed when an organism is exposed to a single metal. Mixtures can lead to a variety of responses such as additive, synergistic, or deleterious effects, and understanding these interactions at the species-specific level can provide valuable information for decision makers. While there have been many previous studies examining the effects of copper on mussel development, fewer have focused on zinc and copper mixtures. Bivalves are of particular interest as they are both a target organism for anti-fouling paints as well as a common monitoring species used to evaluate ambient water quality in harbors and marinas. This study investigates the combined effects of copper and zinc on the embryo-larval development of the Mediterranean mussel (*Mytilus galloprovincialis*) using published EPA methods. Environmentally relevant levels were evaluated, with many of them representing measured concentrations in previously tested ambient samples. Observed responses for the various ratios of combined copper and zinc exposures were evaluated against effect levels for the individual metals. This study highlights the importance of considering effects of metals mixtures when determining site-specific criteria for individual water bodies.

### TP121 Comparison of the ecotoxicological effects on aquatic organisms of the last two spills related to iron mining in Brazil

*T. Furley, L.B. Mendes, APLYSIA Environmental Research and Solutions; K. Chagas, Aplysia Soluções ambientais / TÉCNICO; B. Horvath Vieira, R. Mendes, APLYSIA Environmental Research and Solutions; T. Ulhoa, G. Oliveira, Anglo American; R. Campelo, L.C. Medeiros, RENOVA Foundation; F. Aquinoga de Mello, APLYSIA Environmental Research and Solutions*

In the last 3 years, 2 spills related to iron mining occurred in Brazil. In November 2015, with the rupture of the Fundão dam in Mariana/MG, about 50 million m³ of tailing traveled 650 km in the Doce River watershed towards the ocean. In March 2018, with a pipeline spill, around 500 tons of iron ore reached Santo Antônio do Grama stream (MG), and the plume traveled 21 km until the confluence with Casca river. Among possible environmental alterations in such events, the chemical contamination by the main constituents of the ore or tailing, iron and manganese (APLYSIA, 2015; GOLDER, 2016) and the impact associated of the input of solids in the water are highlighted. Indicators based on effetcs were used in both spills to evaluate the possible impact to the aquatic organisms. Standardized assays were conducted, according to technical regulations, with organisms of 3 different trophic levels: the fish *Danio rerio*, the microcrustaceans *Daphnia silimis* and *Ceriodaphnia dubia*, and the bacteria *Vibrio fisheri*. In the first event, 1048 results were gathered, collected in 45 sites from November 2015 to January 2016; in the second event, 482 results were obtained in 17 sites from March to April 2018. In the 2015 spill, 98.75% of the acute assays indicated an absence of toxicity, but 77.89% of chronic assays (*C. dubia*) indicated presence of toxicity. The samples with toxicity coincided with the moment of passage of the tailings plume, indicating that such impact may be associated to the physical effects of suspended solids (MELLO et al, 2017). In the 2018 event, 100% acute effects absence and 48.48% chronic ecotoxicity presence for *C. dubia* were observed. It was verified a spatial relation between the toxic results and the sites under greater influence of the spill, mainly due to removal of the material. The relation with the suspended particles was observed during moments of intense precipitation, when toxic effects were registered including sites with no influence of the spill (MELLO et al, 2018). *C. dubia*, a filter organism, is affected by concentrations of suspended particles due to obstruction of their feeding structures, which affects the growth rate and promote stress to the organism (HYNES, 1970). In the end, despite the events of distinct dimensions, the same response patterns were observed: absence of acute ecotoxicity and presence of chronic ecotoxicity for *C. dubia*, mainly related to the concentrations of suspended solids on the water.

**TP122 Metal Mixture Toxicity and Accumulation in Lettuce Seedlings**

*I. Moran, M.M. Bee, C. Charlton, A.M. Smith, E.J. Kramarevsky, Western Washington University; E.J. Lawrence, Western Washington University / Institute of Environmental Toxicology; T. Norris, Western Washington University; R.M. Sofield, Western Washington University / Department of Environmental Sciences*

Many toxicants are found in the environment as mixtures but because toxicants are routinely tested individually, mixture effects are poorly understood. Understanding the biological effects of realistic exposures, like mixtures, is essential to managing environmental contamination. In this study we explored how the presence of one metal affects the bioavailability and toxicity of a second metal when present in tandem. In addition to toxicity testing, we measured accumulated concentrations of metals in exposed lettuce seedlings. This data could be used within the tissue-residue approach (TRA) for toxicity assessment, which uses internal tissue concentrations as a dose metric rather than ambient aqueous concentrations. This approach removes exposure variability and allows for more accurate prediction of toxicity under expected environmental conditions. For this experiment we conducted acute toxicity tests with lettuce seedlings exposed to binary metal mixtures and used growth inhibition as the effect endpoint. The first step was to determine the tissue accumulation and toxicity of single metals (Al, Cu, Cd, Fe, Zn). Next, we exposed seedlings to all combinations of binary mixtures and measured growth inhibition and bioaccumulation of metals. We used toxic units and the Isobole approach to classify the mixture effects as additive, synergistic or antagonistic. The toxicity results using nominal concentrations have shown antagonistic interactions for all mixtures tested, except Fe and Cu. The tissue concentration data collection is on-going and results will be presented. Primarily applied to organic mixtures, experimental studies that utilize the TRA approach to describe metal mixture toxicity are rare. This work improves our understanding of mixture effects and bioavailability and is critical to predicting toxicity of metals in the environment under expected environmental conditions.

**TP123 The Trouble with Toxic Units**

*E.M. Traudt, Jacobs / Department of Chemistry; S.A. Roark, Jacobs / Environmental & Nuclear*

Risk assessments conducted on chemical mixtures under the assumption of additivity have the potential to underestimate or overestimate risk depending on the slopes of concentration-response relationships for each chemical. Chemical mixtures occur ubiquitously in the environment and are a growing concern amongst various governmental and private sector industries. Due to the complexity of many of the naturally occurring mixtures, mixture toxicity is generally poorly characterized. One method of standardizing multi-chemical toxicity is known as the toxic unit (TU) approach, where a TU is defined as the ratio of the concentration of a given chemical in a mixture to the concentration that would elicit toxicity in 50% of a population (EC50). Because the toxicity of different chemicals can vary widely on a mass basis, a TU can be a powerful tool to standardize the metric of toxicity between multiple chemicals, and in the concentration-addition (CA) model, the sum of TUs from multiple chemicals can be used to generate a mixture toxicity prediction. In many systems, however, chemical concentrations occur well below the EC50, and because calculation of a TU does not consider the slope of the concentration-response relationship, it becomes nearly impossible to determine the effect level from TUs. For instance, a TU = 0.5 for a chemical with a shallow dose-response curve will exhibit higher toxicity than a chemical with a steep dose-response relationship. For this reason, the CA model is primarily recommended for chemicals with similar concentration-response slopes. The goal of this study is to quantify how differences in individual-chemical concentration-response curves affect predicted mixture TUs. For the analysis, mixture TU predictions were generated from binary combinations of simulated dose-response curves with (1) both having shallow slopes, (2) both having steep slopes, and (3) one steep slope and one shallow slope. Next, mixtures containing more than two chemicals were evaluated in relation to the binary results to determine if the addition of more chemicals with either the same or different slopes compounded or mitigated the differences in the predicted mixture toxicity. Finally, these results were compared to the independent-action model predictions to draw conclusions with respect to the applicability of the different additivity models.

## Micro-organisms and Biopesticides in Crop Production: Use and Environmental Safety Considerations

**TP124 Current environmental regulations might not protect against non-targeted effects of microbial pesticides: The case of Dipel and Daphnia**

*A. de Souza Machado, Freie Universität Berlin / Institute of Biology; C. Zarfl, Eberhard Karls Universität Tübingen / Center for Applied Geoscience; W. Kloas, Leibniz-Institute of Freshwater Ecology and Inland Fisheries*

Currently, there is a trend toward an increasing use of biopesticides assumed to be environmentally friendly, such as *Bacillus thuringiensis* (Bt). Nonetheless, the introduction of microorganisms as prospective contaminants might add environmental risks and uncertainty as these organisms likely respond to environmental cues different from inanimate matter. For instance, studies of the Bt toxicity to nontarget organisms have reported low effects at high exposure levels, which is interpreted as indicating negligible risk to nontarget organisms. To test whether the Bt-based biopesticide DiPel ES fulfilled the core ecotoxicological assumption of monotonicity (e.g. toxicity increasing with increased contaminant exposure), we investigated the response of the nontarget organism *Daphnia magna* to waterborne DiPel ES, a globally used Bt formulation. Neonates and adults were exposed for 48 h to more than 25 concentrations covering more than 4 orders of magnitude. Immobilization and mortality were monitored in more than 1000 organisms (567 neonates and 578 adults), representing the largest single study of Bt nontarget toxicity. Whole body biomarkers (body weight, protein, chitobiase, catalase, xenobiotic metabolism, and acetylcholinesterase) were measured in the adults. The high concentrations of this biopesticide did not cause significant effects, however low doses did elicit high toxicity. In other words, the immobilization and mortality of the neonates were affected in a nonmonotonic and inverted U-shaped pattern with $EC50_s$ that were ~$10^5$-fold lower than those reported by the manufacturer. The immobilization of adults demonstrated a similar pattern. The biomarker results revealed multiphasic dose-response curves, which suggested toxicity mechanisms that affected various physiological pathways. The main particle size in exposure media was in the size range of bacterial spores and crystal toxins. However, the chemical heterogeneity was nonmonotonic, with a change in the phase at the maximum of toxicity (~5 $\mu L\ L^{-1}$), which might explain the observed nonmonotonic effects. These results demonstrate the vulnerability of a nontarget organism to a biopesticide that is considered to be safe, while challenging the applicability of the central ecotoxicological assumption of monotonicity. In this sense, microorganisms may differ from traditional agrichemical contaminants, thus requiring new ecotoxicological frameworks for proper regulation.

**TP125 Environmental Safety Assessment for Agricultural Uses of Lipochitoligosaccharides as Plant Growth Regulators**

*A. Tompsett-Higley, Bayer Crop Science / Regulatory Sciences; J. Sherman, Celanese Corporation; A.M. Adio, M.S. Bleeke, K.M. Huizinga, P. Sudarsanam, Monsanto Company; L. Schuler, Monsanto Company / Regulatory Sciences*

Lipochitooligosaccharides (LCOs) are molecular signaling molecules involved in plant-microbe symbioses, including rhizobial nodulation by bacteria and arbuscular mycorrhization by fungi. The bacteria and fungi involved in these natural processes produce a wide variety of LCO molecules, but they act via the same receptor-mediated processes in plants. LCO signaling progresses via the DMI (doesn't make infections) pathway and can result in nodulation, root branching, and mycorrhization. Biological agricultural products developed in collaboration between Monsanto and Novozymes capitalize on the ability of LCO molecules to enhance plant health. To support registration of products containing LCO SP104 and LCO MOR116 in the United States, the environmental safety of these two LCO molecules was evaluated through nontarget organism studies performed according to US Environmental Protection Agency guidelines. Taxa evaluated included mammals, birds, fish, aquatic invertebrates, insects, and plants. In acute toxicity tests, LCO SP104 and LCO MOR116 were found to be practically nontoxic to all tested taxa. LCO SP104 did not have adverse effects on plants, even at concentrations above the maximum label rate. Considering the low use rates of agricultural products containing LCO SP104 and LCO MOR116, maximum predicted exposures to LCOs are orders of magnitude less than those evaluated in the nontarget organism studies. Additionally, animals and plants have a history of safe exposure to LCOs originating from the rhizosphere, and LCOs degrade into molecules that are essentially nontoxic, such as chitin and vaccenic acid. For these reasons, the potential for risk to nontarget organisms from agricultural uses of LCO molecules is negligible.

## Incorporating Effect-Based Molecular Assays in Environmental Monitoring and Risk Assessment

**TP126 Evaluating the Effectiveness of Advanced Oxidation Processes at Reducing AhR, ER, and p53 activity via In vitro Cell Bioassays**

*G. Harraka, University of California, Riverside; S.L. Coffin, University of California, Riverside / Environmental Toxicology; E.G. Xu, University of California, Riverside; K. Cochran, University of South Carolina / Department of Chemistry and Biochemistry; S.D. Richardson, University of South Carolina; D. Schlenk, University of California, Riverside / Department of Enviromental Sciences*

Persistence of emerging compounds in wastewater effluent is a concern that has received increasing research interest over the past decade particularly in water scarce regions such as California. As sources of recycled water have been increasing, it is imperative to develop methods that can evaluate the safety of recycled water and the treatment processes used to enhance water supplies. To analyze the effectiveness of water treatments, in vitro cell bioassays were performed using water samples taken from the different stages and types of treatment. Secondary effluents were chlorinated, chlorinated and brominated (C+B), or nonhalogenated (control). The treatment train also utilized different advanced oxidation processes (AOPs), including microfiltration and reverse osmosis. Nonhalogenated samples were found to elicit significant receptor activity in both the p53 and ER assays. Chlorination reduced estrogenicity in general, with statistically significant reductions in receptor activity for the microfiltration treatment process. In addition, C+B was found to be effective at reducing p53 activity in the UVA/OP and reverse osmosis samples. While not below detection limits, this AOP also proved to be more effective at reducing p53 activity in secondary effluent and untreated Santa Ana River water. AhR activity for all samples was found to be insignificant. These results are important for evaluating the potential impacts of recycled water.

**TP127 Pollutant-Induced Changes in Ca2+ Channels Alter DREAM-Mediated Gene Transcription**

*N. Schuko, California State University, Long Beach / Biology; E.B. Holland, California State University, Long Beach / Biological Sciences*

Several environmental pollutants, including polychlorinated biphenyl (PCB) congeners and triclosan, are capable of causing $Ca^{2+}$ signal disruption (CSD) by altering the activity of the ryanodine receptor (RyR) or the L-type voltage gated $Ca^{2+}$ channel (CaV1). These two channels are important to countless physiological processes, but the extent to which CSD through these channels contributes to altered cellular pathways is currently unclear. We investigated whether CSD, caused by cellular exposure to PCBs and triclosan, alters gene transcription as regulated by the $Ca^{2+}$-sensitive transcriptional repressor DREAM (downstream regulator element antagonistic modulator). When intracellular $Ca^{2+}$ concentrations are decreased, DREAM remains bound to DNA and represses transcription, and at high intracellular $Ca^{2+}$ concentrations, DREAM is released from DNA and activates transcription, representing a direct connection between CSD and transcription. We utilized the GT1-7 hypothalamic and the TαT1 thyrotrophic cell lines to measure whether CSD alters transcription of gonadotropin releasing hormone (GnRH), thyroid stimulating hormone (TSH), neuronal PAS domain protein 4 (NPAS4) and brain-derived neurotrophic factor (BDNF). Cells were exposed to varying concentrations of each pollutant for multiple time periods and GnRH, TSH, NPAS4, and BDNF levels assessed using qPCR. GT1-7 cells exposed to the potent RyR activator PCB 95 did not lead to changes in GnRH mRNA expression consistent with low basal RyR gene expression. Exposure of GT1-7 cells to triclosan, a CaV1 inhibitor, significantly decreased GnRH transcription in a concentration and time dependent manner. Exposure of TαT1 cells to PCB95. a RyR activator, showed no significant changes in TSH, and beginning analysis of NPAS4 and BDNF transcription levels are trending upward. Small interfering RNA (siRNA) knockdown followed by DREAM rescue experiments are currently being conducted. DREAM is important to proper functionality of the digestive system, central nervous system, and skeletal and cardiac muscle, and it has been tied to pain reception, learning and memory and thyroid-gland health. This work will help address whether CSD is contributing to such alterations by altering DREAM-mediated transcription.

**TP128 Screening of neurodevelopmental toxicity of nanomaterials : Embryonic stem cell, neural stem cell and zebrafish study**

*J. Im, University of Seoul; J. Choi, University of Seoul / School of Environmental Engineering*

Neurotoxicity and developmental toxicity of nanomaterials have been previously reported. However, neurodevelopmental toxicity of nanomaterials has still been poorly understood. In this study, to elucidate neurodevelopmental toxicity due to exposure of nanomaterials, we investigated developmental toxicity of nanomaterials using zebrafish embryos (in vivo) and embryonic stem cells (in vitro) and neurodevelopmental toxicity of nanomaterials using neural stem cells (in vitro). Various nanomaterials, such as, silver nanoparticles, $SiO_2$, MWCNT and graphenes were screened using these in vitro and in vivo models. The preliminary results suggests possible involvement of nanomaterials on neurodevelopmental processes. Our result also suggests multi-model approach could complement the limitations of a stand-alone model organism and thus more accurately identify hazard of nanomaterials. Acknowledgement : This research was supported by Nano Material Technology Development Program through the National Research Foundation of Korea(NRF) funded by Ministry of Science and ICT (2014M3A7B6020163).

**TP129 Contaminant body burdens and molecular responses associated with dietary exposure to mercury and POPs in the little skate (*Leucoraja erinacea*)**

*L. Crawford, Stony Brook University; G. Paterson, Michigan Technological University; N. Dheilly, C. Lee, N.S. Fisher, J. Olin, A. McElroy, Stony Brook University / School of Marine & Atmospheric Sciences*

Elasmobranchs are globally threatened by environmental stressors due to their life histories as long-lived, slow-growing apex predators with slow maturation and low fecundity. Over-harvesting is recognized as a major threat, but given life-history considerations, elasmobranchs may be at additional risk from exposure to contaminants including mercury and persistent organic pollutants (POPs) such as PCBs and other halogenated organic compounds. Contaminant bioaccumulation and potentially negative consequences of their accumulation in elasmobranchs is understudied, with relatively little published work available on only a few species. In order to address this issue, we conducted a pilot study to examine contaminant bioaccumulation and cellular responses in juvenile little skates (*Leucoraja erinacea*) exposed to a diet rich in POPs. Two groups of little skates were exposed to a sushi-grade tuna diet high in methyl mercury and POPs or a reference diet of farmed salmon known to be low in POPs. After 20 days of dietary exposure, muscle and liver tissue were harvested from the skates. Mercury levels measured in liver and muscle tissue were several times higher in tuna-fed skates ($Hg_{liver}$=0.711 mg/g d.w., $Hg_{Muscle}$=0.707 mg/g d.w.) than salmon-fed skates ($Hg_{liver}$=0.251 mg/g d.w., $Hg_{Muscle}$=0.185 mg/g d.w.), and a significant correlation was observed between Hg levels in muscle and liver tissue on an individual basis ($R^2$= 0.838, p= 0.00141). We are in the process of analyzing diet and tissue samples for a suite of POPs including 41 PCB congeners and 19 organochlorine compounds. If similar correlations are observed with other POPs, this would support the utility of using non-destructively collected muscle biopsies to evaluate POP body burdens in wild-caught organisms. Additionally, we will be using quantitative PCR to evaluate differential RNA expression of a suite of transcripts known to be associated with POP exposure and effects to determine if important cellular systems may have been modified by the relatively natural exposure modeled in this experiment. Targeted transcripts include glutathione-*S*-transferase (GST), metallothionein (MT), heat shock protein 70 (HSP70), and CYP1A. This study will be one of the first to compare bioaccumulation and cellular response in elasmobranchs under controlled exposures and will support future work with additional wild caught species examining the impact of bioaccumulative chemical stressors on elasmobranch cellular systems.

**TP130 RNA-sequencing analyses to better understand how temperature or parasitic infection modulates cadmium toxicity in rainbow trout (*Oncorhynchus mykiss*)**

*M. Defo, Environment and Climate Change Canada; A.D. Gendron, T.L. Colson, Environment and Climate Change Canada / Aquatic Contaminants Research Division / Water Science and Technology; M. Pilote, P. Turcotte, M. Houde, Environment and Climate Change Canada / Aquatic Contaminants Research Division*

The simultaneous presence of natural and anthropogenic stressors in aquatic ecosystems can challenge the identification of factors causing declines in fish populations. These stressors may include chemical mixture and the potential interactions with environmental factors, such as water temperature and parasitism. The stressor-stressor interactions may vary from antagonism to synergism resulting in environmental risks at the organismal or population level not predicted by exposure to individual stressor. This study aimed to evaluate the combined effects of cadmium (Cd) and elevated water temperature or parasite infection in juvenile rainbow trout (*O. mykiss*). Fish were exposed to diet borne Cd (6 µg Cd/g wet feed), individually and in combination with thermal (23°C) or parasitic stress, for 28 days. The parasite challenge consisted of a single exposure to glochidia (larvae) of the freshwater mussel *Strophitus undulatus* which encyst in fish tissues. Results indicated lower fish length, weight, and relative growth rate in fish exposed to the elevated water temperature condition. Body condition and hepato-somatic index of fish were, however, higher in this temperature treatment compared to other groups. Hepatic Cd concentrations were 10-fold higher in trout fed with the metal-contaminated diet; exposure to thermal stress or parasitism did not influence tissue Cd bioaccumulation. More than 700 genes were differentially transcribed in fish exposed to the individual heat stress treatment, however, Cd exposure nor parasite infection did not affect the number of differentially transcribed genes, compare to controls. The highest number of differentially transcribed genes (969 genes) was observed in trout exposed to combined Cd and high temperature stressors. Only 40 genes were differentially transcribed when fish were exposed to Cd and glochidia. These results suggest that dietary Cd may exacerbate the water temperature stress and to lesser extend parasitic infection stress on trout transcriptomic responses. Genes involved in stress response, protein folding, angiogenesis, apoptosis and immune system were upregulated in fish exposed to Cd and heat, and genes involved in calcium, glucose and cholecalciferol metabolisms were downregulated. Biomarker analyses will be conducted to complement transcription analyses. This study may help identify stressor-response relationships in freshwater fish and potentially benefit to the environmental risk assessment and management.

**TP131 Marine sentinel species biomonitoring with gene expression: Comparing contaminant burdens and gene expression among bird breeding colonies**

*M. King, Simon Fraser University / Biological Sciences; J.E. Elliott, Environment and Climate Change Canada / Science and Technology Branch Ecotoxicology and Wildlife Health Division; D. Crump, Environment and Climate Change Canada / National Wildlife Research Centre; V. Marlatt, T.D. Williams, Simon Fraser University / Department of Biological Sciences*

Persistent contaminants can bioaccumulate in marine birds, potentially causing injury or even mortality at higher levels of exposure. Additionally, the potential for catastrophic environmental disasters, for example, petroleum spills due to vessel traffic and bitumen transport in the eastern North Pacific Ocean, underscores the need to collect baseline tissue-contaminant data and improve wildlife injury assessment capabilities. Using avian sentinel species for continental shelf and nearshore habitats, the rhinoceros auklet and double-crested cormorant, respectively, we aim to demonstrate the utility of a gene expression-based approach for linking contaminant burdens to transcript-level perturbations among breeding colonies, and potentially individuals. Ongoing research using eggs collected at breeding colonies quantified a range of persistent organic pollutants, polycyclic aromatic hydrocarbons, and mercury in developing embryos. We also measured the relative expression of ≥27 genes involved in a variety of pathways such as xenobiotic and lipid metabolism, immune function, and oxidative stress response in embryonic liver tissue using species-specific PCR arrays. Thus, this comparison of contaminant concentrations in sentinel species among colonies coupled with gene expression should improve our understanding of contaminant effects in sentinel marine wildlife, while also evaluating the utility of individual genes or suites of genes as a biomarker of contaminant burdens in wild avian species.

**TP132 Characterizing changes in molecular toxicity pathways to predict adverse outcomes of fluoxetine in adult fathead minnows**

*C. Colville, S. Malala Irugal Bandaralage, University of Saskatchewan; U. Fuchylo, A. Alcaraz, University of Saskatchewan / Toxicology Centre; C. Grimard, S. Wood, University of Saskatchewan; M. Brinkmann, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre; A. Masse, University of Saskatchewan / Toxicology Centre; D. Crump, Environment and Climate Change Canada / National Wildlife Research Centre; N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences; N.S. Hogan, University of Saskatchewan / Department of Animal and Poultry Science and Toxicology Centre; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre*

Pharmaceuticals and Personal Care Products have become a major threat to aquatic environments due to their toxicity to non-target organisms and constant discharge into surface water systems. Fluoxetine (FLX) is the most common selective serotonin reuptake inhibitor pharmaceutical used for the treatment of psychological disorders such as depression. Increased prescription use of FLX by human populations has lead to its pseudo-persistence in effluent-receiving waterways. However, there is currently limited information on chronic, low-level exposure effects of FLX in fish. In particular, little is known about its specific mechanism of action and the associated toxicity pathway(s) in fish. This information is important for predicting apical responses to FLX. Therefore, the main goal of this study is to identify and validate key molecular toxicity pathways that are predictive of apical endpoints induced by exposure to FLX using a model species common to North American freshwater systems, namely the fathead minnows (*Pimephales promelas*). This will be accomplished by exposing adult fathead minnows to a range of three concentrations of FLX in a flow-through system for an exposure period of 21 days. After 96 h a subset of samples will be collected to characterize molecular toxicity pathways using whole transcriptome, whole proteome and targeted metabolome analyses. In addition, over the 21-day course of the experiment individuals will be assessed for behavioural changes, morphometrics, fecundity, and altered secondary sex characteristics, and these physiological outcomes will be correlated with early molecular response patterns to establish molecular toxicity pathways that can be used to predict apical outcomes in addition to a better understanding of environmental relevance of FLX. This study is part of the EcoToxChip project (@ecotoxchip).

**TP133 Characterizing changes in molecular toxicity pathways to predict adverse outcomes of 17β-trenbolone in adult fathead minnows (*Pimephales promelas*)**

*S.H. Malala Irugal Bandaralage, University of Saskatchewan / Toxicology Centre; C. Colville, University of Saskatchewan; U. Fuchylo, University of Saskatchewan / Toxicology Centre; C. Grimard, University of Saskatchewan; A. Alcaraz, University of Saskatchewan / Toxicology Centre; M. Brinkmann, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre; A. Masse, University of Saskatchewan / Toxicology Centre; D. Crump, Environment and Climate Change Canada / National Wildlife Research Centre; N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences; N.S. Hogan, University of Saskatchewan / Department of Animal and Poultry Science and Toxicology Centre; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre*

Metabolites of synthetic steroids that are used in livestock production as growth promoters often are released into surface waters, inadvertently exposing and potentially causing adverse effects to aquatic wildlife. One such steroid is trenbolone acetate, an anabolic steroid used as a growth promoter in beef cattle. Trenbolone acetate is hydrolyzed in the blood into its active form 17β-trenbolone, which acts as an agonist to the androgen receptor. Significant concentrations of 17β-trenbolone are excreted through manure, which can result in exposure of aquatic life such as fish through runoff from feedlots or during field fertilization using manure. Current research suggests 17β-trenbolone impacts reproduction of vertebrates including fish by acting as a potent androgen, thereby decreasing fecundity, altering plasma steroids and changing phenotype. The purpose of this study is to further our knowledge regarding the specific toxicity pathways of trenbolone by identifying key molecular response patterns that may be altered during exposure to 17β-trenbolone in adult fathead minnows (*Pimephales promelas*), and to link these with apical outcomes of regulatory relevance. Specifically, this study will expose male and female adult fathead minnows to 17β-trenbolone for 21d in a flow-through system. Samples will be collected after 4 and 21 days, and will be subjected to 'omics (transcriptomics, metabolomics, proteomics) and apical outcomes (histology, meristic parameters, growth, fecundity, secondary sex characteristics, behaviour) analyses, respectively. We predict this research will identify critical biological endpoints and pathways, which could be utilized to predict apical outcomes across different species and chemicals acting through a similar mechanism of action (i.e. androgens). This study is part of the EcoToxChip project (@ecotoxchip).

**TP134 Time-course *Daphnia magna* metabolomics as a new water quality monitoring tool**

*T. Jeong, M.J. Simpson, University of Toronto, Scarborough / Department of Physical and Environmental Sciences*

Environmental monitoring which is essential for environmental decision making has utilized various biological parameters of aquatic species for assessing water quality. The *Daphnia magna* metabolome has been suggested as a potential tool for examining biomarkers of environmental stresses; however, studies for applications in biomonitoring and understanding on dynamics of metabolomic regulation have not been examined in detail. In this study, time-course *D. magna* metabolomics was applied to better understand metabolomic regulation in ambient (non-stressed) conditions. Additionally, to investigate how sensitive and how informative the *D. magna* metabolome in response to aquatic stresses, *D. magna* was exposed to stressful conditions over time. Metabolites reported and annotated by previous studies were selected and the targeted metabolites were quantified using liquid chromatography with tandem mass spectrometry (LC-MS/MS). Under ambient conditions, metabolomic regulation in different development stages, reproduction stages, days and hours were observed. Under stressful conditions, *D. magna* metabolome was monitored in starvation and sub-lethal exposure to a pharmaceutical ingredient and endocrine disruptor. Metabolite dependent periodicity and stability were observed under ambient conditions. Hourly monitoring results indicate the time-dependent metabolomic regulation was tightly organized between individuals. Under stressful conditions, it was revealed that the homeostasis of *D. magna* is highly vulnerable to the exogenous stressors. Additionally, abnormal regulation of *D. magna* metabolome provied mechanistic insights due to changes in water quality. This study demonstrates a strategy to use *D. magna* metabolomics in water quality monitoring and highlights the utility and potential of the time-course metabolomics approach.

## A Celebration of Whole Ecosystem Experiments

**TP135 Accumulation of Silver in Yellow Perch (*Perca flavescens*) and Northern Pike (*Esox lucius*) From a Lake Dosed with Nanosilver**

*C.D. Metcalfe, Trent University / Water Quality Centre; J.W. Martin, University of Alberta / Department of Environmental Science and Analytical Chemistry; L. Hayhurst, M. Rennie, Lakehead University*

A total of 15 kg of silver nanoparticles (AgNPs) was added continuously over two ice-free field seasons in 2014 and 2015 to a boreal lake (i.e. Lake 222) at the IISD-Experimental Lakes Area in Canada. We monitored the accumulation of silver (Ag) in the tissues of yellow perch (*Perca flavescens*) and northern pike (*Esox lucius*) exposed to the AgNPs under environmentally relevant conditions. The greatest accumulation was observed in the liver tissues of pike, and a single pike sampled in the second year of additions had the highest concentration observed in liver of 5.1 µg/g wet weight. However, the Ag concentrations in gill and muscle tissue of both pike and perch did not exceed 350 ng/g. Following additions of AgNP, the Ag residues in fish tissues declined, with a half-life of Ag in pike liver of 119 days. Monitoring using passive sampling devices and single particle ICP-MS during the AgNP addition phase confirmed that Ag nanoparticles were present in the water column and estimated mean concentrations of Ag increased over time to a maximum of 11.5 µg/L. These data indicate that both a forage fish and a piscivorous fish accumulated Ag in a natural lake ecosystem dosed with AgNPs, leading to Ag concentrations in some tissues of the piscivorous species that were 3 orders of magnitude greater than the concentrations in the water. There was evidence of oxidative stress in both perch and pike as a result of exposure to AgNPs.

**TP136 Drone Imagery as a Useful Tool to Survey a Wetland Habitat**

*M.M. Valentine, L.B. Martello, S.J. Luis, Ramboll*

Drone technology was used at a site where investigations from ten years prior identified an endangered species of freshwater shrimp in small, shallow ponds in remote areas across the site. Surveying the site to find these small ponds on foot would be time consuming and difficult given the saturated soil and high, dense vegetation. Also, the likelihood of missing a pond containing shrimp was high given the difficulty of navigating the terrain on foot. Therefore, the use of a drone to identify low lying areas across the site where habitat could support this species of shrimp expedited field efforts. The drone allowed for the identification of vegetation specific to the ponding areas. High-resolution RGB drone imagery was run through supervised and unsupervised image classification with varying numbers of training samples. Image classification results were manually inspected for correctness and compiled to identify the best areas for field biologists to focus their survey. Image classification is effective and relatively quick to process, and provides a means of collecting data efficiently over expansive areas. Drones are also useful when surveying sites where access on foot is problematic such as swamps/marshes, waterways, cliffs, and intertidal habitats that occur intermittently over vast stretches of coastline. Drones are also ideal for identifying habitats with populations of sensitive fauna, such as birds, where disturbance is preferentially minimized. Software is available that allows overlapping aerial photographs to be joined together to create an ortho-rectified photo mosaic. The processing power of some software packages is very sophisticated, allowing three dimensional images to be created using information embedded in aerial images collected using drones. The three-dimensional image can be used to visualize a target whether it is a landform such as a rock outcropping, a water feature, or a nesting area.

**TP137 Ecological Factors Controlling Insect-Mediated Methylmercury Flux from Aquatic to Terrestrial Ecosystems**

*M.M. Chumchal, Texas Christian University; R. Drenner, Texas Christian University / Department of Biology*

The diets of terrestrial consumers can be subsidized by energy and nutrients transported from aquatic ecosystems to terrestrial food webs by emergent aquatic insects. However, the cross-system transport of materials by insects can have a "dark side" because emergent aquatic insects also transport toxic contaminants such as methyl mercury (MeHg) to terrestrial ecosystems (hereafter referred to as insect-mediated MeHg flux). Although ecological factors are known to influence insect emergence and the cross-system transport of energy and nutrients by insects, the ecological factors regulating insect-mediated MeHg flux have been little studied. In this presentation we overview our mesocosm and whole ecosystem experiments examining ecological factors regulating the transport of MeHg out of aquatic ecosystems by emergent insects. We also present a conceptual model integrating the influence of MeHg contamination of ecosystems and ecological factors regulating emerging insect-mediated MeHg flux during seasons when insects are emerging. We propose that the potential for insect-mediated MeHg flux increases with Hg contamination of the ecosystem but that the realized insect-mediated MeHg flux is determined by ecological factors known to regulate aquatic insect community ecology.

**TP138 Plasmid profiling of antibiotic-resistant organisms isolated from hospital effluents discharged into Nworie River, Imo State, Nigeria**

*N. Chiegboka, FUTO / Biology; I.O. Emeka-Nwabunia, FUTO / Biotechnology; M.C. Korie, IMO State Polytechnic Umuagwo, Owerri / Science Laboratory Technology*

The emergence of multiple antibiotic resistance in bacteria and the indiscriminate use of antibiotics contribute to the dissemination of resistant pathogen in the environment. Hospital effluents are potential sources of antibiotic resistant bacteria which if released into the rivers leads to the contamination of the water by the resistant strains which are potential threat to human health as they might have direct access to man or transported from sea animals to man through food.Plasmids are major mechanism for the spread of antibiotic resistant gene in bacteria population. Plasmid profiling is one of the methods used to determine and characterize antibiotic resistance traits in bacteria.In this study, a total of eighteen isolates were screened for antibiotic susceptibility out of which eight (8) isolates were resistant to at least five antibiotics. The isolates were tested against ten (10) different antibiotics using the disc diffusion method while the plasmid DNA were extracted using the TENS extraction method and separated by agarose gel electrophoresis of which four out of the resistant strains had plasmid DNA.

**TP139 The incorporation of elements derived from diluted bitumen into the aquatic food web as reveled by stable isotopic analysis**

*J. Mason, Queens University / School of Environmental Studies; D. Orihel, Queens University; D. Layton Matthews, M. Leybourne, Queens University / Geology; B. Hollebone, Environment and Climate Change Canada; M.L. Hanson, University of Manitoba / Environment and Geography; J.M. Blais, University of Ottawa / Biology; V. Palace, IISD-Experimental Lakes Area; J. Luis Rodriguez Gil, University of Ottawa*

Bitumen mined from the Canadian Oil Sands is highly viscous, so it must be diluted with lighter condensates to facilitate its transport through pipelines, yielding diluted bitumen (commonly referred to as dilbit). Dilbit is transported across Canada in large volumes and puts the sensitive freshwater ecosystems that these pipelines traverse at risk. To better understand the fate and effects of diluted bitumen spills in freshwater, we are conducting a mesocosm experiment at the IISD-Experimental Lakes Area in northwestern Ontario, Canada, called the BOREAL (Boreal Lake Oil Release Experiment by Additions to Limnocorrals) study. This study involves simulating an ecosystem-based pipeline spill in 10-m diameter mesocosms installed in the littoral zone of a boreal lake. Different doses of diluted bitumen are added to the mesocosms, simulating a range of environmentally-realistic spill sizes. Traditionally, stable isotope analyses were used to reconstruct food webs, but this technique may also be a powerful means of monitoring petrogenically sourced elements through a food web following an oil spill. We are evaluating the use of carbon, nitrogen, and sulfur stable isotopes as tools as the isotopic signatures of dilbit differ from that of the aquatic food web. Carbon isotopes reflect diet, nitrogen isotopes indicate trophic level, and sulfur isotopes reflect the relative importance of various diet sources. By combining the findings of these three isotopes, the incorporation of dilbit derived elements may be monitored. We collected samples of microbes, phytoplankton, periphyton, zooplankton, fingernail clams, and fish muscle tissue. Samples will be analyzed by stable isotope ratio-mass spectrometry analysis and compared across dose and time. Stable isotopic analysis of carbon was used to track the Deepwater Horizon oil spill in marine systems and to monitor changes in diet and trophic shifts following the spill, but to date, stable isotopes have not been used as a tool to track oil spills in freshwater ecosystems. The importance of our research stems from its novel application in a freshwater environment, the multi-isotopic approach, and the inclusion of multiple trophic levels within a natural lake food web. Our research will demonstrate the utility and power of applying isotope analysis and the possibility of their application at the site of future oil spills as a tracer of the extent to which organisms can uptake oil derived elements.

**TP140 Understanding the Impact of Vegetation on Water Quality and Biotic Diversity in Agricultural Ditches**

*E. Martin, Arkansas State University / Environmental Sciences; J.L. Bouldin, Arkansas State University / Biological Sciences*

Beginning in the late 1800s, ditch systems in northeast Arkansas were created to drain water from wetlands in the Mississippi River Valley to establish the fertile land for agricultural use. Today, they continue to move water away from fields and discharge into larger streams. This conveyance system is part of the larger Mississippi River drainage basin that feeds into the Gulf of Mexico and contributes sediment and nutrients that exacerbate hypoxic conditions. However, agricultural ditches can be important tools for managing water quality because of their ability to filter sediment and sequester nutrients from field runoff. Aquatic vegetation is an important characteristic of these ditches that influences sediment and nutrient values. Ditches also serve as habitats of ecological importance and act as corridors for aquatic and terrestrial movement between patches within the agricultural landscape. This study investigates the impact of vegetation on water quality and wildlife in agricultural ditches. Ten sites divided between two separate HUC-8 watersheds in northeast Arkansas are measured weekly for three years to monitor water chemistry, turbidity, total suspended solids, total and dissolved nutrients, and chlorophyll *a*. Whole Effluent Toxicity tests are performed quarterly to evaluate the vitality of each site. Bed and bank vegetative coverage is qualitatively characterized at each site and plants are identified to the species level when possible. Spring and summer surveys of macroinvertebrates, amphibians, reptiles, and birds are also conducted. Water quality, sediment, and nutrient variables are compared to vegetation coverage at each site using regression analysis. Sites are then compared between upstream and downstream locations using a Kruskal-Wallis test. Species richness is calculated for each taxa at each site and compared to water quality and vegetative variables. The results of this ongoing study help understand the biological importance of agricultural ditches within the local landscape as well as the in-stream processes that have the potential to improve water quality regionally.

## Pathological Endpoints as Predictive Tools for Relative Ecological Risks of Species

**TP141 Effects of Atrazine on Embryogenesis and Larvae Development of African Catfish, *Clarias gariepinus* (Burchell, 1822)**

*P. Opute, University of Benin, Benin City / Department of Animal and Environmental Biology; E.F. Ejikeme, University of the Witwatersrand, Johannesburg / School of Anatomical Sciences / Faculty of Health Sciences; I.P. Oboh, University of Benin, Benin City / Department of Animal and Environmental Biology; P. Nkomozepi, University of Johannesburg / Department of Human Anatomy and Physiology / Faculty of Health Sciences*

Atrazine is an extensively used herbicide amongst the commonly detected herbicides in freshwater. Early developmental stages of *Clarias gariepinus* are particularly sensitive to water pollution. Freshly fertilized eggs of *C. gariepinus* were exposed to 4µg/L, 8µg/L, 12µg/L, and 16µg/L atrazine through embryogenesis in a static renewal bioassay for 72hours. Seven broad stages of embryogenesis: zygote, cleavage, morulation, blastulation, gastrulation, segmentation, and hatching were observed, photographed and documented live with the aid of a light microscope. The first mitotic cleavage in the control group occurred at 40minutes post-fertilization (pf). However, it occurred at 60minutes pf in the 4µg/L and 8µg/L treatments and 70minutes pf in the 12µg/L and 16µg/L treatments. The first larva emerged at 22 hours at a controlled temperature of 27.0 ± 0.5°C. There was a significant difference ($p < 0.05$) in the hatching rate and percentage deformities between control and treatment groups. Mean total length (TL), mean head length and mean body width of control and exposed larva showed a dose-dependent trend. Larvae deformities such as scoliosis, kyphosis, lordosis, detached yolk, and c-shaped body curvature were observed among treatment groups but were more severe with increasing concentration. These results showed that atrazine delayed embryogenesis and hatching with possible physiological and morphological implications.

**TP142 Oocyte pathology and micro-habitat preference of *T. zilli*, *N. diversus* and *C. gariepinus* within a tropical agrarian catchment**

*A.V. Chukwuka, University of Ibadan / Department of Zoology; O. Ogbeide, University of the Free State / Zoology and Entomology*

Ovarian lesions and defects in three tropical fish species (*Tilapia zilli, Neochanna diversus*, *Clarias gariepinus*) inhabiting a pesticide impacted river was described based on a microscopic analysis. Different pathological alterations were detected in gonads of fishes sampled, including necrotic changes, atretic follicles, intersex, loss of follicular structure, vacuolations. Lesion severity differed across species including intersex and the number of follicles undergoing atresia. Significantly higher number of atretic primary follicles were recorded in benthic species compared to pelagic species. Although different pathological alterations were found in gonads of all species examined, in most cases, it was possible to associate their occurrence of histopathological features with parasitism and ecological behaviour or preferences of the species. Findings suggest that the preference for particular microhabitat may determine ecological risks of a species including, its susceptibility to reproductive toxicity. This study demonstrates the relationship between the uneven distribution of environmental contaminants and the likelihood of relative risks between species occurring within the same habitat.

## Advancing Fate and Effects Modeling and Their Integration to Increase the Relevance and Robustness of Risk Assessments

**TP143 Modeling impacts of climate change: From genomes to phenomes to populations**

*N. Galic, Syngenta Crop Protection, LLC / Environmental Safety; C.L. Buck, Northern Arizona University / Biological Sciences; K. Bicago, São Paulo State University; F. Van Breukelen, University of Nevada, Las Vegas; J.P. DeLong, University of Nebraska, Lincoln; H. Hanson, L.B. Martin, University of South Florida; L.M. Romero, Tufts University; J. Utz, University of Nevada, Las Vegas; A. Hindle, Massachusetts General Hospital*

A significant challenge facing biology is understanding how genotypes generate specific phenotypes that influence population-level responses. Addressing this challenge is most urgent today because managing for impacts of climate change requires both understanding and predicting responses to a changing climate within and across levels of biological organization. The processes governing generation of phenotypes are complex and include nonlinear, multivariate and multilevel interactions. Lower level processes can in turn be constrained by population-level properties, which are nonlinear and vary in space and time. Powerful new technologies have impacted virtually all biological disciplines, allowing for unprecedented rates of collection of sophisticated data (e.g., the 'omics revolution). That said, there has been relatively limited progress in our understanding of the mechanistic interrelationships among genes, environment and phenotype and how these interactions emerge at the population level; this limitation constrains the ability to predict responses to a changing climate. To address this challenge, the National Science Foundation has funded a Research Coordination Network (RCN): Predicting vertebrate responses to a changing climate: modeling genomes to phenomes to populations (g2p2pop). The goal of this RCN is to establish a new collaborative network spanning from genomes to populations to facilitate development of novel quantitative approaches to address the urgent challenge of predicting how vertebrate species and populations will respond to climate change-related stressors. It focuses on the interplay between theory and experimentation to develop mechanistic models of acclimation and adaptation to climate change. Collaboration of empirical biologists and mathematical modelers is critical to identifying links and emergent properties across the biological hierarchy, as well as the relative contributions of plasticity and microevolutionary processes to organismal and population persistence in a changing climate. This RCN is populated initially with 28 US and international participants with collective expertise across the spectrum of biological organization and mathematical modeling. All scientists are welcome and actively sought for inclusion in the network.

**TP144 A generalized life-history model for assessing indirect effects of pesticides on fish populations**

*N. Ralston, Sage Green NRG / Earth Systems Science and Policy; A. Schmolke, Waterborne Environmental, Inc. / College of Biological Sciences; B. Kearns, Waterborne Environmental, Inc. / Geospatial Data Technologies; C. Roy, K.E. Kapo, Waterborne Environmental, Inc.; M.E. Kern, Waterborne Environmental, Inc. / Ecotoxicology Risk Assessment; A. Samel, FMC; V. Forbes, University of Minnesota / Ecology, Evolution & Behavior*

Assessing population-level effects of stressors, such as pesticides, across species is challenging because effects are influenced not only by individual-level toxicity but also by species' life history characteristics, ecology, and the duration, magnitude, and frequency of stressor exposure. Additionally, potential indirect population-level effects of stressor exposure (for example, effects resulting from changes in food availability) add further complexity to the assessment. To address these challenges, we developed a generalized population model for small fishes for assessing potential indirect effects of pesticide exposure on population dynamics. We applied the model to 17 species of darter (Percidae: Etheostomatinae) for which life history and diet data were readily available. The selected darter species (including two species listed under the Endangered Species Act) cover a range of life history strategies and diet compositions within the subfamily. We simulated several scenarios of pesticide exposure to assess how potential impacts of a pesticide on various prey species (invertebrates) included in the diets of selected darter species might affect darter population dynamics over extended time periods. We also investigated correlations between life history characteristics and population responses to the exposure scenarios. This analysis provides a framework for predicting food web mediated effects of pesticides on darter species for which little life history information is available. By combining life history variability in fish with estimates of potential indirect effects of pesticides on their prey, our model can provide a valuable tool for incorporating ecological complexity into the assessment process to quantify population-relevant risks to listed and non-target species of small fish.

**TP146 Spatial and temporal variations of national cropping patterns for higher-tier pesticide exposure assessment**

*C.M. Holmes, Waterborne Environmental, Inc.; J. Amos, Waterborne Environmental, Inc. / Geospatial Data Technologies; P. Hendley, Phasera Ltd; R.L. Jones, Bayer CropScience / Environmental Safety; S. Jackson, Valent USA Corp*

Pesticides are used on numerous agricultural crops across the United States to control pests and improve food yield and quality. This presentation focuses on the spatial and temporal aspects of a national scale assessment conducted by the Pyrethroid Working Group (PWG) to characterize the potential for pyrethroids to enter flowing surface waters based on a spatially explicit analysis of crop proximity to surface waters using multi-year data on diverse agricultural production patterns. Standard exposure calculations in the USEPA EFED regulatory risk assessment framework assume that 100% of the area around the water body (the Tier II pond) is cropped and treated, and therefore subject to drift and runoff entry. Over two million catchments within the National Hydrography Dataset (NHDPlus) were characterized using geospatial data to develop national or regional metrics related to potential surface water exposure related to crop proximity for more than 10 crop types. Crop locations were based on five years of data from USDA NASS Cropland Data Layer. Results highlight the variability of cropping density at the catchment scale across different geographies and scales, as well as situations in which density of potentially highly exposing crop (e.g., within 200m of surface water) may not match 'entire catchment' cropping density patterns. Variations in cropping density (as a proxy for potential exposure) across multiple years will be discussed in relation to how this variability may influence exposure estimates. When examining all catchments containing a specific crop, the 90$^{th}$ percentile crop density values (based on the 200m proximity zone) ranged from 1.3% (for vegetables in FL) to 44.4% (for tree nuts in CA). The resulting datasets provide a useful set of metrics across multiple crops which can be applied to pesticide exposure assessments that may need spatially-explicit refinements related to crop-water interactions. Because the crop proximity results are linked to the NHD+ framework, including these specific attributes into other NHD+-based analyses is extremely efficient.

**TP147 A Computational Approach for the Ecological Prioritization of Organic Chemicals in Canada: ERC 2.0**

*M.A. Bonnell, J. Prindiville, M. Jagla, C. Inglis, Environment and Climate Change Canada / Ecological Assessment Division*

In 2016 Environment and Climate Change Canada (ECCC) published the Ecological Risk Classification (ERC), a computational approach used for the re-prioritization of 640 organic chemicals originally prioritized in 2006 as persistent or bioaccumulative and inherently toxic (BT and PT chemicals). The ERC is a multi model risk-based system and was developed to optimize the use of new approach methods (NAMs) in ecotoxicology as well as new developments in fate and exposure science. The ERC is based on the concept of establishing chemical profiles for hazard and exposure. Each profile contains several descriptors that define both the toxicological and exposure spaces used within the profile. The profiles combine data from in chemico, in silico, in vitro and in vivo data to provide several lines of evidence for hazard, exposure and ultimately risk classification for hundreds or thousands of chemicals. The second version of the ERC (ERC2) is under development by ECCC for the prioritization of approximately 12200 organic chemicals on the DSL not prioritized in 2006 as PBT, BT or PT chemicals. New in silico and in vitro tools and data useful for ecological prioritization have become available since 2016 allowing expansion of the hazard rules and descriptors, in particular, from the first version of ERC. Here we present the conceptual model used for ERC2 including the boundaries for data acceptability (e.g., model domain of application, model consensus) and confidence scoring of descriptors used in hazard and exposure classification. ERC2 involves big data and includes information for many hazard and exposure descriptors. It provides ECCC with one approach (substance-by-substance) when considering chemical priorities for post 2020 chemical's management work planning. ERC2 can also be used to aid responses to various regulatory questions or needs outside of substance-by-substance ranking of risk (e.g., identification of potential endocrine active substances, regrettable alternatives, high hazard or exposure concerns, potential research and monitoring priorities).

**TP148 Modelling the fate and distribution of PFASs in the San Francisco Bay**

*F. Sánchez Soberón, Universitat Rovira i Virgili / Chemical Engineering; S. Santini, Rovira i Virgili University; R. Sutton, M.D. Sedlak, San Francisco Estuary Institute; M. Petreas, California Environmental Protection Agency / Department of Toxic Substances Control / Environmental Chemistry Laboratory; M. Schuhmacher, Rovira i Virgili University / Departament d Enginyeria Química; J. Park, California Environmental Protection Agency / Department of Toxic Substances Control / Environmental Chemistry Laboratory; D. Yee, San Francisco Estuary Institute*

Per and polyfluoroalkyl substances (PFASs) are a class of compounds extensively used in food packaging, commercial goods, and aqueous film forming foams used to extinguish fires. Some of these compounds, such as perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS), are highly persistent in the environment and living organisms, and can cause adverse health effects, such as endocrine disruption, immunological suppression, and cancer. Elevated concentrations of PFASs, particularly PFOS, have been observed in San Francisco Bay biota. To properly assess the fate of PFASs in the environment and potential risks to humans and the ecosystem, it is necessary to better understand the long-term trend concentration of PFASs in water and sediments. To address this need, we have developed a long-term mass balance constant rate model for PFASs, using PFOA (whose production was phased-out in the U.S. in 2015) as a model compound. We used sediment and water concentrations reported in 2009 as initial concentration values. We also included as inputs in the model the concentrations measured in wastewater treatment plant effluents and stormwater as external loads, as well as estimated contribution from rivers and atmospheric deposition. Our preliminary results suggest that, if actual external loads remain stable, levels of PFOA would decrease in both water and sediment, reaching values ranging between $10^{-1}$-$10^{-2}$ ng/g in sediment and 4.0 -4.5 ng/L in water by year 2052. The total mass of this pollutant within the estuary would be close to 30 kg, out of which, around 75 % would be present in the water compartment. Validation of these results with actual PFOA sediment concentrations from 2010, 2012, and 2014, showed values within the range of results of the different predictive scenarios.

**TP149 Modelling nitrogen fixation in crude oil polluted oil palm plantation in Owaza, Rivers State, Nigeria; a case study on ecosystem damage**

*A.I. Onwurah, University of Nigeria, Nsukka / Environmental Management; I.N. Onwurah, University of Nigeria / Biochemistry*

Crude oil exploration, mining and urbanization influence the dynamics of the environment and could pose adverse effects on ecosystem integrity. Nitrogen fixation in such environment suggests the presence of diazotrophic bacteria. Hence risk assessments, emergency response decisions, and damage assessments for oil and chemical spills in such ecosystem can rely on or modelled with a relevant biomarker. In situ measurements of chemical concentrations in spill-impacted water or soil may provide insight about chemical transport but may not give the degree of risk or damage to the ecosystem without integration of the biological component. Although a biological receptor component in risk assessment may pose an additional degree of complexity, it is most likely to provide a more realistic assessment in terms of biomarker relevance, time and space. In this work, we propose a nitrogen fixation model for crude oil polluted soil ecosystem based on the case study of the oil spill that took place in Owaza oil palm plantation in Nigeria in 1996. Nitrogen fixing bacterium *Azotobactervinelandii*, a diazotroph is a proven biomarker as it provides an important biological function ($N_2$-fixation) that can be related to an exposure to, or toxic effect of an environmental chemical or chemicals. This biological response can provide qualitative and semi-quantitative information on the quantum of the oil spill, and information on the relationship between $N_2$-fixation and levels of oil pollution in the given oil polluted ecosystem. The biological function F, which corresponds to the entire cellular activity of the diazotroph, is the production of $NH_4^+$ ($N_2$-fixation) by the nitrogenase enzyme complex. The mathematical model governing the entire process ($N_2$-fixation) is based on cybernetics and structured approach to biochemical processes in microbial cells. With this model, an empirical assessment can be made concerning the damage caused to the oil palm plantation ecosystem by the oil spill incident in terms of nitrogen fixation that was compromised, relative to control (site without oil spil incident).

**TP150 Age-dependent Human Elimination Half-lives of DL-PCBs Using the Cross-Sectional Biomonitoring Data in General Population**

*Q. Gao, Peking University; Z. Dong, Beihang University; Y. Ben, J. Hu, Peking University*

Elimination half-life is crucial in the application of pharmacokinetic model to assess human health risk of PCBs. Previous studies used constant half-lives to estimate PCBs elimination in human body, while mounting studies indicated elimination rate, as well as half-lives, may be affected by age. In this study, 306 general populations were recruited and blood samples were collected in 2012. Meanwhile, dietary structure-based food samples were collected and daily intake of dioxin-like PCB were estimated. The first-order model was employed to simulate the human biomonitoring data, while exponential model, linear model and constant model were used to determine the relationships between elimination rate and age. For people aged 20-50, the average half-life of PCB189 is the shortest (from 0.67 years to 1.23 years), followed by PCB126 (2.98 years to 5.43 years), PCB123 (2.96 years to 5.72 years), PCB157 (4.65 years to 6.66 years), PCB105 (4.87 years to 7.46 years), PCB114 (6.07 years to 9.82 years), PCB169 (6.50 years to 7.87 years), PCB118 (6.90 years to 8.51 years). Half-life values of PCB167 and PCB156 were age-independent, and 8.05 years and10.55 years, respectively. The results show half-lives of high halogenated dioxin-like PCBs are longer than that of low halogenated dioxin-like PCBs except for three congeners of them: PCB189, PCB157 and PCB118. Our results for the first time clarified the effects of age on elimination rate of dioxin-like PCBs. Our research provide an important basis for making accurate health risk assessments for dioxin-like PCBs.

## Human Health and Ecological Risk Assessment of Per- and Polyfluoroalkyl Substances

**TP151 Unique Challenges in Site Specific Risk Assessment at a Receptor-Diverse PFAS Site Investigation Area in Jervis Bay, Australia**

*H.A. Lanza, GHD / Environmental Toxicology; L. Gedge, GHD Pty Ltd / Contamination Assessment & Remediation; A. Kohlrusch, GHD Pty Ltd / Contamination and Remediation; D. Morgan, E. Friebel, GHD Pty Ltd; J. Woodworth, GHD / Environment; D. Hager, A. Smit, GHD Pty Ltd*

Environmental risk assessment at PFAS impacted sites continues to evolve and presents unique challenges due to the persistence, ubiquity and uncertain toxic effects associated with this class of compounds. The Australian Department of Defence (DoD) has been at the global forefront of PFAS site investigations and risk assessments, sponsoring robust characterisation at sites around the nation with the aim of informing associated management and remediation options for beneficial project outcomes. Jervis Bay Range Facility (JBRF) and HMAS Creswell (collectively considered within the broader Jervis Bay area) is one of these investigation areas, and is complex in that four habitats (terrestrial, freshwater, estuarine and marine) support both an abundance of ecological diversity in addition to the resident Wreck Bay aboriginal community. This diverse ecology and extensive community use of the land presents a unique challenge from a risk assessment perspective and requires consideration of a myriad of biological trophic levels and exposure pathways beyond what would be required at a less complex location. This project encompassed a comprehensive sampling program for flora and invertebrate and vertebrate fauna from all four biomes to inform both a human health and ecological risk assessment (in development). This case study details some of the unique considerations required for this investigation, including non-standard exposure assumptions and the moving targets inherent in PFAS investigations as a result of evolving knowledge and regulatory guidance. The project will continue to be a valuable addition to the industry's understanding of assessing this difficult class of compounds, as well as providing an extensive characterisation of PFAS in a variety of media to help advance the scientific knowledge base.

**TP152 Comprehensive Analysis of PFAS in Terrestrial, Freshwater, and Marine Food Webs at Jervis Bay, Australia to Inform an Ecological Risk Assessment**

*H.A. Lanza, GHD / Environmental Toxicology; L. Gedge, GHD Pty Ltd / Contamination Assessment & Remediation; A. Kohlrusch, GHD Pty Ltd / Contamination and Remediation; J. Woodworth, GHD / Environment; D. Morgan, T. Steele, D. Hager, GHD Pty Ltd*

The Australian Department of Defence (DoD) is in the process of undertaking a national program to investigate PFAS impacted bases around the nation. Jervis Bay Range Facility (JBRF) and HMAS Creswell (collectively considered within the broader Jervis Bay area) is one of these investigation areas, and is complex in that four habitats (terrestrial, freshwater, estuarine and marine) support both an abundance of ecological diversity in addition to the resident Wreck Bay aboriginal community. The Jervis Bay peninsula, upon which JBRF is set, drains into two distinct catchments, encountering the terrestrial and freshwater ecosystem in Booderee National Park before draining into Jervis Bay to the north and Wreck Bay to the south of the peninsula. The diverse and sensitive ecological receptors in the area required a comprehensive sampling program for flora and invertebrate and vertebrate fauna from all four ecosystems to inform a detailed ecological risk assessment (in development). This case study considers the observed accumulation in biota collected from the region in relation to other risk assessments completed to date, and summarises the potential for risk to this diverse ecosystem. Importantly, the current body of evidence does not suggest adverse effects as a result of PFAS exposure in Australian ecosystems. The project will continue to be a valuable addition to the industry's understanding of assessing this difficult class of compounds, as well as providing an extensive characterisation of PFAS in a variety of media to help advance the scientific knowledge base.

**TP153 Occurrence of perfluorooctanoic acid (PFOA) and Perfluorooctane sulfonate (PFOS) in river system and probabilistic hazard risk assessment**

*B.O. Fagbayigbo, Cape Peninsula University of Technology / Environmental Health and Occupational Studies; B. Opeolu, Cape Peninsula University of Technology / Faculty of Applied Sciences; O.S. Fatoki, O.S. Olatunji, Cape Peninsula University of Technology / Department of Chemistry*

Levels of perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS) in surface water and sediment samples from rivers in South Africa were determined using ultra performance liquid chromatography coupled with quadrupole time of flight (UPLC-QTOF-MS). Concentrations of PFOA in surface water ranged from < LOD to 1929.8 ng/l and concentrations of PFOS ranged from < LOD to 1289.00 ng/l. On the other hand, concentrations of PFOA in sediment samples ranged from < LOD to 214.5 ng/g for PFOA and concentrations of PFOS ranged from < LOD to 246.2 ng/g. Level of PFOA and PFOS obtained from this study were subjected to probabilistic hazard risk assessment to predict the possibility of exceeding suggested threshold limits. Results show that PFOA in water as established by United States Environmental Protection Agencies (USEPA) and Department of Water Council (DWC) Germany threshold limits were exceeded, with distributions of 54 and 56 % respectively for Plankenburg River, and distribution of 50 and 52 % in Diep River. While, percentages exceedent for PFOS in Plankenburg River were 56 and 58 % for USEPA and DWC respectively, and percentage exceedence of 50 and 55 % for Diep River. Continuous release of PFOA and PFOS in the river system could leads to elevated levels; hence trigger environmental and hazard risk to the ecosystems.

**TP154 PFAS Elimination in Eggs of Hens Exposed via Drinking Water**

*M. Archer, AECOM Australia Pty Ltd / Geosciences and Remediation Services; T. Wilson, P. Scott, Scolexia Animal & Avian Health Pty Ltd*

Background/Objectives Hens that are exposed to per- and poly-fluoroalkyl substances (PFAS) via drinking water, food and soil eliminate/excrete PFAS in eggs. The consumption of eggs from backyard hens has the potential to represent a significant dietary exposure pathway for people living in areas where soil and water have been contaminated by PFAS. However, few studies have been published to quantify the relationship between PFAS concentrations in eggs and environmental media, representing a source of uncertainty for human health risk assessment (HHRA) of PFAS in the environment. The objective of this study was to characterise PFAS concentrations in eggs at a range of PFAS concentrations in the hen's drinking water, and evaluate whether PFAS concentrations in chicken eggs could be estimated based on the hen's PFAS intake from drinking water. Methodology The study involved 119, 30-week-old Hy-Line Brown hens that had started egg-laying prior to introduction to the trial. The hens involved in the study were managed with due regard for their welfare as required under an animal ethics approval. The PFAS examined were perfluorooctane sulfonate (PFOS), perfluorohexane sulfonate (PFHxS), perfluorooctanoic acid (PFOA) and perfluorohexanoic acid (PFHxA). There were four treatment groups for the study, with each group provided drinking water with the same concentration of each of the four PFAS (0.3 mg/L, 3 mg/L, 30 mg/L and 300 mg/L). There was also one control group, where the chickens were provided drinking water with no detectable PFAS. After a 14 day pre-treatment phase to acclimatise birds to the study conditions, the hens were exposed to PFAS in their drinking water over a 61 day treatment phase aiming to evaluate long-term average egg PFAS concentrations likely to be encountered at each treatment concentration. Egg samples and drinking water samples were collected during each phase of the study. Results Key findings were as follows: No changes in health or productivity (e.g. hen's body weight, egg weight, egg laying rate or water consumption rate) were observed in hens from all treatment groups during the study. The amount of PFAS in the edible part of the egg was found to be proportional to the amount of PFAS consumed by hens in their drinking water. PFAS was primarily detected in the yolk of the egg, with negligible amounts in the egg white. PFOS elimination/excretion in eggs was greatest for PFOS, followed by PFHxS, and notably lower for PFOA and PFHxA.

**TP155 Data to support the development of wildlife toxicity reference values for per- and polyfluoroalkyl substances**

*A. Jackovitz, US Army Public Health Center / Toxicology; M. Quinn, Army Public Health Center / Health Effects*

Per- and polyfluoroalkyl substances (PFAS) are compounds manufactured for use in paints, cleaning agents, fire suppressants, non-stick cookware and food containers, and water-impermeable products in general. Concerns about PFAS stem from their ubiquitous presence in the environment, widespread reports of general toxicity, and the resistance of these compounds to degradation. In a range-finding experiment, six PFAS (perfluorooctanesulfonate (PFOS), perfluorooctanoate (PFOA), perfluorohexanesulfonate (PFHxS), perfluorobutanesulfonate (PFBS), 6:2 fluorotelomer sulfonate (6:2 FTS), and perfluorononoate (PFNA) were administered to the white-footed mouse (*Peromyscus leucopus*) for 28-consective days. The goal of the study was to ensure bioaccumulation and sufficient body burden of the chemicals for follow-up reproductive/developmental toxicity studies, which will be used to derive wildlife Toxicity Reference Values (TRVs). In addition to determining steady state dynamics and possible target organs, mortality data were used to develop interim TRVs. Wildlife TRVs and increased understanding of PFAS in general, will assist in the development of appropriate site-specific risk assessment and decisions related to mitigation of exposures and/or future cleanup.

**TP156 Per- and polyfluoroalkyl substance (PFAS) prioritization and risk factors for terrestrial ecological receptors**

*A. East, Towson University / Environmental Sciences; R.H. Anderson, US Air Force / ORD / NCEA; C.J. Salice, Towson University / Environmental Science & Studies Biology*

Per- and polyfluoroalkyl substances (PFASs) remain a complex environmental contamination and management problem. Challenges in evaluating risk of PFASs as both individual compounds and mixtures to ecological receptors lie in the shortage of toxicity data and the need to prioritize relevant PFASs. Environmental sampling data show that most PFASs exist in the environment as complex mixtures. However, these mixtures and, importantly, their parent formulations are not consistent in space nor time so determining the most relevant PFAS(s) for ecotoxicity testing and risk assessment remains critical. We developed a method to help prioritize compounds for testing and risk assessment from environmental sampling datasets. The method explicitly considers environmental concentrations, frequency of detection and sampling, and several metrics related to uncertainty and mixture characteristics. Surface water and soil concentration datasets, respectively, were used to initially develop and then apply the method. We found that PFOS and PFHxS are likely the majority PFASs of concern. Others such as PFOA, PFHxA, and the fluorotelomers (6:2, 8:2 FTS and FOSA) are of concern, but with lower confidence. In order to more explicitly link this exposure profile to an ecologically relevant endpoint, we used PFOS specific toxicity reference values (TRVs) for avian and reptile receptors as threshold effect levels to explore how environmental concentrations may translate to potential risk. We used BSAF values for soil dwelling invertebrates paired with incidental soil ingestion estimates for birds and reptiles to estimate sum PFAS uptake through diet and soil exposure. As the input data for this estimate is a distribution of soil concentrations from PFAS contaminated sites, the resulting distribution of daily intake values can then be compared against TRVs. Results suggest that 8 to 38% of sites would be in exceedance of TRVs, depending on species- and environment-specific factors. Importantly, the likelihood of this intake varies across individual compounds due to varying BSAF values and across locations due to the influence of site-dependent characteristics (e.g. the specific PFAS mixture). In summary, we have demonstrated the application of a method useful in screening a large number of sites and samples to identify priority PFASs, risk drivers, and to help define key uncertainties in risk estimation.

**TP157 PFAAs and EcoRisk: Development of a Hazard Ranking System by Evaluating Functional Groups vs. Chain Lengths as Primary Risk Drivers**

*J.K. Wilhelm, A. Luz, A. Luz, P.E. Goodrum, Integral Consulting Inc.*

Per- and polyfluoroalkyl substances (PFAS) are a vast group of chemicals with varying properties and rapidly developing science. While ecological risk assessment frameworks exist to address emerging contaminants such as PFAS, there are few working examples, and many questions remain regarding appropriate methods to apply when PFAS mixtures are detected at a site. This presentation focuses on perfluoroalkyl acids (PFAAs), which have been detected ubiquitously in the environment, and are expected to persist in biotic and abiotic media and potentially to bioaccumulate. Historically, PFAAs have been classified into groups based on their carbon chain length and associated carboxylate or sulfonate functional group. However, there is growing evidence that variability in relative potencies and bioaccumulation potential warrants a more refined classification system. Toxicological studies useful for ecological risk assessment have focused predominantly on two of the most commonly detected long-chain PFAAs, perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS). It is now understood that there are important differences in relative potency among PFAAs with the same carbon chain length, in part due to differences in functional groups, but also due to variability in species sensitivities. This presentation will highlight key factors that may explain differences between PFAAs in kinetics and target tissue concentrations. We propose a framework for incorporating such information in a site-specific hazard ranking system for both long- and short-chain PFAAs as they relate to aquatic and mammalian ecological receptors.

**TP158 Applying a "One Health" Approach to the Assessment of PFAS**

*T. Lopez, Tetra Tech, Inc.; M.S. Bowersox, Tetra Tech, Inc. / Laboratory Department; J.M. Diamond, A.M. Bernhardt, R. Kotun S. Richards, Coffey; D.H. Homer, Tetra Tech, Inc.*

The One Health concept recognizes the interconnected health of the environment, animals and humans and that a transdisciplinary approach can achieve optimal health outcomes by recognizing these interactions. Due to their ubiquitous presence from widespread usage in consumer products, commercial operations, and firefighting, and their environmental persistence, per- and polyfluoroalkylated substances (PFAS) are globally distributed in the environment and detectable levels of PFAS are present in virtually all humans, as well as, terrestrial and aquatic animals. The One Health concept is used to evaluate PFAS in the environment through a review of toxicity information, fate and transport information, sampling data, and regulatory efforts. Based on environmental media and biota concentrations observed in our work and others at several sites around the globe, we illustrate likely exposure scenarios for biota and humans, and highlight some of the current challenges in assessing risks of this unique class of chemicals. An extensive toxicity database has been compiled for PFAS based on over 250 publications, which is being used to help evaluate potential risks to terrestrial and aquatic systems. Site-specific bioaccumulation rates developed using field data demonstrate that for some types of fauna, bioaccumulation of certain PFAS can be significant. Information from our research and that of others indicates that potential exposure pathways of PFAS in soils, sediments, and water to animals and plants are complete, and PFAS is transported through the food chain, presenting an additional exposure pathway to humans as well. Fish tissue PFAS data, for example, indicate potential linkages between ecological and human health suggesting that consumption of fish may be a major source of exposure to these chemicals. When combined with potential intakes through drinking water as well as consumer exposures through household items, the possibility exists for much higher intakes and much longer-term exposure than estimated through environmental media alone. Using a One Health approach will help promote integrated assessments of PFAS as well as promoting discussion of the potential effects at the population level from current and continued exposures to PFAS through environmental media.

**TP159 An Evaluation of Perfluoroalkyl Substances-based Fish Consumption Advisories in North America**

*R.R. Holem, GEI Consultants; J. Newsted, OBG*

Perfluoroalkyl substances (PFAS) are synthetic compounds that are persistent and resistant to degradation in the environment and have received considerable attention with respect to their occurrence and fate in the aquatic environment and biota. Consumption of fish is a known source of human exposure to PFAS, particularly PFOS. As such, PFOS-based fish consumption advisories (FCAs) have been issued in several US states and Canada. Fish tissue PFOS concentrations and the methodology and assumptions (e.g., fish consumption rate) used to develop PFOS-based FCAs will be examined. Case studies of locations with significant PFAS fish tissue data will be presented. Factors such as the water body type (lentic vs. lotic) in which PFAS-based advisories are present, PFAS concentrations across fish species, and species-specific bioaccumulation will be discussed. The extent of PFOS-based FCAs will be compared to that of legacy compounds such as Hg and PCB to assess if PFOS-based FCAs are greater or less restrictive in areas where these compounds have been quantified.

**TP160 ITRC Project Team on Per- and Polyfluoroalkyl Substances (PFAS)**

*Y. Lowney, Alloy, LLC / Health Sciences; L.H. Wilson, Sage Risk Solutions LLC; R. Mueller, New Jersey Department of Environmental Protection / Division of Science, Research, & Environmental Health; V. Yingling, Minnesota Department of Health / Environmental Health; P. Reyes, ITRC*

PFAS are a large and complex class of anthropogenic compounds whose prevalence in the environment have become an emerging, worldwide priority in environmental and human health. Some PFAS are environmentally persistent and bioaccumulative and may pose human health risks. Recent high-profile cases involving human exposure in the United States have further focused both public and regulatory scrutiny on PFAS. The scientific community's understanding of PFAS sources, site characterization, environmental fate and transport, analytical methods, and remediation is growing rapidly. However, there is no central clearinghouse available that presents this information in a manner readily accessible to those other than subject-matter experts. As a result, there is a gap in the broad technical understanding necessary for informed and expedited decisions by regulators and policy makers. In response to this information need, ITRC formed a technical team to produce concise technical resources that will help regulators and other stakeholders improve their understanding of the current science regarding PFAS. This poster will provide an overview of the ITRC Team progress, goals, and specific efforts that have been conducted or are underway under the ITRC PFAS team. These include: Fact Sheets: ITRC has developed a series of fact sheets, each synthesizing key information for one of the following core subjects: Naming Conventions and Physical and Chemical Properties Regulations, Guidance, and Advisories History and Use Environmental Fate and Transport Site Characterization Considerations, Sampling Precautions, and Laboratory Analytical Methods Remediation Technologies and Methods Aqueous Film forming foams (AFFF) to be published in August 2018 Technical and Regulatory Guidance Document: The project team is in the process of developing a technical and regulatory guidance document and an internet-based training course, that address the technical focus areas bulleted above. The guidance document will be a web-based resource for environmental project managers. The document and training will provide links to pertinent scientific literature, stakeholder points of view, technical challenges and uncertainties, and the necessary breadth and depth not given by the fact sheets.

**TP161 Phytoextraction of PFAS: Compounding Exposure Risks?**

*U.K. Vedagiri, AECOM / Design and Consulting; B. Harding, AECOM; H. Loso, AECOM / Remediation*

Phytoextraction of PFAS by way of passive and active plant pumping mechanisms has been documented in both laboratory and field scale studies. This presentation explores plant uptake of PFAS, plausible phytoremediation mechanisms, and considers the ecological merits and liabilities of transferring PFAS into biotic media. Plant uptake of both short-chain and long-chain PFAS compounds is well-documented in both herbaceous and woody vegetation. Phytoextraction is currently under consideration as one element of multi-pronged remediation strategies for PFAS in soil and groundwater where cultivation and harvesting/removal of PFAS-accumulating plant species may be a useful risk management tool. However, the plant uptake behavior may also contribute to ecological risks related to PFAS when herbivorous receptors feed upon vegetation. Field studies of PFAS uptake at contaminated studies reveal differential patterns of uptake and accumulation depending on chemical chain length, functional group, soil and groundwater geochemistry, plant species and plant parts. This study utilizes available project-specific field data and literature to identify the ecological benefits and concerns related to PFAS under phytoremediation and risk management scenarios. Data from soil and groundwater phytoremediation studies using historically-documented plant species and data from various sites are evaluated and presented from human and ecological risk perspectives. These risk-based models can serve as decision trees which support practitioners in evaluating the net benefits of applied phytoextraction at PFAS sites and plant-uptake studies.

**TP162 NMR Metabolomics Study of Arabidopsis Exposure to PFOA and PFOS**

*L. O'Hara, University of Guelph / School of Environmental Sciences; J. Konzuk, Geosyntec Consultants; J. Longstaffe, University of Guelph / School of Environmental Sciences*

Perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS) are environmental contaminants originating from their use in industrial surfactants, textile finishes and flame retardants. Their widespread use has resulted in these compounds becoming ubiquitous environmental contaminants. The persistence of PFOA and PFOS poses an ecological and health risk due to movement up the food web through bioaccumulation. Non-targeted metabolomics provides an avenue to determine the subtle responses by plants when exposed to these compounds at environmental levels. This poster presents new work exploring the application of non-targeted metabolomics using nuclear magnetic resonance (NMR) as an approach to understanding the affect of PFOA and PFOS contamination on plants. *Arabidopsis thaliana* has been chosen as the model organism, as previous studies have shown signs of oxidative stress at high concentrations of PFOA. Non-targeted metabolomics will provide insight into changes expressed in the metabolism of the plants when exposed to environmentally relevant contamination levels. By employing principal component analysis (PCA), metabolic profiling can be used to determine biomarker metabolites for *A. thaliana* response to PFOA and PFOS contamination. This method could potentially be used on a wide range of species to determine whether they show signs of exposure to PFOA or PFOS contamination at levels that may otherwise be difficult to monitor.

**TP163 Perfluorohexanesulfonate (PFHxS) induced apoptosis of neuronal cells via the altered signaling pathways**

*S. Park, Daegu Catholic University / Pharmacology / Toxicology; J. Yang, Catholic University of Daegu / Pharmacology*

Perfluorohexanesulfonate (PFHxS), one of the major perfluoroalkyl compounds (PFCs), has widely been used in a variety of industrial and consumer applications and detected in humans as well as wildlife. Recently, it is reported that PFHxS levels in the cord blood are associated with birth outcomes in the general population. This raised a great concern over its developmental health effects, including neurotoxic effects. While apoptosis of neuronal cells is a key element in neurotoxicity, its underlying mechanism of PFCs-induced apoptosis remains unclear. It has been reported that AMP-activated protein kinase (AMPK) acts as a key signal molecule in neuronal excitotoxicity as well as providing a neuroprotective function. In the present study, we examined the involvement of AMPK in PFHxS-induced neuronal apoptosis using neuronal differentiated PC12 cells, in an attempt to dissect the signaling mechanism. PFHxS induced significant increases in intracellular [$Ca^{2+}$] via the NMDA receptor and the L-type voltage-gated calcium channel (L-VGCC). The inhibition of $Ca^{2+}$ loading by the NMDA receptor antagonist, MK801 and the L-VGCC blockers, nifedipine and diltiazem significantly reduced PFHxS-induced apoptosis. PFHxS induced sustained activation of AMPK and the inhibition of AMPK activation by compound C and AMPK siRNA significantly reduced PFHxS-induced caspase-3 activity. These results indicate the pro-apoptotic role of AMPK. The activation of AMPK was attenuated by MK801, nifedipine and diltiazem. However, the activation of AMPK was not affected by the ERK inhibitor, PD98059. Likewise, ERK activation was not affected by compound C but was substantially reduced by MK801, nifedipine or diltiazem. This suggests that the activation of AMPK and ERK is regulated by intracellular $Ca^{2+}$ loading in distinct pathways. Taken together, PFHxS-induced neuronal apoptosis is mediated by AMPK and ERK pathways. Our findings provide evidence for the underlying mechanisms responsible for PFHxS-induced neuronal damage, which may contribute to identifying target molecules critical for assessing PFC-related neurotoxicity.

**TP164 Effects of PFAS on Sensitive Life Stages of the Fathead Minnow**

*J.G. Suski, EA Engineering, Science and Technology, Inc., PBC / Water and Natural Resources; C.J. Salice, Towson University / Environmental Science & Studies Biology; M.K. Chanov, EA Engineering, Science, and Technology, Inc., PBC / Ecotoxicology; J. Redifer, M. Jersa, E. Brooks, EA Engineering, Science, Technology, Inc., PBC*

There is widespread and growing concern regarding the environmental effects of Per- and polyfluoroalkyl substances (PFASs). Among the most commonly detected and studied PFAS are perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA). Both of these PFASs have been measured in a wide variety of wildlife tissues, drinking water sources and surface and ground waters. To date, the consensus is that PFOS is likely the most toxic PFAS and generally dominates environmental samples. Importantly, these two PFAS infrequently occur by themselves; there are often a multitude of "other" PFASs that co-occur with PFOS and PFOA although for these PFASs, there are considerably less data. Indeed, even for PFOS and PFOA more toxicity data over critical life stages would be useful in fine tuning toxicity and threshold estimates. Hence, an important research objective moving forward in environmental assessment and management of PFASs is to better define the ecotoxicity of relevant PFASs and PFAS mixtures. We have conducted the first of eight toxicity studies that encompass sensitive life stages critical to reproduction and development on a representative freshwater fish, the fathead minnow (*Pimephales promelas*). These are 42-day studies where exposures occur over spawning and then continue for 21-days of the F1 generation. Preliminary results show that PFOS, a predominant PFAS, significantly decreases survival of the spawning adults at 500 ug PFOS/L; moreover, there is a very clear threshold for developmental effects between 250 and 500 ug PFOS/L where survival significantly decreases from 92% to 10%, respectively. These results in combination with peer-reviewed literature show that high but, environmentally relevant concentrations of PFOS can elicit toxic effects over longer-term exposures highlighting the need to evaluate this class of chemicals under chronic exposure durations.

**TP165 The Effects of Dermal Exposure to Poly- and Perfluoroalkyl Substances on Post-Metamorphic Amphibians**

*S. Abercrombie, M. Iacchetta, Purdue University / Forestry and Natural Resources; C. de Perre, Purdue University / Department of Agronomy; M.S. Sepulveda, Purdue University / Department of Forestry and Natural Resources; L.S. Lee, Purdue University / Department of Agronomy; J.T. Hoverman, Purdue University / Department of Forestry and Natural Resources*

Poly- and perfluoroalkyl substances (PFASs) are distributed throughout ecosystems globally and have been targeted for regulation due to their persistence in the environment, widespread accumulation in both humans and wildlife, and potential for a variety of adverse effects. While PFAS toxicity has been examined in a variety of taxa (e.g., birds, mammals, fish), research on amphibians is limited. We examined the effects of PFAS exposure via contaminated substrate on the survival and growth of juvenile American Toads (*Anaxyrus americanus*), Eastern Tiger Salamanders (*Ambystoma tigrinum*)and Northern Leopard Frogs (*Lithobates pipiens*). Treatments included perfluorooctanoic acid (PFOA), perfluoroocatane sulfonate (PFOS), perfluorohexane sulfonate (PFHxS), and 6:2 fluorotelomer sulfonate (6:2 FTS) at concentrations of 10, 100, and 1000 parts per billion, and a control treatment. Individuals were uniquely identified to assess percent changes in mass and snout-vent length (SVL) over the 30-d experiment. While there was no influence of PFASs on survival or mass of the species, we found significant effects on SVL. Salamanders exposed to PFASs generally exhibited 5 to 10% greater growth in SVL compared to the control, while frogs and toads displayed the opposite pattern. Effects on SVL growth were strongest with exposure to 6:2 FTS and weakest with PFOA. There was limited evidence for a dose-response relationship for the PFASs. We also applied a residual condition index (RCI) to evaluate relative body condition, with controls as our reference RCI. Salamanders showed decreased RCI for all treatments with the exception of PFOS, frogs decreased regardless of treatment, and toads were highly variable. While additional research is needed to determine the mechanisms underlying the contrasting effects of PFASs on salamanders and anurans, our work demonstrates that PFASs can have sublethal effects on amphibians.

**TP166 Adverse Outcome Pathway-based transcriptional point of departure assessment of the effects of perflorooctanesulfonic acid on zebrafish embryos**

*E.J. Perkins, M.S. Wilbanks, N. Vinas, L. Burgoon, US Army Engineer Research and Development Center / Environmental Laboratory*

Perfluoroalkyl substances (PFAS) such as perflorooctanesulfonic acid (PFOA) have been widely used in industrial and consumer products which has led to wide spread contamination of the environment. Chemical concentration thresholds for adverse effects caused by PFOS are needed for protecting both humans and aquatic species. We examined the effects of PFOA on developing zebrafish embryos to identify potential adverse outcome pathways and chemical thresholds by which PFOA can cause developmental toxicity. We exposed zebrafish embryos from 6 hours post fertilization to 96 hours post fertilization to four different concentrations of PFOS. We then used transcriptional and morphological effects to identify potential adverse outcome pathways (AOP) and effect thresholds for PFOS. Morphological effects observed at high doses included swim bladder malformation, cranial malformations, spinal curvature, and embryo orientation. Functional analysis of gene expression indicated that PFOS caused oxidative stress in embryos with antioxidant genes TXN, TXNRD1 and GSS monotonically up regulated, leading to cell cycle arrest with downregulation of genes involved in DNA synthesis, DNA damage repair, telomere extension and cell cycling. Additionally, there was strong down regulation of genes involved in extracellular matrix production including collagen production and lysyl oxidase function indicating a reduction in extracellular matrix. Over all, at high doses, affected gene functions point to a senescence response. Using genes with monotonic dose-responsive expression along with observed apical effects, we developed an AOP network where PFOS causes oxidative stress, leading to autophagy and degradation of the extracellular matrix, altering embryo notochord development and ultimately leading to malformations and mortality. We then calculated an effect threshold level based on a transcriptional point of departure analysis using gene expression in the AOP network. This approach appears promising in identifying plausible AOPs underlying the effects of PFASs and developing AOP based concentration thresholds below which effects are unlikely to be observed. These thresholds can be useful in risk assessment applications by linking mechanisms of toxicity to adverse effects through AOPs.

## Non-Targeted Analysis: Comparing ENTACT Results and Assessing Informatics Approaches

**TP167 Developing non-targeted analysis techniques for chemical prioritization in environmental water samples**

*A. Batt, USEPA / SED / National Exposure Reseach Laboratory; M.S. Kostich, USEPA / ORD / NERL / EMMD*

The analysis of chemical contaminants and their introduction and transport through the environment has been a major focus of environmental work for years, due to their potential to cause undesirable ecological and human health effects. In order to achieve detection levels needed for environmental protection, analytical methods are usually limited to maximum of around 100 compounds. With many tens of thousands of industrial chemicals in use today, prioritizing which analytes or mixtures of analytes should be targeted for analysis has become increasingly difficult. We are developing non-targeted chemical screening tools to look for a much broader range of possible chemical contaminants present in environmental water samples using liquid chromatography and time of flight mass spectrometry (Waters Xevo LC-QToF). Different instrument conditions are being tested, including a variety of LC columns with different sizes and stationary phases (C18, HILIC), different mobile phases and modifiers. Ideal method conditions and criteria needed for data workflow development, including blank subtraction, retention time monitoring, replicate injections, peak alignment, and sequence set up (with possible sample randomization) are also being investigated. Special attention is also being paid to developing laboratory quality performance measures, as this is currently not a standardized aspect of non-targeted analysis. This includes developing protocols for using extraction performance standards, daily instrument performance standards to monitor retention times, sensitivity, and mass calibrations, and optimizing the number of replicate sample injections for different applications. Future work will apply these methods to prioritize which chemicals are responsible for biological activity in complex environmental mixtures, such as municipal wastewater and surface water.

**TP168 Improving non-target analysis by HPLC-ESI/HRMS in the context of the EPA collaborative trial project (ENTACT)**

*B. Ng, Florida International University / Chemistry and Biochemistry; N. Quinete, Florida International University / Analytical Chemistry; P.R. Gardinali, Florida International University / Chemistry & Biochemistry and SERC*

Advancements in analytical chemistry, especially mass spectrometry, have redefined the field of contaminant detection. Majority of approaches for screening of environmental contaminants target individual chemical compounds or classes of chemical compounds using highly specific analytical methods. Despite their ability for low level detection and quantification, novel contaminants or transformation products which may still pose a risk to humans and wildlife are often overlooked by these methods. Non-targeted analysis requires no prior knowledge of compounds and has become very popular in the last couple years for the determination of new and emerging contaminants, or transformation products. The ENTACT sample set was created using about 1200 standard chemical substances from the EPA's ToxCast library to produce 10 liquid mixtures containing 100-400 compounds each. In addition, three types of samples – house dust, human serum and silicon bands – were each spiked with "unknown" standard mixtures to assess different matrix effects. The detection of "unknown" chemicals from the ENTACT samples was carried out by acquiring spectral information using a Q-Exactive Orbitrap mass spectrometer operated at 140,000 resolution power, two ionization modes, and two polarities both under MS and $MS^2$. Subsequent data processing and identification of unknown compounds was performed using the Compound Discover 2.1 software. The blinded results of this study showed that our method identified 2310 features in the standard mixture samples. In the different matrix tested, the highest number of compounds were identified in the silicon band samples, which showed a total of 314 features in the samples (n=2). The human serum samples were found to contain the least amount of compounds; total of 58 features. The performance of our non-target method will be assessed by comparing the results after unblinding.

**TP169 Application of on-line SPE coupled with LC/QToF mass spectrometry to analysis of target and non-target contaminants in water**

*L.K. Kanagy, E.T. Furlong, W.T. Foreman, USGS / National Water Quality Laboratory; D.W. Kolpin, USGS / Central Midwest Water Science Center; P.M. Bradley, USGS / South Atlantic Water Science Center*

High-resolution mass spectrometry (HRMS) increasingly has been used to explore in environmental matrices the presence of previously unidentified compounds beyond those contaminants that are routinely monitored using targeted chemical analytical methods. Identified non-target chemicals might constitute exposure to under-investigated "emerging contaminants" and warrant their inclusion as target analytes in future monitoring programs and effects studies. The USGS National Water Quality Laboratory is using liquid chromatography with quadrupole time-of-flight mass spectrometry (LC/QToF) both for non-target analysis and to confirm the presence of target compounds determined by target-analyte methods (e.g., by LC/tandem mass spectrometry, LC/MSMS). One potential limitation of most LC/QToF systems is that detection limits (DLs) typically are one order of magnitude or more higher than those obtained by targeted LC/MSMS methods (DL ranges of 1-100 ng/L are common for analytes such as pesticides and pharmaceuticals by MSMS). This occurs in part because mass spectrometer dwell times in targeted LC/MSMS methods are sequentially focused on the compounds of interest, while QToF analyzers collect all ion signals concurrently, limiting sensitivity and dynamic range, especially in complex sample matrices. This limits the applicability of the LC/QToF for both targeted and non-target analyses, especially for direct injection analysis of matrices like groundwater and drinking and surface waters with low or sub ng/L contaminant concentrations. To lower DLs, we have applied on-line solid-phase extraction (OLSPE) to pre-concentrate analytes from the sample matrix or sample extract prior to back elution and direct introduction onto the analytical column of the LC/QToF operated in positive or negative electrospray ionization modes. Analyte load and elution conditions were tested using C8 or Oasis® HLB SPE columns (Waters Corp.) and variable pH (3, 7, 10) to identify several optimum OLSPE conditions using a subset of target analytes (pesticides, pharmaceuticals, industrial chemicals) that might be representative of the chemical functionalities of many possible non-target contaminants. The OLSPE LC/QToF procedures were applied to drinking and surface water samples collected for studies conducted by the USGS Toxic Substances Hydrology Program and to test samples from EPA's Non-Targeted Analysis Collaborative Trial (ENTACT). Advantages and limitations of OLSPE are presented.

**TP170 Comparison of workflow techniques for high-resolution mass spectrometry data reduction and prioritization of known, suspected, and unknown contaminants**

*E.T. Furlong, L.K. Kanagy, C.J. Kanagy, W.T. Foreman, USGS / National Water Quality Laboratory*

The rapid expansion and application of high resolution-mass spectrometry (HRMS) analysis techniques to environmental samples has resulted in many different approaches to better characterize complex mixtures of organic contaminants present in environmental samples. Typically, analysis of a single sample can result in thousands of potential contaminant candidates having unique mass spectral and retention time characteristics. Critical components for any HRMS work flow include reducing the inherent complexity of the acquired data by rapidly screening and marking contaminants previously known or suspected to occur (from targeted analyses of the same samples or from similar studies) so that greater effort can focus upon the more complex task of unambiguously identifying unknown contaminants for further assessment and quantitation. There are multiple iterative approaches available to complete these components, but comparison of performance between different approaches has been less frequently evaluated and assessed. We present results from the application of several different approaches to identify known and expected organic contaminants from a common set of environmental and quality control samples. Environmental results for stream samples were obtained from polar organic compound integrating sampler (POCIS) samples, which provide a concentrated extract of great chemical complexity. All POCIS were deployed concurrently in a surface stream reach in the Northeast United States, and, after retrieval, processed identically. POCIS extracts also were analyzed using a targeted HPLC/MS/MS method that determines 109 pharmaceuticals at low ng/L concentrations, providing data for a specific set of compounds found in these same samples. We compared a standard metabolomics software suite (MarkerLynx from Waters Corporation), an open-source data reduction tool (EnviMass, supported by Loos Computing), and the multivariate analysis capabilities of the UNIFI software data processing suite (Waters Corporation) combined with marker screening tools developed in-house using Excel (Microsoft). Preliminary results indicate considerable overlap between candidate marker sets produced by the different software tools, with multiple approaches reinforcing identification of markers associated with specific sample types, and that use of multiple tools provides complementary information for identifying and confirming known, suspected. and unknown contaminants.

## Environmental Risk Assessment

### TP171 A Proposed Method of A Priori Selection of Brood Area to be Monitored in a Brood Termination Study

*A. Warmkessel, S. Ma, G. Kunkel, Smithers Viscient / Carolina Research Center; M. Tomka, Smithers Viscient*

*Apis mellifera* has been identified by the EPA as "an appropriate surrogate for evaluating pesticide risks to bees and insect pollinators in general." As per EPA and OECD guidelines, brood termination is a measure of colony health that is implemented particularly when observing the effects of an insect growth regulator. The guidelines are vague on how brood area that will be monitored throughout the study should be selected. In addition, ways of following brood area over time have grown from using physical markers on the frames to using digital photography of entire frames. The lack of input from the guidelines as well as the change in how data is collected should prompt us to consider "rules" in how brood is selected prior to data collection. These rules take into account the inconsistency between colonies as well as theoretical location of the brood nest within the colony. Putting these selection rules in place would eliminate the need to select brood at the time of, or after, data collection in a subjective manner. This method will be evaluated in the summer of 2018.

### TP172 Acute chronic ratios in algal toxicity

*J. Brill, The Procter & Gamble Co. / Environmental Stewardship and Sustainability; S.E. Belanger, The Procter & Gamble Company / Central Product Safety Dept*

Algal toxicity studies are required by regulatory agencies for a variety of purposes including classification and labeling and for chemical risk assessment. As algae are often the most sensitive taxonomic group (approximately forty percent of the time) and often drive risk assessments. Understanding acute:chronic ratios for algae can be informative for some assessments. Applying acute:chronic ratios is an approach commonly used when one or the other statistical endpoint is unavailable. Complexities to develop acute:chronic ratios for algae exist including a lack of universally agreed upon algal inhibition endpoints, the evolution of experimental designs over time and by different standardization authorities, and changes in statistical emphases (use of regression-based versus hypothesis test-based effect conclusions) which means there is considerable variance among current ACRs. In most regulatory frameworks, the accepted acute:chronic ratio for algae, fish and invertebrates remains 10 regardless of species, chemical type or mode of action. However, information indicates that the acute to chronic ratio for algae is lower than that for fish and invertebrates thus making algae chronic endpoint extrapolation significantly more conservative than necessary. To date, experimental data for developing a globally accepted algal acute:chronic ratio has been limited largely due to data availability. Using the newly developed ecological Thresholds of Toxicological Concern database and a well-structured internal algal database in our possession, we compiled acute and chronic toxicity data on X algae species and Y chemicals. Information was probed for growth rate, yield, and final cell density endpoints focusing primarily on 72 and 96 h duration studies. Comparisons of comparable acute and chronic data (e.g., growth rate) as well as mixed comparisons (e.g., growth rate and final cell density) were used to judge available acute and chronic relationships. Linear regressions of various model permutations were used to establish proposed acute:chronic ratios for various data combinations. Acute:chronic ratios were consistently around 4 regardless of dataset used or combination of endpoints. We propose an acute chronic ratio of 4 for algal toxicity and outline the conditions under which the ACR can be applied as well as indicating areas for further research and improvement.

### TP173 Addressing Issues in Assessing Environmental Fate & Transport for Challenging Chemical Classes

*E. Wong, USEPA / OCSPP / OPPT / RAD; N. Orentas, USEPA; L. Libelo, USEPA / OLEM / OSRTI / SPB*

Determining the fate and transport of chemicals in the environment is central to evaluations of ecological and human health risk under the Toxic Substances Control Act and other EPA authorities. USEPA, Office of Pollution Prevention and Toxics (OPPT)'s fate assessors in the Risk Assessment Division (RAD) have developed approaches for assessing the fate and transport of new chemicals to reflect the best-available science. Several categories of new chemicals such as per/polyfluoros compounds, nanomaterials, and metal oxide complexes have posed challenges in environmental fate assessment due to their poorly understood environmental behavior, and physical-chemical properties. In many cases, interpretation of chemical fate and transport of these new chemicals is hindered by a lack of data on the parent compound and degradants in environmental media. Additionally, the level of uncertainty in fate characterization can be attributed to the difficulty to conduct laboratory testing on the parent materials, as factors such as low to no solubility, slow or sometimes decades-long degradation reactions, and various analytical challenges complicates their environmental fate evaluation. The presentation will describe the needs, as well as the methods of RAD to assess environmental fate pathways of the above mentioned chemicals. Specifically, it will identify and address the issues associated with: 1) the behavior of these chemicals, 2) identification of degradation rates, degradation intermediates, and final products, 3) the limitations of using predictive models to assess these types of chemicals, and 4) the deficiencies in the current fate test guidelines and modifications developed in conjunction with the stakeholders. This presentation will also show various methods and continuing efforts undertaken by OPPT/RAD to resolve these issues, for instance: 1) development of in-house chemical class-specific databases for identification of known-fragments of intermediates, by-products, and end-products from the degradation of the parent compounds, 2) development of knowledge banks based on information gathering from well-established research and data of previously submitted new chemical cases to support assessments of chemicals that are outside the scope of predictive models, 3) continuous refinement of fate assessment methodologies, and 4) working collaboratively with new chemical submitters to improve testing methods, protocols, and guideline modifications.

### TP174 An approach to estimate hexabromocyclododecane (HBCD) trophic transfer in terrestrial food chains

*S. Au, USEPA / Safer Choice Program; C. Bevington, K. Eisenreich, A.A. Kennedy, D. Lynch, USEPA / Office of Pollution Prevention and Toxics*

Hexabromocyclododecane (HBCD) is a brominated flame retardant largely used in the construction industry in expanded polystyrene foam (EPS) and extruded polystyrene foam (XPS). HBCD is classified as a persistent, bioaccumulative, and toxic (PBT) chemical with the potential to undergo biomagnification in aquatic ecosysstems. Specifically, HBCD has been demonstrated to be toxic to both aquatic and terrestrial organisms in both lower and higher trophic levels, however most of the available data is for aquatic food webs; there is a knowledge gap regarding the potential for HBCD to biomagnify in birds of prey that do not consume fish. Further, biomagnification factors derived from mammal-to-bird food chains have been found to differ from those derived from bird-to-bird food chains, suggesting accessibility to different types of prey may affect HBCD trophic transfer to birds. An approach for estimating the potential of HBCD trophic transfer between terrestrial mammals and predatory birds will be presented. Specifically, data from laboratory feeding studies with rats will be used as a surrogate to estimate HBCD body burdens in small terrestrial mammals (e.g., mink and rodents). Birds of prey, such as American kestrel, typically consume small terrestrial mammals. Data from kestrel ecological toxicity studies will be used to evaluate whether the consumption of small terrestrial mammals will exceed exposure concentrations (e.g., biota monitoring data) that have been shown to result in reproductive toxicological effects in American kestrel. *Disclaimer:*

*The views expressed in this abstract are those of the authors and do not necessarily represent the views or the policies of the U.S. Environmental Protection Agency.*

### TP175 Arsenic exposure, profiles of urinary arsenic species, and polymorphism effects of glutathione-s-transferase and metallothioneins

*F. Gonzalez, University of Cartagena / Department of Research School of Dentistry; B. Johnson-Restrepo, University of Cartagena / Chemistry and the Environment Group / School of Exact and Natural Sciences; D. Sánchez-Rodas, Universidad de Huelva / Center for Research in Sustainable Chemistry; D.D. Cáceres, University of Chile / Environmental Health Program / School of Public Health; M.F. Martínez, University of Chile / Department of Basic-Clinical Oncology / Faculty of Medicine; L.A. Quiñones, University of Chile / Laboratory of Chemical Carcinogenesis and Pharmacogenetics / Department of Basic-Clinical Oncology / Faculty of Medicine*

This study assessed the effects of polymorphic variants of gutathione-S-transferase and metallothioneins on profiles of urinary arsenic species. Nineteen wells of groundwater for human consumption from the municipalities of Margarita and San Fernando, Colombia were analyzed for concentration and the lifetime average daily dose (LADD) of arsenic. Specific surveys on 101 individuals aged between 18 and 75 years old were applied to collect demographic information and other exposure factors. In addition, GSTT1-*null*, GSTM1-*null*, GSTP1-rs1695 and MT-2A-rs28366003, genetic polymorphisms were evaluated either by direct PCR or PCR-RFLP. We examined arsenic speciation through concentrations of urinary metabolites related with exposure using Atomic Fluorescence Spectrometry: inorganic arsenic (InAs) ($As^V$ and $As^{III}$), monomethylarsonic acid ($MMA^V$) and dimethylarsinic acid ($DMA^V$) and Total urinary As (TuAs). Also were calculated the ratios of arsenic metabolites as indicators of the metabolic capacity; primary methylation index (PMI) and secondary methylation index (SMI). The effects of polymorphisms were tested using a multivariate analysis, adjusted by potential confounders. The arsenic concentrations in groundwater were on average 34.6±24.7 µg/L greater than US Environmental protection Agency guideline for arsenic (10 µg/L). Was observed a significant correlation among LADD of arsenic and TuAs ($r=0.69$; $p=0.000$). %InAs was associated with GSTP1, age, BMI, alcohol consumption, LADD and the interactions GSTP1*Age, GSTP1*BMI, GSTP1*alcohol consumption ($R^2=0.43$; likelihood-ratio test, $p=0.000$). PMI was associated with GSTP1, GSTM1, sex, BMI, alcohol consumption and the interactions GSTP1*GSTM1, GSTP1*Sex, GSTP1*BMI and GSTP1*alcohol consumption ($R^2=0.20$; likelihood-ratio test, $p=0.007$). GSTP1 (AG+GG) homozygotes/heterozygotes and LADD of arsenic could increase %InAs and decrease the calculation of PMI ratio in people exposed to low and moderate levels of arsenic from drinking groundwater. However the explanatory models stronger showed the participation of some covariates that could to influence the effects of the polymorphisms on these exposure biomarkers to arsenic

### TP176 Assessing of dietary exposure risk to methylmercury in seafood in Taiwan

*M. Ling, S. Choi, National Taiwan Ocean University / Department of Food Science; P. Lin, National Health Research Institutes / National Institute of Environmental Health Sciences*

Being surrounded by the ocean, Taiwan enjoys rich and abundant aquatic resources. Seafood is the main source of dietary exposure to methylmercury (MeHg). Samples of fish, shellfish, cephalopods, crustaceans and algae were purchased from the major fish port, traditional wet markets and supermarket across Taiwan. Some of the raw sampled products were cooked. We analyzed the total mercury concentration of 151 raw samples and 141 cooked samples, and convert it to methylmercury concentration. Pelagic fish, inshore fish, other fish, shellfish, cephalopods, crustaceans and algae MeHg average concentration in raw samples was 0.61 mg/kg, 0.11 mg/kg, 0.05 mg/kg, 0.02 mg/kg, 0.02 mg/kg, 0.03 mg/kg, 0.01 mg/kg, respectively. Furthermore, MeHg average concentration in cooked samples was slightly high than the raw samples. Methylmercury concentrations are high in shark, swordfish, and tuna, but the average concentrations did not exceed the regulatory standards of Taiwan. The ratio of aquatic products that exceeded the limits for methylmercury was not high.

### TP177 Atmospheric Deposition and Toxicity Assessment of Polycyclic Aromatic Hydrocarbons (PAHs) in Ambient Air of Yenagoa and its Environs

*S.A. Uzoekwe, Federal University Otuoke, Bayelsa State / Chemical Sciences; T. Ikpesu, O.M. Ugwumba, Federal University Otuoke, Bayelsa State*

Atmospheric levels, distribution and toxicity of sixteen (16) USEPA priority PAHs in ambient air of Yenagoa communities were evaluated using USEPA method 8015B. Among the PAHS determined, benzo(b) fluoranthene was found to be the most abundant compound at all sites totally 116 16.06 $gKg^{-1}$ or 29.09%, followed by benzo(a) anthralene (85.0 14.02 $gKg^{-1}$; 21%), Chrysene (51.0 7.50 g /Kg; 12.88%), Fluoranthene (49.0 4.7 $gKg^{-1}$; 12.37%, phenanthrene (21.0 7.5, $gKg^{-1}$; 5.3%) anthialene (9 2.81; 2.3%)etc. Some of the pollutants like benzo(a)pyrene, dibenzo (a.h) anthracene and benzo (g,h,l) perylene are found to be low or negligible in most of the locations. Generally, the PAHs concentrations of PAHs determined at different sites in increased markedly in this order: AQBJ>AQOG>AQTR> AQIM> AQOT>AQGU. Multivariate analysis including principal component analysis (PCA) and Correlation Matrix (CR) showed that three major factors (industrial activities including gas flaring, traffic/commercial activities and biomass combuastion) were responsible for the concentrations measured and sites with similar activities correlated well. Factor 1 with Eigen value of 3.7268 accounted for 62.1% variance, factor 2, 17.7% and factor 3, 17.7%. Hierarchical cluster analysis identified two main clusters: AQOT location used as the control and others. Similarly, source diagnostic ratios revealed that PAHs load in AQOT is of pyrogenic origin and others mainly petrogenic origin. Finally, risks posed by these pollutants to the inhabitants of these communities were calculated and the results expressed in terms of hazard quotient (HQ) (Pyrene 1.0 anthracene 0.87; fluoranthrene O.35; napthanlene 0.1) and 'excess life cancer risk' (ELCR) (dibenzo (a,h) anthracene $1.27x10^2$; benzo(a)anthracene $14.6x10^{-1}$; indeno (1,2,3-cd) pyrene $4.2x10^{-1}$; benzo(k)fluoranthene $1.7x10^{-1}$ and chrysene $2.1x10^{-3}$) for non-cancer PAHs and carcinogenic PAHs respectively.

### TP178 Changes of exoskeleton surface roughness and chitinase gene expression in the mud crab following the antifouling biocide irgarol

*K. Park, Chonnam National University / Department of Fisheries and Ocean Science; C. Nikapitiya, Chonnam National University / Department of Aqualife Medicine; W. Kim, Chonnam National University / Faculty of Marine Technology; T. Kwak, GNTECH / Department of Mechanical Engineering; I. Kwak, Chonnam National University / Faculty of Marine Technology*

Irgarol is a common antifoulant present in coastal sediment. The mud crab *Macrophthalmus japonicus* is one of the most abundant of the macrobenthos in the costal environment, and its exoskeleton has a protective function against various environmental threats. We evaluated the effects of irgarol toxicity on the exoskeleton of *M. japonicus*, which is the outer layer facing the environment. We analyzed transcriptional expression of exoskeleton, molting, and proteolysis-related genes in the gill and hepatopancreas of these exposed *M. japonicus*. In addition, changes in survival and exoskeleton surface characteristics were investigated. In the hepatopancreas, mRNA expression of chitinase 1 (*Mj-chi1*), chitinase 4 (*Mj-chi4*), and chitinase 5 (*Mj-chi5*)increased in *M. japonicus* exposed to all concentrations of irgarol. *Mj-chi1* and *Mj-chi4* expressions from 1 to 10 µg $L^{-1}$ were dose- and time-dependent. Ecdysteroid receptor (*Mj-EcR*), trypsin (*Mj-Tryp*), and serine proteinase (*Mj-SP*) in the hepatopancreas were upregulated in response to different exposure levels of irgarol at day 1, 4, or 7. In contrast, gill *Mj-chi5*, *Mj-Tryp*, and *Mj-SP* exhibited late upregulated responses to 10 μg $L^{-1}$ irgarol compared to the control at day 7. *Mj-chi1* showed early upregulation upon exposure to 10 μg $L^{-1}$ irgarol and *Mj-chi4* showed no changes in transcription in the gill. Gill *Mj-EcR* presented generally downregulated expression patterns. In addition, decreased survival and change of exoskeleton surface roughness were observed in *M. japonicus* exposed to the three concentrations of irgarol. These results suggest that exposure to irgarol induces changes in the exoskeleton, molting, and proteolysis metabolism of *M. japonicus*.

**TP179 Comparative Evaluation of Agricultural Pesticide Usage in Knights Landing and Capay Valley, California**

*T. Jow, D. Moher, S. Somepalle, J.S. Kelty, N. Vu, K. Prado, A. Aranda, N. Deeb-Sossa, UC Davis; L. Van Winkle, UC Davis / Center for Health and the Environment*

Knights Landing (KL) and Capay Valley (CV) are both communities in Yolo County surrounded by agricultural fields, but CV specializes in organic crops. KL residents expressed concerns about elevated exposure to potential carcinogens due to proximity of agricultural pesticide applications and they invited UC Davis researchers to further investigate. This study quantifies the amount of applied pesticides, carcinogenicity of pesticide active ingredients, crop-specific pesticide application, and method of application longitudinally from 2011-2015 in KL and CV. Pesticide application reports were retrieved from the Pesticide Information Portal (PIP) from the California Department of Pesticide Regulation. The weight of pesticide applied was normalized to total acreage in the 2 KL and 3 CV zip codes included in the PIP data. Carcinogenic chemicals were identified using the USEPA Standard Evaluation of Pesticides for Carcinogenic Potential and the IARC Monographs. We found that four times more total pesticides by weight and eight times more carcinogenic pesticides by weight were applied in KL compared to CV. Therefore, KL community exposures to agricultural pesticides are potentially higher than CV, supporting the concerns raised by the KL community members.

**TP180 Consideration of Skin Sensitization in Identifying Preservatives for the USEPA's Safer Chemical Ingredients List**

*C. Rudisill, K. Salinas, J. Melia, H. Carlson-Lynch, SRC, Inc. / Environmental Health Analysis; L. Morlacci, SRC, Inc.*

The USEPA Safer Chemical Ingredients List (SCIL) identifies safer ingredients using robust, transparent and publicly available criteria for several functional use classes including preservatives. Chemicals meeting these criteria are listed on the SCIL and can be used in Safer Choice-certified products. Preservatives play a critical role in consumer products by guarding against microbial contamination and degradation. They pose a challenge for formulating with safer chemistries due to their inherent bioactivity, which may produce unintended toxicity. Recent news reports concerning preservatives in consumer products has focused on cases of dermal allergic reactions. Currently, there are 31 preservative chemicals listed on the SCIL, which are allowed in Safer Choice-certified products. They are marked based on overall confidence in the hazard profile, with either a green circle (N = 22, verified low concern), green half-circle (N = 2, low concern but needs additional data), and yellow triangle (N = 7, some hazard concerns but represents best in class for the function). This marking reflects an overall finding based on 10 hazard endpoints, including but not limited to skin sensitization. A curated database of experimental data for preservatives was created using publicly-available secondary sources describing clinical studies in humans and experimental animal model of skin sensitization (e.g., local lymph node assay [LLNA], guinea pig maximization test). Primary sources were consulted when discrepancies necessitated an in-depth review. Analog data were used to evaluate endpoints with experimental data gaps. In some cases, a weight of evidence evaluation was used to address data sets with mixed results (e.g., positive clinical data, negative animal data). The majority of green circle preservatives are of low concern for skin sensitization. The half-green preservatives currently lack a reliable dataset to evaluate skin sensitization. The yellow triangle preservatives generally have some positive skin sensitization data, but represent best in class when compared to other preservatives with known sensitization issues. As per Safer Choice criteria, preservatives in Safer Choice-certified products are allowed at the lowest possible effective level. The results of this evaluation demonstrate how SCIL status can be used to select safer preservatives for consumer products.

**TP181 Current State of Cleanup Levels and Approaches for Petroleum-Contaminated Sites**

*M. Pattanayek, Integral Consulting Inc*

Risk evaluations for petroleum release sites present complex and unique challenges to site managers, risk assessors, regulators and other stakeholders. Risk characterization based on total petroleum hydrocarbon (TPH) concentration measurements in different environmental media may be used for risk-based corrective actions at petroleum release sites. However, chemical compositions of petroleum hydrocarbon mixtures are complex and subject to change over time due to fate and transport processes. While methods to characterize risk for individual constituents are well accepted, methods to assess cumulative risk posed by the multitude of petroleum-related compounds typically included under the term "TPH" have yet to be widely accepted and employed. This is compounded by inconsistencies between published guidance for the risk-based assessment of TPH-related compounds and requirements for expensive laboratory tests that might not be available in many areas of the country. Better guidance is needed to help states develop consistent methodology for establishing risk-based cleanup levels and for establishing and approving methods for risk-based corrective action. A state survey was conducted by the Interstate Technology and Regulatory Council (ITRC) TPH Risk Evaluation at Petroleum-Contaminated Sites Team. A total of 53 complete responses were recorded from 44 states (a few with multiple programs), Washington D.C., and Puerto Rico. The goal of the survey was to collect information on state agencies' use of TPH data within their regulatory programs and to help develop the ITRC technical and regulatory (Tech Reg) guidance that describes best practices for evaluating TPH risk. This presentation will highlight the various approaches used by different states and programs, analysis of the survey results, and its implementation in the ITRC Teg Reg guidance.

**TP182 Data Gap Filling with ECOSAR and Application to K-REACH Compliance for Environmental Risk Assessment**

*J. Ra, Korea Institute of Industrial Technology / Regulatory Chemical Analysis & Risk assessment Center; S. Ok, Hanyang University / Department of Marine Science and Convergence Engineering; H. Moon, Hanyang University / Marine Sciences and Convergent Technology*

USEPA/OPPT developed ECOSAR model and still updated for hazard and risk assessment to chemicals under the TSCA. It is a QSAR model and used for data gap filling of lack or no experimental measured data chemicals in TSCA. This model consider chemical class based on structure as well as toxicity mechanisms. As a screening level tool, it is also used to other chemical regulations like EU REACH, South Korea K-REACH. We applied ECOSAR (v2.0) to estimate aqatic toxicity to fill data gaps to establish SSDs of 20 organic chemicals. However, it is an old tool firstly developed in 1990s. Therefore, it is need to check whether ECOSAR still shows estimation capacity considering new toxicity data. We investigated ECOSAR estimation capacity before applying to the K-REACH compliance. We targeted 35 organic chemicals as the lack of toxicity data of 20 chemicals and compared the each chemical geometric value to ECOSAR predictions. We collected toxicity data at ECOTOX database and calculated species mean toxicity value with SD(standard deviation). We applied ECOSAR model if we found data gap in K-REACH compliance like risk assessment. Model applicability was evaluated by comparing model output and experimental data, where we focused on the SD of experimental data. For regulatory purpose, we consider lower toxicity range (high toxicity than experimental) like -1SD, -2SD, and -3SD, which are conservative range. However, upper and lower toxicity range are considered for toxicity estimation. As a result, ECOSAR fish toxic estimation of 18 chemicals show appropriate for regulatory purpose. Among 18 chemicals, 4 chemicals show highly conservative (between -2SD and -3SD or -3SD outline), but these are not suite for toxic estimation (between +2SD and +3SD or +3SD outline). 5 chemicals are moderately conservative (between -1SD and -2SD) and these are moderately toxic prediction (between +1SD and +2SD). Then 9 chemicals are in -1SD, which are not suite for regulatory purpose (slightly conservative), but fish toxic estimation is highly predictive (in +1SD). Organic chemical class of that 9 chemicals are Neutral organic(3), Phenol(2), Halide(3), and Aniline(1). As a conclusion, ECOSAR may not appropriate to some chemical class for regulatory purpose. However, we investigated limited number of groups and chemicals. Therefore, in further study, we are going to expand the number of chemical groups and associated chemicals to clarify model applicability to K-REACH in risk assessment

**TP183 Defining Substances of Concern for Environmental Risk Assessment based on European Guidance**

*A. Pastirik, W.E. Hillwalker, SC Johnson / Global Safety Assessment & Regulatory Affairs; P. Mason, SC Johnson EurAFNE Limited / GSARA; D. Feifarek, SC Johnson / GSARA*

Consumer product manufacturers evaluate the hazard profile of ingredients used in their products to ensure safety and meet regulatory requirements. The Guidance on the Biocidal Products Regulation (BPR) released by the European Chemical Agency (ECHA) in October 2017, defines parameters for identification of Substances of Concern (SOC) in biocidal products. In general, these parameters include hazard and concentration criteria. Among other purposes, SOCs are selected for environmental risk assessments of mixtures. An overview of how this guidance impacts environmental risk assessment of a biocidal product will be provided. A process will be proposed to screen chemicals based on their toxicological properties to determine the likelihood of being flagged as an SOC. Additionally, applicability of the guidance for chemical selection when assessing mixture toxicity in non-biocidal products will be analyzed.

**TP184 Development and application of a multidimensional density dependent matrix population model for Atlantic killifish (*Fundulus heteroclitus*)**

*D.H. Miller, USEPA / Mid-Continent Ecology Division; B.W. Clark, D.E. Nacci, USEPA / Atlantic Ecology Division*

Modeling exposure and recovery of fish and wildlife populations after stressor mitigation serves as a basis for evaluating population status and remediation success. The Atlantic killifish (*Fundulus heteroclitus*) is an important and well-studied model organism for understanding the effects of pollutants and other stressors in estuarine and marine ecosystems. Herein, we develop a multidimensional density dependent matrix population model for Atlantic killifish that analyzes both size class structure and age class structure of the population simultaneously over time. This population modeling approach emphasizes application in conjunction with field monitoring efforts (e.g., through effects-based monitoring programs) and/or laboratory analysis to link effects due to chemical and/or nonchemical stressors to adverse outcomes in whole organisms and populations. We applied the model to investigate population trajectories for Atlantic killifish exposed to 112, 296, and 875 pg/g of 2,3,7,8-tetrachlorodibenzop-dioxin with effects on fertility and survival rates. For each exposure concentration of 2,3,7,8-tetrachlorodibenzop-dioxin, the corresponding plots of total population size, population size class structure, and population age class structure over time were generated. For example, exposure to 875 pg/g of 2,3,7,8-tetrachlorodibenzop-dioxin resulted in a 13.1% decline in population size after 2 years, a 19.9% decline in population size after 5 years, and a 27.9% decline in population size over 10 years with plots of all size classes and age classes exhibiting declines. The present study serves as an example of how multidimensional density dependent matrix population models are useful tools for ecological risk assessment because they integrate effects across the life cycle, provide a linkage between endpoints observed in the individual and ecological risk to the population as a whole, and project outcomes for future generations.

**TP185 Development of an EPA GIS Mapping Tool for Accessing Estimated Water Chemistry Parameters to Support Criteria Implementation**

*A. Harper, G. Arielle, USEPA / Office of Water; L. Cruz, USEPA / HECD; K. Gallagher, B. Behl, USEPA / Office of Water*

EPA has developed a mapping tool for states, tribes, and other users to locate estimated water chemistry parameters for their input into a biotic ligand model, multiple-linear regression, or hardness based metals-criteria model when there is insufficient water chemistry data available at a given site. These estimated parameters are based on data contained in draft "Biotic Ligand Model Missing Parameters Technical Support Document" (EPA 820-R-15-106), now updated with additional information. This product is intended to support the development of criteria that rely on the use of water chemistry parameters (temperature, pH, dissolved organic carbon, alkalinity, calcium, magnesium, sodium, potassium, sulfate, and chloride) by providing a user-focused and visual representation of the information found in the draft Biotic Ligand Model Missing Parameters Technical Support Document. Users will be able to locate a site's estimated parameters at the Level 3 ecoregion and can search for a location via NWIS station number, NPDES permit number, location name or coordinates, and ecoregion. Users can click on an area of the map to access a site's estimated water chemistry data. Measured water quality data, such as geochemical ions (Cl, $SO_4^{-2}$, Na, Mg, Ca, K, carbonate/alkalinity), DOC, conductivity and stream order were retrieved from the United States Geological Survey National Waters Information System (USGS-NWIS) stations for rivers and streams between 1984 and 2018. GIS data was used to locate each NWIS sampling location at the Level 3 Ecoregion, based upon the latitude-longitude spatial coordinates. GIS was also used to assign the Strahler stream order to each NWIS sampling location. Measured values for the water chemistry parameters are used as attributes of each NWIS station and the station is plotted on US map. DOC concentration are from the *National Bioaccumulation Factors Technical Support Document* (EPA-822-R-03-030). EPA prefers the use of current, site-specific, water chemistry data when available but has provided this tool for instances when sufficient data to run a model is lacking.

**TP186 Disrupting effects of antibiotic sulfathiazole on developmental process during sensitive life-cycle stage of *Chironomus riparius***

*K. Park, Chonnam National University / Department of Fisheries and Ocean Science; I. Kwak, Chonnam National University / Faculty of Marine Technology*

Antibiotics in the environment are a concern due to their potential to harm humans and interrupt ecosystems. Sulfathiazole (STZ), a sulfonamide antibiotic, is commonly used in aquaculture and is typically found inaquatic ecosystems. We evaluated the ecological risk of STZ by examining biological, molecular and biochemical response in *Chironomus riparius.* Samples were exposed to STZ for 12, 24 and 96 h, and effects of STZ were evaluated at the molecular level by analyzing changes in gene expression related to the endocrine system, cellular stress response and enzyme activity of genes on antioxidant and detoxification pathways. STZ exposure induced significant effects on survival, growth and sex ratio of emergent adults and mouthpart deformity in *C. riparius*. STZ caused concentration and time-dependent toxicity in most of the selected biomarkers. STZ exposure leads to significant heat-shock response of protein genes (HSP70, HSP40, HSP90 and HSP27) and to disruption by up-regulating selected genes, including the ecdysone receptor gene, estrogen-related receptors, ultraspiracle and E74 early ecdysone-responsive gene. Furthermore, STZ induced alteration of enzyme activities on antioxidant and detoxification responses (catalase, superoxide dismutase, glutathione peroxidase and peroxidase) in *C.riparius*. By inducing oxidative stress, antibiotic STZ disturbs the endocrine system and produces adverse effects in growth processes of invertebrates.

### TP187 Evaluating *E.coli* exposure to anglers of the Pine River (Michigan)

*H. Wilson, Alma College / Environmental Studies; A.D. Harwood, Alma College / Environmental Studies / Biology*

Former research conducted by the Alma College Department of Environmental Science and the Michigan Department of Environmental Quality has confirmed the presence of thermo-tolerant fecal coliform bacteria including *E. coli* in the Pine River, a tributary of the Chippewa River in Gratiot County, MI. Although signage recommends limited contact with the water, fishing from the Pine River is common practice. Since the presence of *E. coli* and other fecal coliform bacteria has the potential to cause human illness, it is important to determine if contact with water via fishing activities can expose anglers to *E. coli*. A study conducted in 2016 found that these bacteria accumulated on caged hatchery fish in the river, particularly after rain events. The presence of bacteria on native fish, however, was unknown. The current study addresses the presence of thermo-tolerant *E. coli* on resident Pine River fish, as well as evaluates the potential for these bacteria to occur on the hands of recreational anglers. Multiple locations along the river north of the Alma dam were sampled for the presence of *E. coli*. Angled fish and hands of volunteer anglers were swabbed at various time intervals to confirm the presence of these bacteria on the fish and on the hands of anglers. In the laboratory, the bacteria were expelled from the sample swabs and incubated prior to quantification. Fecal coliform bacteria and *E. coli* were present on both the resident fish and the hands of anglers. Fecal coliform bacteria occurred on 100% of the participating angler's hands, and nearly 80% had *E. coli* present on their hands regardless of their interaction with a fish. Therefore, anglers fishing in the Pine River may be exposed to potentially harmful bacteria.

### TP188 Evaluating Environmental Circumstances Representing Critical Conditions for Metals Criteria Applying the BLM – Copper as a Case Study

*L. Cruz, USEPA / HECD; J.R. Beaman, M. Elias, USEPA / Office of Water; J. Justice, USEPA / HECD; K. Gallagher, USEPA / Office of Water*

The USEPA Health and Ecological Criteria Division evaluated how water physiochemical conditions that affect metal bioavailability relate to stream flow by pairing corresponding measured 2007 copper Biotic Ligand Model (EPA-822-R-07-001) input parameters and stream flow. Relationships between streamflow and parameters that influence metal bioavailability may identify potential high-risk scenarios (i.e., "critical conditions") where metals are relatively bioavailable and toxicity reduction capacity is limited. Paired measurements of stream flow and BLM input parameters (i.e., calcium, magnesium, sodium, potassium, chloride, sulfate, sulfide and carbonate/alkalinity, pH, DOC, temperature, conductivity) were collected from the US Geological Survey National Water Information System (NWIS) for dates between 1984 and 2018. Data for hardness, stream order, presence/absence of dischargers, level III ecoregion, season, weather conditions, and the spatial coordinates of each sampled station were also collected. BLM input parameters were used to predict instantaneous water quality criteria (IWQC), as a surrogate measure of copper bioavailability, that could be paired to stream flow measurements. Paired IWQCs and stream flow measurements for each sampling location were analyzed to explore site-specific relationships between stream flow rate and copper bioavailability (measured as IWQC) using least squares regression. The relationship between stream flow rate and IWQC was negative for 68% of locations, indicating metal bioavailability was greater at higher stream flow rates. However, copper was also highly bioavailable (as indicated by relatively low IWQC values) across a range of stream flow rates, suggesting additional factors besides stream flow may influence the presence of ligands that affect copper bioavailability. Further analysis is underway to assess how season, stream order, ecoregion, land use, and presence/absence of point sources influence the binding ligands which, in turn, affect copper bioavailability.

### TP189 Evaluating Environmental Risk on an Inundated Dam Construction Staging Area

*B. Gardiner, US Army Corps Engineers / Engineering and Technology; K. Haskins, A. Burcham, K. Kerns, US Army Corps of Engineers*

A baseline human health/ecological risk assessment is being conducted as part of the remedial investigation (RI) for a former construction staging area in the Big Cliff Reservoir on the North Santiam River, Oregon, USA. The Site is a former work area used to support the construction of Big Cliff and Detroit Dams through 1953. The area is now submerged within the Big Cliff Reservoir following the commissioning of the Big Cliff Dam. Legacy wastes associated with historic construction debris were evaluated as potential sources of sediment contamination. Surface and subsurface samples were collected from 31 randomly selected stations and 53 locations targeting areas with visible signs of contamination (e.g. debris, staining). Based on land use history and preliminary data, samples were analyzed for a metals, polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), and other SVOCs. RI results indicated that while there was not widespread contamination across the site, there were locations with concentrations of selected metals, PAHs and PCBs above ecological screening levels; human health COPCs were limited to antimony, arsenic, and lead. Contaminant distribution was highly localized, with different chemical suites elevated above screening levels at different locations throughout the site. These localized areas of contamination are likely the result of specific industrial releases that occurred prior to inundation while the site was terrestrial. This limits the likelihood for diffuse lateral contamination typical of more traditional sediment contamination. Additionally, the substrate is highly compacted sand and gravel limiting sediment redistribution across the site. Due to the unusual nature of the site and the localized contaminant distribution, a traditional risk assessment approach using sitewide 95UCL values overestimated risk. Rather the risk assessment was conducted using a step-wise approach, selectively removing stations with the highest concentrations of COPEC/COPCs from consideration based on the assumption that sediment represented by these samples would be remediated or removed. This site-specific approach allowed for the identification and removal of localized and bounded areas of increased contamination that were driving risk, informing and limiting the scope of the feasibility study. This is an approach that may have application for other similar former dam construction staging areas that have been subsequently inundated.

### TP190 Evaluation of the occurrence of fluoroquinolones drugs in river water by liquid chromatography

*L. Silva, Federal Institute of Maranhao / Departament of Chemistry; N. Mesquita Brito, Institute Federal do Maranhao-IFMA / DAQ; K.M. Araujo, R.A. Dias, R.L. Jesus, A.D. Ferreira, M.S. Diniz, Federal Institute of Maranhao; G.S. Silva, Federal Institute of Maranhao / Department of Chemistry*

Antibiotics are an important class of pharmaceuticals that have been found in water samples and fluoroquinolones (FQs) are an example of this group. Even in low concentrations, they are able to impact the aquatic system because may further increase resistance of pathogenic bacteria. In view of this problem, this study aims to investigate the presence of FQs drugs such as levofloxacin (LEV), ciprofloxacin (CIP), enrofloxacin (ENR), sarafloxacin (SAR) and norfloxacin (NOR) in water samples from Anil River, located in Sao Luis, Maranhao, Brazil. The research was developed at Federal Institute of Maranhao, using samples collected on May and December 2017 from river in different days and in two places (A and B), according to National Water Agency (ANA) recommendations, stored in amber glass bottles and refrigerated at 2 °C for 24h. Before being analyzed, the pH were adjusted to 3 with $H_3PO_4$, afterward the samples were filtered and prepared by solid-phase extraction process with HLB® Oasis cartridges. The obtained sample extract was dried using nitrogen and then reconstituted in mobile phase used on chromatographic process. The analyses were performed on a Shimadzu LC20-AT high performance liquid chromatograph equipped with a Shimadzu RF-20A fluorescence detector, using a Luna C18 column (250mm x 4.6 mm;

5 μm), flow rate 1.2mL/min, temperature column at 35 °C, excitation wavelength of 280nm and emission wavelength of 450nm, mobile phase was methanol and buffer (0.04M $NaHPO_4$, pH 3) in gradient mode. Two FQs (ENR and SAR) were not found on May and December samples but all revealed contamination by at least one of others in a range of concentrations 15.8-100.6 μg.L-1 (LEV), 11.4-112.7 μg.L-1 (CIP) and 10.3-67.7 μg.L-1 (NOR). LEV was not found on place A, NOR was detected in all samples and CIP was present in May on both places and only on place A in December. The presence of LEV, CIP and NOR antibiotics confirms the contamination on Anil River by domestic sewage, because these drugs are widely used in several types of human infections. The absence of ENR and SAR probably is due to they are exclusively used in veterinary medicine and activities involving animal husbandry are not be so prominent in the collection region. The results demonstrates the importance of effective actions against contamination on rivers by domestic sewage, since they could have compounds such as fluoroquinolones, that may cause a strong negative impact to aquatic organisms.

**TP191 Exposure assessment of environmental phenols by cosmetic products to Korean adolescent girls**

*J. Lee, Department of Environmental Engineering / Seoul National University of Science and Technology; S. Kim, School of Public Health / Seoul National University / Department of Environmental Health Sciences; H. Moon, Hanyang University / Marine Sciences and Convergent Technology; K. Choi, Seoul National University / Environmental Health Sciences; K. Kim, Seoul National University of Science and Technology / Environmental Engineering*

Cosmetics usage of the Korea adolescent girls is increasing, and the average age of use is decreasing. Environmental phenols are suspected endocrine disrupting chemicals (EDCs) and widely used as a preservative in cosmetics and personal products. This study was conducted to analyze exposure levels of environmental phenols such as 6 parabens (MeP, EtP, PrP, BzP, BuP, and HeP), triclosan, and 4 benzophenones (BP-1, BP-2, BP-3, and, BP-8) in urine to adolescent girls (aged between 13-17 years old, and n=123). We recruited from middle and high schools in Korea. In addition, the participants in the intervention study (n=84) were instructed not to use all cosmetics for 48 hours, except cleansing products to identify the factors that contributed to the exposure source or exposure more precisely. The detection rates and mean concentrations of urine samples were MeP (100%, 75.8 ng/mL), EtP (100,58.4), PrP (90, 11.2), BuP (26, 0.2), BzP (29, 0.01), HeP (4, 0.2), triclosan (71, 1.0), BP-1 (99, 0.6), BP-2 (6, 0.1), BP-3 (55, 1.1), and BP-8 (5, 0.02). The EtP showed higher concentrations, whereas benzophenones and triclosan had lower levels than other countries. In the intervention study, the mean concentrations of the 3 parabens (MeP, PrP, and, BuP) in the urine decreased by 17, 41, and 13%, respectively, whereas the mean concentration of EtP, BzP, and triclosan increased after the intervention. Among participants whose exposure levels decreased after the intervention, the concentration of BP-3 in urine decreased by 26%, and the exposure level of EtP was reduced by up to 72%. As a result, we found that cosmetics contributed to exposure to environmental phenols.

**TP192 Exposure to heavy metals in informal workers in Cartagena, Colombia**

*F.V. Murillo, Cartagena University / Exact and Natural Sciences School; K. Martinez-Yanez, University of Cartagena / Grupo de Química y Medio Ambiente; S. Mendoza-Caro, University of Cartagena / Environmental Chemistry Research Group, School of Exact and Natural Sciences; A. Fortich-Revollo, Cartagena University; B. Johnson-Restrepo, University of Cartagena / Chemistry and the Environment Group / School of Exact and Natural Sciences*

Metals such as lead and cadmium some elements that are used as part of the great forces that move the world in applications including batteries, electronic components, and other important industrial and technological uses. However, exposure to heavy metals is a public health problem, the concentration in blood and other biological fluids are currently the main bioindicators. In Colombia, there is an important informal or artisanal worker population which is vulnerable to poisoning with heavy metals because it does not use the appropriate protection elements and these workers did not have environmental education. The main routes of entry to the body are the respiratory, digestive and percutaneous. High exposure to lead and cadmium can cause hematological disorders, toxic effects on the central nervous system, toxic changes and the function of various organs. The objective of this study is to determine the lead and cadmium levels in blood (PbLB) and (CdLB) in informal worker including fishermen, welders, painters, battery recycler, and automobile mechanics, and electronic technicians. To achieve this purpose, 277 blood samples were collected from informal worker over 18 years of age with their respective informed consent in Cartagena, Colombia. PbLB and CdLB were quantified by graphite-furnace atomic absorption spectrophotometry (GF-AAS) with Zeeman background correction. Hematological parameters, lipid profile, and glycaemia were also determinate in blood samples.PbLB and CdLB correlates with the year in experience and weight, height, body mass index, as well as evidence in the basophilia peripheral blood smear. These results shown that most of the informal workers have considerable lead concentration above 5 μg /dL. The average concentrations in μg/dL ±standard deviation (range) were of PbLB in battery repairers: 7.1±16.8(0.1-72.8), fishermen: 11.3±13(0.4–53.7), electricians technicians: 9.1±16.1(0.4-53.3), mechanics: 9.2 ± 16.3(0.4-51.3), painter 4.3 ± 4.1 (0.9 -11.7), and welders : 3.8 ± 1.2(1.9-8.0), however the average concentration in μg/L of CdLB were in battery repairers: 1±0.8(0.1-3), fishermen: 1.5±0.9(0.14–5.7), electricians technician: 2.2±1,7(0.1-5.0), mechanics: 2.3 ± 16.3(0.3-7), painters 1,3 ±1,4 (0,2-5), and welders : 1.5 ±1.6(0.4-12.8). Therefore, it is concluded that, e-waste recycling activities release heavy metals into the atmosphere including air, soil, dust etc., which causes adverse health effects on the workers.

**TP193 Historical Trends of Polychlorinated Biphenyls in Chesapeake Bay Fsh and Implications for Human Exposure**

*T. Needham, U. Ghosh, University of Maryland Baltimore County / Chemical, Biochemical, and Environmental Engineering*

The Chesapeake Bay watershed represents an important national resource for industry, commercial fishing, and recreation spanning six states and the District of Columbia. Polychlorinated biphenyl (PCB) exposure through fish consumption from the Bay continues to pose a risk to human health despite the ban on commercial PCB use in 1979 and remediation efforts for historically contaminated sites throughout the watershed. The objectives of this study were to: 1) provide historical perspective on PCB body burden in fish caught in the Chesapeake Bay watershed; 2) determine whether PCB body burdens in fish decreased over the 16-year sampling period; 3) evaluate the possible impacts to human health through fish consumption from the Chesapeake Bay. Fish tissue concentrations were measured from 1999 to 2016 as part of the Maryland Department of the Environment's fish monitoring program. White perch, channel catfish, and striped bass were selected for comparison based on the availability of data, frequency of sampling, and importance as both a commercial and recreational fish species. Data were compiled and sorted by drainage basin, species, and sampling year, resulting in the selection of seven drainage basins of interest to assess historical trends. Total PCB body burdens for individual fish composites ranged between 2.48 and 2,936 μg/kg with annual average values ranging between 8.52 and 1,522 μg/kg. Based on the results of our study, less than half of the assessed drainage basins showed statistically significant decreases in fish body burdens, with significant numbers indicating body burdens above the 39 μg/kg threshold for increased risk to human health via subsistence fishing.

**TP194 Honey bee risk assessment: Are two larval studies better than one?**

*M. Feken, Syngenta / Ecological Risk Assessment; R. Layton, Arysta LifeScience North America; D.R. Schmehl, Bayer US / Environmental Safety; R. Singh, BASF Corporation / Ecotoxicology*

After the publication of the Guidance for Assessing Pesticide Risk to Bees (USEPA, PMRA, CDPR 2014), USEPA began requesting a suite of honey bee Tier 1 laboratory toxicity studies to support registration and the registration review process of new and currently registered crop protection chemicals, respectively, including the 8-day acute, single exposure and the 22-day chronic, repeat exposure larval toxicity studies. For the acute larval study design (OECD Test Guideline 237), the primary goal is to determine the $LD_{50}/LC_{50}$ following a single exposure to a test chemical (on Day 4) and mortalities are evaluated on days 5-8 of the larval developmental phase. In contrast, in the 22-day chronic larval study design (OECD Guidance No. 239), honey bee larvae are exposed to the test chemical on Days 3-6 with mortality recorded on Days 4-8 during the larval phase, on Day 15 during the pupae phase, and on Day 22 during adult emergence. Given the 22-day larval study design covers all phases of honey bee brood development up to adult emergence and the larval $LD_{50}/LC_{50}$ can be calculated, the European Food Safety Authority (EFSA) prefers this study design over the acute single exposure study design. However, USEPA requires the acute, single exposure study to calculate a dose-based endpoint (i.e., $LD_{50}$) that can be incorporated into the current screening-level risk assessment model (i.e., BeeREX). There are several complications in using the acute larval study design in a risk assessment including: 1) a true daily dose cannot be determined given that provisioned diet is not entirely consumed within the 24-hour period, 2) food consumption is not consistent over the larval development period and 3) the single dose exposure does not represent any realistic exposure scenario that might occur to larvae in a honey bee colony. A preliminary review of $LD_{50}/LC_{50}$ endpoints from both study designs indicate that similar endpoints are derived based on dose (i.e., $LD_{50}$s) for both study types but lower endpoints (greater sensitivity) are typically derived in the repeat exposure design when based on concentration ($LC_{50}$s). We propose that the acute, single exposure study design should not be required for the Tier 1 risk assessment and that the risk to bee larvae should be determined from the test concentration rather than dose using the 22-d larval study.

**TP195 Household Pesticide and Heavy Metal Measurement in Knights Landing and Capay Valley, California**

*J.S. Kelty, T. Jow, D. Moher, S. Somepalle, G. Lebrec, UC Davis; T.M. Young, University of California, Davis / Civil and Environmental Engineering; N. Vu, K. Prado, A. Aranda, N. Deeb-Sossa, UC Davis; L. Van Winkle, UC Davis / Center for Health and the Environment*

Background: Environmental exposures in small farming communities of Yolo County are not well quantified. Monitoring data, epidemiologic studies, and qualitative studies suggest potentially high residential exposures to carcinogens in Northern Yolo County. Our community-based participatory research project was developed with steady community oversight to address gaps in exposure data. We quantified levels of pesticides and metals in household dust and tap water supplied by private wells in both Knights Landing and Capay Valley. Knights Landing is a conventional farming area and the comparison community, Capay Valley, is a predominantly organic growing region. We expect to detect both pesticides and heavy metals in the tap water and dust from these communities with higher concentrations in samples from Knights Landing than Capay Valley. Methods: Pesticide application data obtained from CA Pesticide Information Portal for 2011 to 2015 was used to identify peak application periods of possibly carcinogenic pesticides applied in these communities. Household dust and tap water samples from 5 homes with private wells in each community were collected during the peak Spring pesticide application period. In dust and water, pesticide concentrations were measured using both targeted and non-targeted GC-qTOF-MS and LC-qTOF-MS analysis and heavy metal concentrations were measured using ICP-MS. Consumer water quality reports for public water systems were obtained as a comparison for private wells in the area. Results: Residents in 90% of homes sampled participated in agricultural work, including one pesticide applicator. All homes were adjacent to agricultural fields. Our analysis of pesticide application data indicates ~10 fold more pesticide application in the area near Knights Landing area relative to Capay Valley with peaks in Spring planting season and Fall harvest season. Arsenic, chromium VI, and mercury contamination are of concern in the public water systems of both communities. Conclusions: Drift of pesticides applied to adjacent fields, occupational exposures, and the movement of pets may contribute to the household dust levels of pesticides. Water quality concerns are universal in both communities based on heavy metals from aquifers and pesticide runoff into surface aquifers. Water quality is especially concerning for the abundant unmonitored, unregulated private wells. Funded by UC Davis Environmental Health Sciences Center P30 ES023513 and T32 HL007013.

**TP196 Immunotoxicity of oil sands process-affected water (OSPW) and its fractions in mammalian immune cells**

*N. Phillips, D. Lillico, University of Alberta / Biological Sciences; R. Qin, M. Gamal El-Din, University of Alberta / Civil and Environmental Engineering; M. Belosevic, J. Stafford, University of Alberta / Biological Sciences*

Mining of unconventional crude oil sources such as the Northern Alberta oil sands produces large volumes of OSPW. Characterization of OSPW and its associated toxicity is a formidable challenge due to its complex and variable nature. Broadly, OSPW can be physically separated into organic (OSPW-OF) and inorganic (OSPW-IF) fractions. Naphthenic acids (NAs), phenols, and polycyclic aromatic hydrocarbons are major components of OSPW-OF, while heavy metals including mercury, lead, and arsenic, as well as salts make up OSPW-IF. Most research examining OSPW toxicity has focused on the organic fraction and NAs indicating them as the major toxic component. Previously our lab has developed and used a series of cell-based bioassays to compare whole (unfractionated) OSPW and OSPW-OF, finding that whole OSPW was significantly more toxic at NA concentrations from 10-18 mg/L, when compared to equivalent NA doses of OSPW-OF. Here, we extended the use of our in vitro bioassays to examine immunotoxic properties of OSPW-OF and OSPW-IF alone or in combination. Specifically, a murine macrophage cell-line was used to determine cell viability as well as antimicrobial responses following exposures to whole OSPW or its fractions. Viability trends were similar between OSPW-IF and whole OSPW, with both causing ~90% reductions at 17 mg/L (or volume equivalents for OSPW-IF) and producing LC50 values of ~13 mg/L. Only comparatively high NA concentrations (>100 mg/L) significantly affected cellular viability following OSPW-OF exposure. Production of antimicrobial products (e.g. reactive nitrogen intermediates) was significantly impaired in macrophages exposed to 10 mg/L whole OSPW or OSPW-IF (VE), there was no effect in cells exposed to the same doses of OSPW-OF. Preliminary assessments of the relative contributions of OSPW-OF and OSPW-IF to whole OSPW toxicity has implicated OSPW-IF as a major contributor to trends observed in altered viability and depressed antimicrobial product release by macrophages. Together, these results suggest that at NA concentrations < 20 mg/L, inorganic components play a significant role in the observed immunotoxicity of OSPW.

**TP197 Incorporation of Ecosystem Goods and Services into Ecological Risk Assessment**

*C.G. Maurice, USEPA / Office of Research and Development; B. Duncan, USEPA Region 10; S.L. Mazur, M.J. Russell, USEPA / Office of Research and Development*

Linking the benefits of the natural environment to the health and wellbeing of people has become increasingly important. Identifying, evaluating, and characterizing ecosystem goods and services (EGS) is one way to better understand this human/environment linkage. Within the USEPA Superfund and RCRA hazardous waste site cleanup processes, ecological risk assessment (ERA) is the mechanism by which threats to non-human ecological receptors are evaluated. Sometimes it is difficult to determine or communicate the benefits provided to people by the identified ecological receptors. We believe for some cases, incorporating EGS methodologies and tools into ERAs can be a useful approach to link the benefits to people provided by the environment. Depending on the circumstances, EGS can be incorporated throughout the ERA or during selected steps.

**TP198 Influence of physical parameters in human health risk assessment in areas contaminated by PAHs**

*B. Hacon, AECOM Environment / Remediation Services; A. Soares, AECOM Environment; E. Vargas, Puc-Rio*

In Brazil, health risks resulting from exposure to chemical compounds have been addressed in 2009, when federal Resolution CONAMA 420 was published. Despite this, in 2015 only three out of 26 Brazilian states followed the Resolution. The reasons for this are varied, but the one that stands out is the cost of environmental studies for site investigation. Understanding which parameters for the transport of contaminants and human health risk assessment (HHRA) are the most relevant and require more studies is essential for a broad comprehension of the case with optimization of invested resources. The objective of this study was to identify the physical parameters that exert greater influence on the results of human health risk in a scenario of contamination by polycyclic aromatic hydrocarbons (PAHs). From a case study of an area contaminated with PAHs a HHRA was performed to characterize the health risk to future workers who will occupy the study area. In view of the results obtained, a sensitivity analysis of the physical parameters of the studied area hydraulic conductivity, porosity, hydraulic gradient, water depth and fraction of organic carbon (FOC) was carried out. Risk calculations were performed using the Risk Based Corrective Action methodology and sensitivity analysis was performed using the one-at-a-time method. Parameters were varied positively and negatively, at intervals of 25%. Simulations were performed for four different exposure pathways (direct contact with soil, direct contact with groundwater, indoor and outdoor inhalation of vapors) and three distances from the source of contamination. Results showed that the physical parameter that exerted greatest influence on the results of human health risk was FOC. The variation of this parameter impacted the results for all exposure pathways, except for direct contact with the soil. It was possible to observe that the sensitivity to the variation of FOC values varies according to the distance of the source of contamination. The farther the source, the lower the sensitivity of FOC variation; and the higher the FOC the lower the risk by indoor and outdoor vapor inhalation and direct contact with groundwater. The results also pointed out the importance of soil porosity in the results of human health risk. The higher the porosity, the greater is the risk of indoor and outdoor inhalation of vapors. On the other hand, the higher the porosity, the lower the risk resulting from direct contact with water.

**TP199 Is there Value in Revising the Avian TRV for Vanadium Using Dose-Response Modeling with Existing Data?**

*C.A. Arenal, S.A. Roark, Jacobs / Environmental & Nuclear; C.J. McCarthy, Jacobs / Global Environmental Services*

Risk to avian species from exposure to vanadium (V) is often identified during screening ecological risk assessments, particularly for special-status species which are evaluated at the no-effect level. This is primarily a factor of the low avian ecological soil screening level (Eco-SSL) derived by the USEPA of 7.8 mg/kg dw. USEPA notes this value is well below typical background concentrations in the U.S. (median of 55 mg/kg eastern U.S. and 75 mg/kg western U.S.). The low no-observed-adverse-effects-level (NOAEL) toxicity reference value (TRV) used to calculate the avian Eco-SSL was 0.344 mg V/kg-bw/day, based on juvenile chicken growth. Approximately 95 percent of the avian survival, growth, and reproduction studies used to develop the Eco-SSLs were based on chickens. A push away from NOAEL and low adverse effects levels (LOAELS) towards the use of effects thresholds calculated from dose-response models is well documented. We explore whether using effects thresholds calculated from the same datasets used for NOAELs and LOAELs (where possible) would change the outcome of the Eco-SSLs. Data were compiled from the Eco-SSL dataset and additional studies conducted since the development of the Eco-SSL. Dose-response models from these published studies were used to estimate 10 percent effect dose ($ED_{10}$) and 20 percent effect dose ($ED_{20}$) thresholds. TRVs from modeled $ED_{10}$s and $ED_{20}$s were consistently higher than the TRV for the Eco-SSL, and were in the range of the geometric mean of the NOAEL values for growth and reproduction (reported in the avian Eco-SSL), which was calculated at 1.19 mg V/kg bw/day. For example, a log-logistic dose response model developed by combining V dose and egg production data from 15 chick studies resulted in $ED_{10}$ and $ED_{20}$ (and 95 percent confidence limits) of 2.0 (1.6-2.3) and 3.1 (2.7-3.5) mg V/kg bw/day. If these effects levels are used to recalculate the avian Eco-SSL, the resulting values would be 44 (36-53) and 72 (62-79) mg/kg, respectively, which is still in the range of background. We concluded that using the modeled $ED_{10}$ or $ED_{20}$ results would yield a scientifically defensible, protective, and more realistic Eco-SSL, but in the absence of data for more representative avian receptors (i.e., non-chicken species), the revised values would have limited effect in resolving the largest source of uncertainty associated with the Eco-SSL for V.

**TP200 Monitoring and Risk Assessment of Etofenprox Residue in Oriental Melon**

*J. Kim, J. Song, M. Shin, J. Seo, Korea Institute of Toxicology*

This study was conducted to monitor the residue of etofenprox in oriental melon and to assess its risk for human health. This study was carried out on three different regions and the pesticide was uniformly sprayed onto the crop at ratio of about 2.1 L/10 $m^2$ (a.i 8%) with three times at intervals of 7 days. The crops were harvested at 0, 1, 3, 5, 7 and 14 days after spraying. The samples collected were divided into two specimens (peelings and flesh) and then each sample was analyzed using LC-MS/MS after pretreatment. Analytical method was validated prior to analysis of samples, showing that method limit of quantitation (MLOQ) was 0.01 mg/kg and the results of recovery with three levels (MLOQ, MLOQ×10, MLOQ×50) ranged from 87.9% to 97.5% and relative standard deviation (RSD) was low enough to confirm the precision of analytical procedure at three different concentrations. Biological half-life was 4.8 days and most of the pesticide remained in peelings part. Based on these results, a risk assessment was calculated using a percentage of acceptable daily intake (%ADI) based on both values of EDI (Estimated Daily Intake) and ADI. %ADI was less than about 3.5%, indicating that residue level of etofenprox at harvest was considered to be safe for human health.

**TP201 Multiple lines of evidence applied for a realistic Toxic Substances Control Act ecological risk evaluation for D4 using environmental monitoring data**

*J. Nusz, Exponent, Inc.; A. Fairbrother, Exponent, Inc. / EcoSciences; J. Daley, LimnoTech; G. Burton, University of Michigan / School for Environment and Sustainability; M.E. McArdle, J.P. Staveley, Exponent*

D4 (octamethylcyclotetrasiloxane) is a high-production-volume cyclic volatile methyl siloxane with a wide range of industrial and consumer applications. A robust aquatic risk evaluation for D4 was conducted using environmental data (D4 concentrations in water, sediment, and tissues) collected under a nation-wide monitoring program facilitated under a consent agreement with the U.S. Environmental Protection Agency (EPA). The ecological risk evaluation conducted was consistent with the principles outlined in the EPA's *Guidance to Assist Interested Persons in Developing and Submitting Draft Risk Evaluations under TSCA*. The evaluation examined multiple lines of evidence (LoEs) to determine the risks from D4 to aquatic receptors in rivers and streams in the United States in the mixing zones downstream from municipal wastewater treatment plant (WWTP) discharges and discharges from manufacturing, processing, and/or formulating (MPF) facilities after onsite wastewater treatment. The risk assessment LoEs consisted of 1) comparing D4 concentrations measured in water and sediment to toxicity thresholds derived from laboratory studies; 2) comparing D4 concentrations measured in fish and benthic invertebrate tissue to a critical target lipid body burden threshold; 3) comparing fugacity-based chemical activities between laboratory-derived toxicity thresholds and measured environmental concentrations; and 4) assessing benthic macroinvertebrate community structure and habitat suitability. The approach taken moves beyond a standard deterministic hazard quotient risk approach to incorporate more advanced methods for risk prediction, including use of distributions rather than conservative point estimates of exposure to obtain a realistic view of the probability of harm. This risk evaluation concluded that there is negligible risk to water column and sediment receptors from current levels of D4 discharged from MPF facilities after onsite wastewater treatment or from municipal WWTPs that may treat a mix of industrial and consumer wastewater.

**TP202 Murine lung epithelial cell cytochrome P450 monooxygenase dependence of naphthalene toxicity in an in vitro model**

*J.S. Kelty, UC Davis; X. Ding, University of Arizona / Department of Pharmacology and Toxicology; L. Van Winkle, UC Davis / Center for Health and the Environment*

Background: Naphthalene (NA) is a ubiquitous compound found in the environment. NA is a known mouse lung carcinogen, but the carcinogenicity may not be relevant to humans and other species with lower NA metabolic potential in the airways. We developed an in vitro model of lung-liver crosstalk to test the influence of local airway epithelial cell and liver hepatocyte metabolism on the generation of toxic NA metabolites. Hepatic contribution to NA toxicity in the airway cells is expected to be significant when the local airway metabolism is impaired. Methods: Airway cells from the tracheas of wild type (WT) or *cyp2abfgs-null* female mice were cultured in Transwell inserts at the air-liquid interface (ALI). Primary mouse trachea cells were allowed to differentiate for 4 weeks. Cells were exposed to NA in media with liver microsomes from WT or *cyp2abfgs-null* female mice. Liver microsomes were boiled to inactivate P450s, as a negative control. Lung epithelial cell toxicity was measured using cell permeability and cell density. Results: Exposure of trachea cells to 5µM NA did not result in significant cell death with or without active liver microsomes. At higher doses of NA, extents of WT cell death were similar (60% drop in cell density at 20µM and 90% drop at 80µM) in cultures containing active WT, active *cyp2abfgs-null,* or boiled microsomes. Following pretreatment of epithelial cells with a P450 inhibitor, piperonyl butoxide, WT cells cultured with active WT microsomes were protected from damage (cell density loss) at 20µM, but not at 80µM, NA. *Cyp2abfgs-null* epithelial cells cultured with active WT microsomes were protected from cell death at NA exposures from 5 to 80µM. Conclusions: Airway epithelial cell NA metabolism after 4 weeks of ALI culture can contribute to toxic metabolite generation. NA airway epithelial cell toxicity in vitro occurs independently of the contribution of liver P450 metabolism for WT airways. Circulating metabolites generated by liver metabolism can contribute to mouse airway cell toxicity when local P450s are globally inhibited. Funding: R01 ES020867, P30 ES023513 and T32 HL007013

**TP203 PAHs, OCPs and PCBs in sediments from three catchments in Durban, South Africa**

*N. Vogt, R. Pieters, North-West University / Environmental Sciences and Management; B. Newman, CSIR South Africa*

Polycyclic aromatic hydrocarbons (PAHs), organochlorine pesticides (OCPs) and polychlorinated biphenyls (PCBs) are common, and often ubiquitous environmental pollutants. These compounds enter aquatic ecosystems through surface runoff and atmospheric deposition, amongst other sources, where they settle in sediments. Aquatic organisms exposed to these compounds can accumulate these compounds in lipid tissue, with potential toxic effects that include cancers and developmental, immuno-, and reproductive toxicities. In this study, 54 sediment samples were collected from an industrial region in Durban, a busy port city in South Africa. Concentrations of PAHs, PCBs and various OCPs were analysed in the sediment. Their concentrations were compared to sediment quality guidelines to estimate possible risks to sediment-dwelling organisms exposed to these contaminants. Sediment samples were extracted by pressurised liquid extraction and subjected to gel permeation chromatography as a clean-up procedure. Sulphur was removed by treating the sample with activated copper. Further clean-up was conducted using silica gel solid phase extraction. The compounds were quantified using a high resolution gas chromatograph coupled to a mass spectrophotometer. PAHs were ubiquitous, at concentrations between 36–6 800 ng/g dry mass (dm). Congener ratio diagnosis suggests the PAHs were derived predominantly from pyrogenic sources. OCPs and/or their metabolites were detected at varying frequencies and concentrations. The restricted-use OCP dichlorodiphenyltrichloroethane (DDT) and its metabolites were the most often detected OCP and were at a high concentration in sediment at some sites. PCB concentrations varied widely, ranging from below the detection limit to 110 ng/g dm. Comparing these results to international sediment quality guidelines revealed a low risk to sediment-dwelling organisms in most instances. There were, however, exceptions, where a moderate to high risk was estimated depending on compound and guideline used. The mean sediment quality guideline quotient was used to estimate the risk associated with all compounds as opposed to individual compounds. This revealed that these chemicals were present in sediment at 17% of the sites at a concentration likely to present acute toxicity to sediment-dwelling organisms.

**TP204 Polybrominated diphenyl ethers (PBDEs) from three cities in Colombia and their probabilistically risk assessment via breast milk in infants**

*B. Johnson-Restrepo, University of Cartagena / Chemistry and the Environment Group / School of Exact and Natural Sciences; A.C. Torres Moreno, University of Cartagena; L. Puente, K. Mejia-Grau, University of Cartagena / Chemistry and the Environment Group / School of Exact and Natural Sciences; A. Villa, Universidad de Antioquia / Chemical Engineering Department, Faculty of Engineering; O. Rios-Marquez, Universidad de Antioquia; L. Patequiva-Chauta, M. Cobo, Universidad de La Sabana; G. Codling, Masaryk University / RECETOX*

Polybrominated diphenyl ethers (PBDEs) were used as additives in plastics as fire retardants that are ubiquitous in the environment. PBDEs have been detected in human breast milk from several countries. The concentration of PBDEs in breast milk provides not only indication of the body levels in the mother but also allows to determine the potential exposure in neonates. PBDEs and their hydroxylated metabolites are structural similar to thyroid hormones (THs) because they can alter the transport of THs or interact directly with the thyroid gland. There is a rising concern about PBDEs on potential health impact in human due to increasing concentrations in pregnant women can alter the homeostasis of THs during the first three months. Milk samples were collected from Bogota, Medellin, and Cartagena cities in Colombia, Samples (n=60) were analyzed treating them with 20 ml of 0.5 M NaOH solution mixture of ethanol and water (9:1 v/v) at 60°C for 5 h. Organic phase was extracted with 3 ml of hexane and repeated this step 3 times. Extracts were combined and concentrate to 1 ml by a gentle nitrogen stream. Extract was load onto a florisil cartridge and eluted with 10 ml of dichloromethane/hexane (1:3) and finally concentrated to 100 µl prior to Gas Chromatography-tandem mass spectrometry (GC-MS/MS) analysis. Potential risk and its uncertainty were obtained by modeling with Monte Carlo that newborn children have exposure to PBDEs. For each simulation, 25,000 iterations were chosen. The daily intake (DI) of the contaminants (BDE-28, BDE-47, BDE-99, and BDE-153) in breast milk were calculated using the following equation: DI = C x F x I. Where DI is the intake dose (ng contaminant/Kg bw /day), C is the concentration of the contaminant in milk on a lipid basis (ng/g lipid), F is the fat content in milk (g lipid/g milk) and I is the consumption of milk / day). The overall concentration of daily intake PBDE (mean ± SD) was 1.96 ± 2.21 and ranged from 0.325 to 12.14 ng/g- lipid wt. The average dose to infants were 0.013, 0.004, 0.0014, and 0.001 µg/Kg body weight per day, for sum of PBDEs, BDE-47, BDE-99, and BDE-153, respectively. In the risk analysis calculated, hazard quotations for sum of PBDEs do not show a health concern. Acknowledgment: Thanks to Colciencias and Universidad de Cartagena for supporting the project No. 110759634967.

**TP205 Prediction of metal bioaccumulation in fish from a proposed mine discharge**

*J.M. Diamond, M. Bowersox, Tetra Tech, Inc.*

Trophic food web modeling was used to predict metal (copper, zinc, mercury, arsenic, manganese, and nickel) concentrations in fish that people consume and that may be exposed to a proposed submerged mine tailings discharge in a tropical saltwater system. Modeling evaluated the major pathways by which fish could accumulate metals from the proposed discharge. These pathways included benthic organisms, micronekton and zooplankton, forage fish, and bioconcentration from the water column. Site-specific biological, hydrological, and physicochemical information was used to estimate metal exposure concentrations in the water column and sediments and identify aquatic species that could be exposed directly or indirectly to the discharge. Large diurnal vertical movement of plankton and micronekton in the system was an important exposure factor, which was used in conjunction with predicted dispersion plumes of the discharge vertically and horizontally to conservatively estimate exposure concentrations of metals. Results of this study yielded site-specific bioaccumulation and bioconcentration factors of metals for different trophic levels and predicted fish tissue concentrations. Except for mercury, and to a lesser extent arsenic, biomagnification of metals in fish people consume was not predicted, consistent with observed data from different trophic levels at the site. Highest concentrations were observed in micronekton for copper, zinc, and nickel. Zooplankton had the highest concentration for manganese. Trophic transfer factors for fish people consume ranged from 0.01 (nickel) to 0.72 (zinc) based on site data. Trophic tissue data from other active mine sites in the region supported predictions regarding bioaccumulation estimates of metals in fish consumed by people. Based on conservative exposure factors, fish tissue concentrations are predicted to meet food safety standards for all metals except mercury and arsenic. These metals do not consistently meet food safety standards currently (without any mine discharge being present). The proposed discharge is not predicted to increase tissue concentrations for these metals.

**TP206 Risk and Toxicity Assessment of Heavy Metals in Water, Fish and Sediments Samples from Ikun and Ureje Dams in Ekiti State, Nigeria**

*Y. Alli Smith, Ekiti State University, Ado Ekiti / Department of Biochemistry*

Heavy metals have bio-importance as trace elements but the bio toxic effects of many of them in human biochemistry are of great concern. They are natural trace components of the aquatic environment, but their levels have increased due to domestic, industrial, mining and agricultural activities. Due to their toxicity and bioaccumulation, it is important to analyze for different types of heavy metals in our Dams and rivers. This study was carried out to assess the concentration of these metals with a view to evaluate the level of pollution in samples of water, sediment and fish (*Tilapia zillii*) collected from Ikun and Ureje dams in Ekiti State, Nigeria. The results showed that the concentrations of the selected metals are higher in the sediment sample than water sample and the aquatic organism used (*Tilapia zillii*). However, it was observed that Cadmium and Arsenic were absent in the water sample. The values of other parameters present are acceptable in accordance with WHO standards this suggests that the water might be suitable for consumption in form of portable water. The sediment shows that concentration of Iron, Lead, and Cadmium are higher than the WHO standards. This elevated level of heavy metals might contaminate the overlying water which might lead to bioaccumulation by the aquatic organisms present. There is need for constant monitoring because as more industries are established in Ekiti State, Nigeria, the level of heavy metals in these dams may increase progressively. Ikun and Ureje dams in Ekiti State, Nigeria are major sources of pipe borne water for people in the State, therefore checking the level of the metals might minimize the risk of health of the population that depend on the dam for their water and fish supply.

**TP207 Risk Assessment of Chromium and Arsenic Deposition on Soils and Crops at Industrialized locations of South East, Nigeria**

*U. Onyedikachi, Michael Okpara University of Agriculture, Umudike / Biochemistry; C.D. Belonwu, M.O. Wegwu, University of PortHarcourt / Biochemistry*

This study investigated the human health risk associated with Chromium(Cr) and Arsenic(As) through consumption of food crops; vegetables (Pumpkin leaf, Bitter leaf, water leaf) Tubers (yam, cocoyam, cassava), fruits (orange, star apple, pawpaw) and Nuts (coconut, kolanut, palm kernel nut), harvested from selected industrialized areas located in the South Eastern states of Nigeria. The concentrations of As and Cr were determined using Atomic Absorption spectroscopy (AAS). Mean concentrations of Cr exceeded WHO set limit of 0.05 $mgkg^{-1}$ for all study samples ranging from 1.850.21 to 1315.400.57 in Irete(Imo State), 0.350.21 to 58.900.14 in Ngwo(Enugu), 1.100.14 to 196.530.04 in Osisioma(Abia State), 1.500.01 to13150.00 in Akwu – Uru(Anambra State), 4.550.07 to 294.250.35 in Ishiagu(Ebonyi State) and 0.060.00 to 116.200.00 for umudike (Abia State, control Area for this Study) all in Mg/Kg dry weight. There was no statistically marked difference for As in both study and control areas. The order of abundance of Cr in the areas were in the order Akwu-Uru > Ishiagu > Irete >umudike> Osisioma >Ngwo . The highest bioaccumulation index in this study was recorded in *Talinum triangulare*(9.77E+00), *Manihot esculenta* (7.67E+00) and *Dioscorea alata*(7.26E+00) suggesting that they could be tried out as bioindicators in phytoremediation owing to their observed chromium uptake pattern. The daily intake of chromium in the areas of study were above the established reference dose on 0.003Mg/Kg/day recommended by FAO/WHO and USEPA. The Target Hazard Quotient(THQ) of Cr for most of the test samples were >1 indicating that people in the study areas may experience significant health risks from intake of chromium through food crop consumption. The average carcinogenic risk values obtained for Cr and As exceeded the USEPA prescriptions, thus indicating a lifetime (70 years) probability of contracting cancer suggesting that they be placed for further consideration as chemicals of concern with respect to the assessed locals.

**TP208 Risk assessment of heavy metal contamination by multivariate and Hazard Index analyses of a pipeline vandalised area in Nigeria**

*O.O. Ogunlaja, Lead City University / Chemistry; A. Ogunlaja, Redeemers University; O. Morenikeji, University of Ibadan / Zoology; D. Okewole, Redeemers University / Department of Mathematics*

Petroleum contamination is a significant contributor of elevated level of toxic heavy metals, which are of great concern to human health, due to their non-biodegradable nature. Agaye community has experienced frequent gasoline spills due to pipeline vandalisation, resulting in the contamination of soil and water sources. The concentrations of metals (Cd, Cr, Cu, Mn, Ni, Pb, V and Zn) in groundwater, surface-water and soil were determined from a total of 216 samples acquired bi-monthly for two years by Inductively Coupled Plasma-Optical Emission Spectrometry (ICP-OES) to evaluate the impact of oil spills. Multivariate analyses using principal component analysis (PCA) and cluster analysis (CA) were also used to study the interactions between metals and identify the possible sources of contamination. The concentrations of heavy metals in soil and water samples were in decreasing order of Mn > Ni > Zn > Cu > V > Cr > Pb > Cd and Ni > Zn > V > Cu > Mn > Pb > Cr > Cd respectively. Ni concentration ranged from 0.42–8.05 mg $kg^{-1}$ and 0.10-2.85 mg $L^{-1}$ for soil and groundwater respectively. Ni and V were more enhanced ($p < 0.05$) in soil samples. This study showed that there is a significant relationship between elevated levels of Cr, Cu, Ni and Zn and oil spillage, due to petroleum spills and that residents are vulnerable to and at greater risk of non-carcinogenic hazards if they consumed groundwater. Multivariate analyses showed significant anthropogenic intrusions of two diagnostic heavy metals (Ni and V) for petroleum contamination in the soils and water sources.

**TP209 Screening ecological risk assessments of polymers used in cleaning products: Polyquaternium 6 and Polyquaternium 10**

*M. Lam, The Procter & Gamble Company / Global Product Stewardship; K. Stanton, D. Ferrer, American Cleaning Institute; A. Carrao, Kao USA / R&D*

Polymers are important ingredients in everyday products including cleaning products. The American Cleaning Institute (ACI) recently sponsored an industry-wide survey of polymers used in down-the-drain cleaning products in the United States whose results were used to identify polymer classes for further investigation based on hazard categorization, data availability, and prioritization for ecological risk assessment. Of these polymers, the class of Polyquaterniums were identified for further study, and within this class, Polyquaternium 6 (PQ6; CAS 26062-79-3) and Polyquaternium 10 (PQ10; CAS 68610-92-4) were selected as case studies for screening level ecological risk assessments using the publicly available data identified from the survey. PQ6 and PQ10 have diverse properties and functions as they are used in cleaning products, in addition to other industrial and consumer applications. While privately held data exist, and were likely used along with publicly available data for internal assessments by cleaning product companies, this assessment is limited to publicly available fate and effects data for PQ6 and for PQ10 variants of molecular weight and charge density. The databases searched in Phase 1 of this ACI project were previously discussed and include (but are not limited to) *Scopus*, *Web of Science*, *Environment Complete* and *Toxline* (including *PubMed*), USEPA ECOTOX (2017), the ECHA Information on Chemicals (2018), the Human and Environmental Risk Assessment (HERA) on ingredients of household cleaning products (2018), and the USEPA Safer Choice Chemical Ingredient List (2018). Several acute and chronic aquatic toxicity data are available for a form of PQ6 used in water treatment (Magnafloc 368). Acute EC/LC50s for PQ6 range from 0.03-0.075 mg/L, and chronic endpoints range from 0.0042 – 0.500 mg/L. The data are limited for PQ10 environmental fate and effects. Only acute aquatic effects data are available, with EC50s for PQ10 ranging from 0.4- 1.2 mg/L. Low to moderate wastewater treatment plant (WWTP) removals for PQ6 and PQ10 are estimated ranging from 13-38%. The fate and effects data for PQ6 and PQ10 were reviewed and evaluated for robustness for use in screening level risk assessments. Preliminary findings and recommendations for next steps to refine and improve the risk assessment are shared. Limitations with using the current limited data set for screening assessments are also discussed.

**TP210 The US Forest Service Worksheet Tool: An evaluation of its application in modern risk assessment and methods for maintaining contemporary relevance**

*K. Phang, D. Bonnar, Blankinship & Associates, Inc.*

The U.S. Forest Service Risk Assessment Worksheet Tool (FSWT) is a highly sophisticated Microsoft Suite based application developed to assist in performing risk evaluations. This highly accessible tool uses a macro-enabled Word processor, Excel spreadsheet, and Access database to guide a user through the risk assessment process, and generate risk values from toxicity data, chemical properties, water and off-site soil contamination rates, and built-in exposure assumptions. Risk assessors are presented with the challenge of adapting tools and models to new risk assessment methodologies as methods are updated. Computational tools such as the FSWT can be adapted to accommodate these refinements to risk assessment methodologies. This analysis will highlight the advantages and limitations of the FSWT, and demonstrate strategies to adapt the tool to accommodate updates to exposure assessment methodologies.

**TP211 Profiling of Environmental Contaminants using GC/Q-TOF**

*S. Nieto, Agilent Technologies, Inc; K. Chen, Agilent Technologies, Inc / Workflow Solutions; P. Wylie, Agilent Technologies, Inc. / Market Development; T.M. Young, University of California, Davis / Civil and Environmental Engineering*

The investigation of organic micropollutants is an important aspect of assessing environmental quality. The conventional approach to this monitoring involves analyzing a defined number of target compounds by mass spectrometry with the instrument operated in a selected data acquisition mode for targeted analytes. However, there is evidence that such an approach may significantly underestimate the exposure and risk of pollutants, compared to a more comprehensive untargeted screen. Recent advances in mass spectrometry allows an increased scope of analysis, no longer sensitivity or selectivity limited when using high resolution accurate mass instruments operated in full spectrum acquisition mode. Accurate mass information enhances the amount of detail in the information collected and allows for the determination of both targeted and non-targeted components. One of the challenges that this information rich data can present is determining what samples warrant a more detailed investigation. This work will present some of the workflow possibilities for profiling of samples to quickly identify samples of interest, potential targets for further compound identification. Retrospective targeted data mining also becomes possible for researchers when an emerging contaminant is discovered, further increasing the importance of this data when determining the cause of environmental events. Finally, the use of new instrument capabilities such as Low Energy EI, and expanded retention time and accurate libraries will be demonstrated for compound ID.

## Aquatic Toxicology, Ecology and Stress Response – Part 1

**TP212 A comparative study of the toxicity of the insecticide fipronil to aquatic neotropical species**

*R.A. Moreira, Escola de Engenharia de São Carlos / Universidade de São Paulo USP / SHS Departamento de Hidráulica e Saneamento; J. Freitas, T. Junio da Silva Pinto, Universidade de Sao Paulo / Hidraulica e Saneamento; L. Conceição Menezes da Silva, Universidade de Sao Paulo / Núcleo de Ecotoxicologia e Estudos Ambientais; M. Daam, CENSE & New University of Lisbon, Lisboa; L.C. Schiesari, University of São Paulo / Escola de Arte, Ciências e Humanidade; E. Espindola, University of São Paulo / Hydraulics and Sanitation*

Sugarcane cultivation has been highlighted in the Brazilian landscape with excessive application of insecticide fipronil. The aim of the present study was to evaluate the toxicity of Regent® 800 WG (a.i. fipronil) using a test battery of organisms that are native species with common occurrence in Brazilian freshwaters: Cladocera (*Ceriodaphnia silvestrii*), Oligochaeta (*Allonais inaequalis*), Diptera (*Chironomus sancticaroli*), Amphipoda (*Hyalella meinerti* and *Strandesia trispinosa*) and Amphibia (*Leptodactylus fuscus* and *Physalaemus nattereri*). All experiments were carried out under controlled temperature (25±1°C) and photoperiod (12h light:12h dark) and performed in triplicate. The test with *C. sancticaroli* was made with 240 mL test solution, 60 g artificial sediment and six organisms. For *H. meinerti*, 100 mL test solution was used with five organisms. Both tests lasted 96h. For *S. trispinosa* and *A. inaequalis*, the bioassays were carried in 10 mL test solution, with five organisms for 48h (*S. trispinosa*) and six organisms for 96h (*A. inaequalis*). For tadpoles, contained 5L test solution and five organisms for 96h. For cladocerans, consisted in five neonates for 96h. Species sensitivity distributions (SSD) were constructed to compare the acute EC50 values derived for the native species and other invertebrate and fish species. By means of the SSD, we observed that the species *Chironomus dilutes* is the most sensitive (0.03 µg/L), followed by *Americamysis bahia* (0.14 µg/L) and the *Cheumatopsyche brevilineata* (0.15 µg/L). With respect to native species, *H. meinerti* (1.29 µg/L) showed the greatest sensitivity, followed by *C.*

*sancticaroli* (6.19 µg/L), *C. silvestrii* (9.7 µg/L) and *S. trispinosa* (53.24 µg/L). For *A. inaequalis, L. fuscus,* and *P. nattereri*, no effects were noted on the survival even at the highest concentration tested 100 mg /L for the oligochaetes and 800 mg/L for the tadpoles. Therefore, these species were the least sensitive to fipronil, being more resistant than the fish *Danio rerio* (181 µg/L) and *Oncorhynchus mykiss* (246 µg/L). Studies in Brazil recorded concentrations of 0.1 to 26.2 µg/L of fipronil in rivers in the state of Rio Grande do Sul and 4.23 µg/g in sediment of marginal lagoon of the river Mogi-SP. Based on these records, *H. meinerti* and *C. sancticaroli* would be at risk at such an exposure scenario. The present study demonstrated that toxic effects on tropical species are likely to occur at environmentally realistic exposure levels.

**TP213 A Look at Bacteria, Metals, and Polycyclic Aromatic Hydrocarbons in Reach 3 of the Los Angeles River**

*M. de Orla-Barile, California State Univ, Long Beach / Electrical Engineering; S. Appleton, Los Angeles River Kayak Safari; V. Lorenzi, California State University, Long Beach / IIRMES; E.B. Holland, California State University, Long Beach / Biological Sciences*

The Los Angeles River (LAR) watershed receives wastewater and runoff from a variety of inputs including stormwater runoff from nearby roadways and industrial/residential areas. The historic and on-going pollution that flows into the LAR has led to its listing on the U.S. Environmental Protection Agency's (EPA) 303d listing of impaired waterbodies. There are currently numerous efforts underway to increase water quality in the LAR in order to support public access to the urban watershed while protecting human health. The current study aimed to identify storm drains that may be contributing to the pollutant load in the LAR by acting as ongoing contaminant sources. Focusing on Reach 3 of the LAR, an area with active recreation, storm drains on the east and west side of the river were selected as a concern if they were observed to experience on-going and daily persistent water flow into the river. For each identified storm drain, water was sampled in April, 2017 (n = 6) and July, 2017 (n = 5) and assessed for bacteria, total and dissolved trace metals, and polycyclic aromatic hydrocarbons (PAH's). Bacteria loads at the different sites often exceeded recreational standards by the greatest representing the most prominent contaminant of concern in the storm drains. Several samples had PAH's, such as Chrysene, Benz[a]Anthracene, and Benzo[a] Pyrene among others, in concentrations that exceeded other regulatory limits. Metals tested for did not exceed the regulatory threshold used for comparison. These sampled sites represent a continual source of contamination to the LAR and future work should be focused on testing the application of best management practices (BMP's) that could alleviate these water quality concerns.

**TP214 A model to estimate photo-enhanced toxicity of petrogenic PAHs to aquatic organisms in Canadian Boreal Lakes**

*J. Dearnley, University of Manitoba / Chemistry; S. Havens, IISD Experimental Lakes Area / Chemistry; S. Higgins, V. Palace, IISD Experimental Lakes Area; M.G. Barron, USEPA / Gulf Ecology Division; G. Tomy, University of Manitoba / Department of Chemistry*

The boreal shield is Canada's largest terrestrial ecozone covering more than 1.8 million km$^2$ and containing more than 22% of the country's freshwater resources. While numerous crude oil pipelines cross the boreal zone, additional information is required regarding the fate and behaviour of spilled oil, and its potential to induce toxicity to resident aquatic organisms. In terms of chronic toxicity, polycyclic aromatic hydrocarbons (PAHs) represent the most toxicologically relevant compounds in crude oil. Current understanding of PAH toxicity includes recognition that exposure to UV radiation can potentiate the toxicity of these compounds by up to 100 fold, but models applicable to clear, oligotrophic lakes in the boreal zone are not available. We present a model that describes the potential for enhanced PAH toxicity to freshwater organisms exposed to two commonly transported crude oils (diluted bitumen and conventional heavy crude). The model accounts for ranges of UVA and UVB exposures in lakes with varying dissolved organic carbon (DOC) content, standing phytopklankton biomass and total suspended solids. Coupled with summaries of historic spill volumes, this model specifically addressed the potential for photo-enhanced toxicity of PAHs to different life stages of model freshwater organisms in the boreal shield region.

**TP215 A sulphate and total dissolved solids (TDS) toxicity interaction study for coal mine influenced waters in British Columbia**

*J.L. Van Geest, G. Lawrence, Golder Associates, Ltd.; J. Elphick, Nautilus Environmental; A. deBruyn, Golder Associates, Ltd. / Environmental Science*

The toxicity of sulphate to many freshwater organisms decreases with increasing water hardness, which is accounted for in a hardness-dependent British Columbia water quality guideline (BC WQG) for sulphate. However, the BC WQG recommends site-specific evaluation for very high hardness conditions due to uncertainty regarding cumulative effects of component ions in the mixture. Hardness in mine-influenced receiving waters of many coal mines in BC is currently or is predicted to increase to very high hardness. We conducted a sulphate and total dissolved solids (TDS) interaction study to address these uncertainties. The overall objective was evaluate whether sulphate, along with related ions in a site-relevant mixture, is of potential concern with respect to toxicity in mine-influenced waters under current and modelled future conditions. A related objective was to assess how the toxicity of sulphate is expected to change as modifying factors such as TDS and hardness increase over time based on predictions of future operations. Site-specific, chronic toxicity tests were conducted following standardized laboratory protocols using *Ceriodaphnia dubia*, *Hyalella azteca*, *Centroptilum trangulifer*,and rainbow trout (*Oncorhynchus mykiss*). Mine-affected water samples were spiked with a series of sulphate concentrations added as calcium and magnesium salts in an ion ratio consistent with site waters. The range of tested sulphate concentrations encompassed current site conditions, predicted increases under future conditions, and concentrations anticipated to yield significant effects. A 25% effect on *H. azteca* growth (560 mg/L) and *C. triangulifer* emergence (840 mg/L) were observed in one test water, whereas effects concentrations were higher in the other test water. Apart from these results, the invertebrate species exhibited no effects on survival and sublethal endpoints at sulphate concentrations up to 1,400 mg/L. Rainbow trout exhibited variable responses, but on average showed no effects on embryo-alevin survival and development at sulphate concentrations up to 1,100 mg/L. For all four species, increasing hardness and associated concentrations of major ions did not appear to increase sulphate toxicity under the conditions tested. This study demonstrated that testing of site-relevant ion mixtures (i.e., calcium and magnesium increasing with sulphate) is more relevant to coal mines than the sodium-sulphate toxicity testing upon which the BC WQG for sulphate is based.

**TP216 A synthesis of mercury and selenium concentrations in freshwater fishes in the Western United States**

*A.R. Stewart, USGS / National Research Program Western Branch; J.T. Ackerman, USGS / Western Ecological Research Center; C. Eagles-Smith, USGS / Forest and Rangeland Ecosystem Science Center*

Mercury (Hg) and selenium (Se) have the potential to threaten wildlife and impede ecosystems restoration efforts across a range of terrestrial and aquatic habitats. Hg has a strong binding affinity for Se that could potentially reduce Hg bioavailability, bioaccumulation, and ultimately toxicity, yet the implications of these interactions for mercury monitoring and policies remain unclear. We evaluated paired Hg-Se concentrations for 8,657 freshwater fishes in the Western United States, that represent a range of exposure gradients, tissues, species and habitats. Hg and Se were negatively correlated in linear space, but this pattern is common for many trace elements in the environment because trace element distributions are generally log-normally distributed (right skewed). Therefore, another approach is necessary to interpret Hg-Se patterns. Hence, we constructed statistical models to determine the predominant drivers of Hg concentrations and founds that Se explained only a small proportion (97.5% of samples (as found in previous smaller scale surveys), suggesting that finding a freshwater fish in the Western US with insufficient Se to (supposedly) protect against Hg toxicity would be exceedingly rare. We conclude that a protective role of Se against Hg bioaccumulation is not detectable in freshwater fishes in the Western United States based on their co-occurrence in the environment. Interactions between Se and Hg are complex, dynamic, and their role in Hg or Se toxicity require studies that focus on understanding specific mechanisms and take into consideration ecologically relevant exposure concentrations, chemical species, and toxicological effects.

**TP217 Acute toxicity of ionic liquids with differing chemical structures to *Daphnia magna***

*S.M. Weir, B. Leger, Queens University of Charlotte / Biology; C. Kong, MD Anderson Cancer Center; A. Socha, Queens University of Charlotte*

Ionic liquids (ILs) are an emerging chemical class of importance to industrial activities and biofuel production. Ionic liquids are ionic compounds that are liquid at room temperature. As interest increases to create more sustainable biofuels, much research has been performed to understand the use of ILs to decrease the use of toxic solvents. ILs with methoxylated cations can be prepared from renewable resources (e.g., lignin-derived vanillin) rather than petroleum derivatives that are common for other ILs, which have implications for sustainability. However, as production of ILs increases, it is important to quantify toxicity of these ionic compounds to ensure minimal risk to environmental organisms in the case of a chemical spill or from industrial waste. At the same time, for industrial purposes it would be important to identify the most efficient ILs that are also the most environmentally benign. We present here an investigation into the acute toxicity (48 hour LC50s) of different ILs to *Daphnia magna* in relation to chemical structure of the cation and anion. We investigated four ILs: benzyltrimethyl ammonium hydroxide, benzyltrimethyl ammonium methylsulfonate, dimethoxybenzyltrimethyl ammonium methylsulfonate, trimethoxybenzyltrimethyl ammonium methylsulfonate. We hypothesized that toxicity would decrease with decreasing lipophilicity/increasing polarity of the cation constituent of the IL (in this case, more methoxy groups would be less toxic). The LC50s of all four ILs were greater than 22 mg/L. The most toxic IL was benzyltrimethyl ammonium methylsulfonate (LC50 ± 95% CI = 22.8 mg/L ± 5.0) and it was significantly more toxic than the same cation paired with a hydroxide ion (LC50 ± 95% CI = 97.4 mg/L ± 9.7). Adding methoxy groups to the benzene ring generally decreased toxicity with 2 methoxy groups being the least toxic (LC50 ± 95% CI = 121.3 mg/L ± 31.6) and trimethoxy being intermediate in toxicity (LC50 ± 95% CI = 41.2 mg/L ± 2.4). Our hypothesis was partially supported in that adding methoxy groups decreased toxicity, but not in a linear relationship with increasing methoxy groups. Changing the anion also significantly altered toxicity which was an unexpected result though hydroxide is expected to be a fairly non-toxic anion. Chronic studies should be conducted on those ILs that are deemed of greatest industrial potential to ensure that low levels of ionic liquids released into the environment will not harm aquatic organisms.

**TP218 Acute toxicity of thiocyanate and cyanate to rainbow trout across a range of conditions**

*J.L. Van Geest, L. Ashby, Golder Associates, Ltd.; A. deBruyn, Golder Associates, Ltd. / Environmental Science; J. Elphick, Nautilus Environmental*

Acute toxicity to rainbow trout (*Oncorhynchus mykiss*) was observed in effluent associated with cyanide detoxification and acid rock drainage discharges from a gold mine in South America. A review of effluent chemistry indicated that effluent concentrations of nitrogenous compounds (ammonia, thiocyanates, and cyanates) sometimes exceeded published LC50s for rainbow trout. While the toxicity of ammonia and associated exposure and toxicity modifying factors (ETMFs) is well characterized, more limited data exist to characterize the toxicity and ETMF relationships for thiocyanates and cyanates. To address these data gaps, we conducted a laboratory toxicity study of the acute toxicity of thiocyanates and cyanates to rainbow trout across a site-relevant range of temperature, pH, and hardness. Relationships between toxicity and ETMF conditions were evaluated and described with regression analysis. There was no significant effect of temperature, pH, or hardness on thiocyanate toxicity under the conditions tested. Temperature and pH effects were inconsistent and generally small, while the effect of hardness was not monotonic. Cyanate toxicity could not be characterized at low pH of 6.0 due to rapid degradation of the compound under these conditions, which precluded characterization of pH effects in this study. At higher pH of 8.5, where cyanate concentrations were stable, there was no significant effect of temperature or hardness on cyanate toxicity.

**TP219 Adaptation of Leptocheirus plumulosus bioassay to measure bioavailability and bioaccumulation of methylmercury in an oligohaline estuarine environment**

*D. Farrar, USACE ERDC / Enviromental Laboratory; S.B. Kane Driscoll, Exponent, Inc. / EcoSciences; C. Gilmour, Smithsonian Environmental Research Center; S.S. Brown, The Dow Chemical Company / Environmental Remediation and Restoration*

A bioaccumulation bioassay was developed using the marine/estuarine amphipod *Leptocheirus plumulosus* to assess the effects of fresh and field-aged activated carbon (AC) amendments on the bioavailability and biouptake of methylmercury. The study was performed using highly organic sediments collected from a tidally-influenced oligohaline marsh (~5 ppth salinity) dominated by *Phragmites*. Challenges specifically associated with evaluating methylmercury biouptake in a low-salinity environment required an iterative approach to test method development (trial and error). *Leptocheirus plumulosus* is a surface-deposit feeding benthic invertebrate that tolerates a relatively wide salinity range, and so it is ideal for evaluating biouptake from sediments in a salinity-challenged system. Adverse test conditions encountered in early testing demonstrated the need to carefully monitor redox, pH, DO, etc. and to establish geochemical equilibrium in the test chambers prior to initiating the bioaccumulation phase of the test. So, sediments and water were allowed to equilibrate in test chambers for 7 days prior to adding test organisms, and overlying water quality (pH, oxygen, salinity, ammonia), porewater parameters (metals, carbon, anions, pH and ammonia), redox (Eh), and porewater methylmercury concentrations were monitored during this period. During the 7-day equilibration period, pH and ammonia declined to acceptable levels, and redox stabilized, and sufficient methylmercury was produced. After equilibration, pre-acclimated amphipods were placed in test chambers to initiate a 21-day bioaccumulation phase. Overlying water quality, porewater parameters, redox, and porewater methylmercury levels were monitored on days 7, 14, and 21, and amphipods were retrieved at each 7-day interval to assess methylmercury bioaccumulation. *Leptocheirus* survival and growth was excellent for the duration of the study (in lab controls, field controls, and treatments) and sufficient biomass was available for measuring methylmercury uptake. Challenges encountered and additional modifications to the published *Leptocheirus plumulosus* test method will be discussed and a final test design will be presented.

**TP220 Adjusting Arsenic Aquatic Life Criteria: Toxicity Updates, Arsenic Species, and Species Sensitivities**

*L.B. Martello, P.C. Fuchsman, L. Brown, M.T. Sorensen, Ramboll*

A model has been developed to recalculate fresh and saltwater arsenic water quality criteria using recent toxicological data for arsenic and the specific toxicities of the different species of arsenic typically present within a water sample. The current National Recommended Water Quality Criteria (NRWQC) for arsenic in fresh and saltwater reported in USEPA (1984) and adopted by several state agencies is based on data that is more than 30 years old. A considerable amount of new toxicological data for arsenic is available since the value was initially developed. Additionally, the current recommended water quality criterion for arsenic was derived from data for trivalent arsenic (arsenite; $As^{3+}$), the most toxic of the arsenic species, but is applied to total arsenic. A reevaluation of the NRWQC is provided here that uses recent arsenic toxicity data available from the literature versus the limited dataset from 1984 used in the derivation of the current arsenic NRWQC. Notably, this review supports an alternative, lower acute-chronic ratio. The approach then considers the contribution and toxicities of different arsenic species rather than assuming that As3+ makes up 100% of the water sample at a site. Other arsenic species considered in this recalculation are: inorganic pentavalent arsenic (arsenate or As5+), organic arsenite (org As3+), and organic arsenate (org As5+). Toxicity ratios were developed by comparing As3+ to the other arsenic species. These toxicity ratios were then applied to the adjusted As3+ criterion based on the most recent toxicity data to determine an adjusted water quality criterion for each arsenic species. A weighted average criterion value can then be calculated by multiplying the adjusted water quality criterion by the proportion of each arsenic species averaged across a site. For application to sediment porewater data, an additional adjustment involved evaluating the relative sensitivity of infaunal versus epibenthic and pelagic species to arsenic. These tools are expected to improve the realism of arsenic risk estimates for contaminated sediment sites.

**TP222 An evaluation of two synthetic culture waters dosed with vitamins, selenium, or a combination of the two for optimal culturing of Ceriodaphnia dubia**

*M.D. Brown, Sanitation Districts of Los Angeles County / Biology Group; L. O'Donahue, Los Angeles County Sanitation Districts / San Jose Creek Biology; C.M. Barton, Sanitation Districts of Los Angeles County / Biology Group; S.S. Thompson, Sanitation Districts of Los Angeles County; J. Linnenbrink*

Culturing live organisms for toxicity testing requires optimization of a multitude of variables to maintain healthy organisms over time. Many of these variables center around the quality and chemical composition of the water used to culture the organisms. *Ceriodaphnia dubia* (*C. dubia*) is a sensitive species that can be difficult to maintain in the laboratory. This study was performed in efforts to determine if commonly used culture waters, amended with different supplements that have been previously reported as beneficial, could improve the long-term health of *C. dubia* in our laboratory. This study focused on the effect of two different culture waters containing a vitamin mixture (*i.e.*, biotin, thiamine, and vitamin $B_{12}$) and/or selenium on the health and stability of *C. dubia* cultures. Separate cultures were maintained for 32 weeks using moderately hard mineral water or reconstituted hard water. A series of experiments were performed using the two culture waters with one of the following four manipulations: (1) no manipulation, (2) vitamin addition, (3) selenium addition, and (4) vitamin plus selenium addition, for a total of eight different culture water types. Using survival and reproduction endpoints to assess *C. dubia* health, it was determined that there were no statistically significant differences between seven of the eight manipulations. The only manipulation that demonstrated statistical significance was the reconstituted hard water with selenium which was terminated after 12 weeks due to low reproduction and poor survival. The reproduction in the remaining treatments averaged 32-34 neonates per female in the first three broods and the mean survival of all treatments was >93%. Adding supplements to the two culture waters did not prove to enhance the health of the organisms and only the reconstituted hard water with selenium appeared to have a negative impact on *C. dubia* health. Both un-manipulated culture waters were successful in maintaining healthy *C. dubia* cultures during this study.

**TP223 Analysis of Harmful Algal Blooms in Central Tennessee**

*F.C. Bailey, Middle Tennessee State University / Department of Biology; T. Ribiero, Tennessee State University; A. Todd, J. Jatko, Middle Tennessee State University / Biology; T. Byl, Tennessee State University*

Harmful algal blooms (HAB's) are destructive hydrological phenomena caused by rapid reproduction of cyanobacteria. These cyanobacteria can potentially release numerous malicious cyanotoxins, such as microcystin and saxitoxin into the water during a HAB event. HAB cyanobacteria grow at alarming rates that can asphyxiate a water body and be harmful to the aquatic life in the surrounding area, as well as pose a threat to any human drinking-water intake facilities located there. The number of HAB's has increased dramatically worldwide in the past few decades and has been linked to the growing number of water bodies experiencing anthropogenic eutrophication and increasing global temperature. According to the Tennessee Department of Environment and Conservation (TDEC), 32 water bodies in Tennessee are susceptible to HAB's based on their water quality history. However, little data exists on HAB's prevalence in Tennessee water bodies, although low levels of microcystin have been found at several agricultural and drinking water intakes around the state. The objective of this study is to seasonally quantify toxin-producing HAB species (e.g. *Microsystis spp* and *Anabaena spp*) as well as toxins that are present at a central Tennessee agriculture-influenced wetland and two drinking water intakes. Water parameters, including temperature, dissolved oxygen, phosphorus and nitrogen levels will be collected at the time of sampling. Toxins will be extracted using a SPE extraction protocol and analyzed via LC/MS. Toxin producing organisms as well as toxin genes present will be identified and quantified using qPCR. Several cyanobacteria genera capable of producing cyanotoxin were found to be present in the wetland during initial summer sampling, including Dolichospermum, Chrysosporum, Aphanizomenon, Anabaena, Oscillatoria, Pseudoanabaena, and Lyngba as well as low levels of microcystin and saxitoxin. The microcystin concentrations ranged from below detection to 0.26 µg/L. The saxitoxin concentrations ranged from below detection to 0.07 µg/L. The peak microcystin concentrations were just below the USEPA's health advisory concentration. Correlations of toxin and organism levels with water quality parameters will also be done. These data show potential risk from cyanotoxins in Tennessee water bodies.

**TP224 Assessing Environmental Surface Water Exposure by Cell Culture-based Metabolomics**

*Y. Yue, J.D. Mosley, USEPA / National Exposure Research Laboratory; P.M. Bradley, USGS / South Atlantic Water Science Center; J.E. Cavallin, Badger Technical Services / National Health and Environmental Effects Research Laboratory; D.L. Villeneuve, G.T. Ankley, USEPA / National Health and Environmental Effects Research Laboratory; D. Ekman, T. Collette, Q. Teng, USEPA / National Exposure Research Laboratory*

The presence of anthropogenic contaminants in environmental surface waters often results in potential health risks for humans and wildlife. As promising approaches, 'omics techniques have been developed to assess environmental risk and evaluate potential toxic impacts of chemical contaminants. Metabolomics is the 'omics approach to understanding cell and system level biology, and has been applied in vitro for monitoring biological impacts of water contaminants and aquatic environmental stressors. Combined with high-resolution liquid chromatograph mass spectrometry (HR LC-MS), metabolomics can investigate endogenous metabolites of organisms and cells, and their significant variations under chemical exposure for discovering potential biomarkers, elucidating metabolic pathway alternations, and assessing biological impacts of chemical exposure. In this study, we applied cell culture-based metabolomics to investigate impacted biological pathways by chemical contaminants in surface water samples collected from 8 stream sites. These 8 sites were selected from 38 stream sites collected nationwide with different land occupations and chemical contaminated status, based on the number of detected chemicals in the surface water samples. Two human cell lines (liver cell, HepG2 and brain cell, LN229) and one fish cell line (zebrafish liver cell, ZFL) were exposed to these surface water samples for 48 hr. HR LC-MS was applied to investigate the impacts of chemical contaminants on endogenous polar metabolomes and biological pathways of the cells. The results provide insights into the ecological impacts of environmental contaminants on water ecology risk through a molecular-based evaluation.

**TP225 Assessing sedimentation of the Upper Cache River Watershed, Arkansas through proxy measurements**

*A.K. Atwell, J. Bouldin, Arkansas State University / Ecotoxicology Research Facility*

Nearly 50% of all assessed streams in the United States are impaired for not meeting their designated use. The leading cause of impairment is non-point source pollution from agricultural land use. One common practice of streams draining agricultural lands is channelization. Channelization, a form of channel alteration, involves making stream channels deeper and wider to increase the hydraulic loading during flood events. This process can lead to increased stream sedimentation, reduced stream water quality, negatively impacted aquatic biota, and potentially lead to stream impairment. In the Cache River Watershed, located in northeast Arkansas, approximately 70% of the 230-km-long watershed is used for agricultural purposes. Nearly 150 river-kilometers are channelized and over 200 river-km are listed as impaired for not supporting aquatic life with sedimentation from agriculture as the leading cause. The goal of the project is to monitor sediment contributions and water quality of the Cache River Watershed through proxy measurements. Turbidity and total suspended solids (TSS) have been analyzed weekly since October 2017, in 13 spatially independent tributaries in the Upper Cache River Watershed. Preliminary results indicate there is a significant association between TSS and agricultural land use within the subwatershed and, when grouped into levels of agricultural intensity, there is a significant difference in turbidity between low agricultural intensity and subwatersheds classified as moderate or high intensity. In this present study, subwatersheds with moderate and high levels of agricultural intensity exceed the Arkansas Department of Environmental Quality's turbidity limit for channel-altered delta streams ≥25% of the time. These results suggest that the intensity of agricultural activities play an important role in the amount of sedimentation of the Cache River Watershed, which may also be contributing to sediment levels in the Mississippi River and ultimately into the Gulf of Mexico.

**TP226 Assessment of bioaccumulation potential of very hydrophobic compounds in Rainbow Trout and the role of metabolism**

*M. Cantu, Simon Fraser University / Resource and Environmental Management*

Given the wide use of hydrophobic siloxane compounds, more care is being taken by legislators around to globe to regulate any potential bioaccumulative and toxic substances in the environment. Likewise, the abundance of the global production of siloxanes demonstrates the importance of these bioaccumulation studies and how best to aid in the addition of the knowledge of how these compounds interact in the environment. Also, with the current guidelines set by government bodies, only one chemical is tested at a time. The present proposal aims to help prove the importance of chemical mixture studies in the hopes of showing the complex nature of a cocktail of chemicals within the environment and any given organism that comes in to contact with said chemicals. The main objective of this study has been to determine in-vivo and in-vitro biotransformation rates of various siloxanes in fish. Concentration-dependent biotransformation will be assessed by reviewing the depuration rate constant over time at varying concentrations to determine if $K_T$ is dependent on the concentration of siloxanes within the organism. Preliminary results have shown varying results between the cyclic and linear siloxanes. Specific plans for these studies are as follows: (1) run individual siloxane exposures to juvenile rainbow trout fish (D4, D5, D6, L3, L4, L5) at a concentration of 4.5mM siloxane/g food for and update duration lasting 21 days. Since the depuration rates for the cyclical siloxanes are very slow, and through previous work done in our lab, this high concentration should suffice to represent a depuration rate value, this will also save time and cost for the project. Also, the depuration phase will be extended out further than that of the linear siloxanes. (2) After analysis of linear samples have been completed, subsequent studies will be run at lower and varying concentration to determine if depletion rates are concentration-dependent. (3) The final in-vivo experiment will be run as a mixture of all 6 siloxane compounds at various concentrations to determine if the presence of multiple compounds will alter the depletion rate of other compounds. Test chemicals for both in-vivo studies include: D4, D5, D6, L3, L4, L5, labeled 13C-L3/L4/L5, 13C-D4,D5,D6 for internal standards, reference chemicals used will include: 1,3,5-trichlorobenzene, 1,2,4,5-tetrachlorobenzene, pentachlorobenzene, hexachlorobenzene, PCB 52, PCB 153, and PCB 209 with pyrene used as an external standard.

**TP227 Cigarette butt litter: A threat hiding in marine sediment**

*V. Lorenzi, California State University, Long Beach / IIRMES; I. King, California State University, Dominguez Hills; M. Blasius, R. Gossett, California State University, Long Beach / IIRMES*

Smoked cigarettes get discarded daily on the ground and eventually get transported to aquatic environments by storm water runoff, making cigarette butts a common sight during beach clean-ups worldwide. While the toxicity of many cigarette and tobacco constituents is well known, information is lacking on the impact of cigarette waste on marine sediment. In the current study, cigarette butts were buried into marine sediments in tanks containing seawater, and the exposed sediment was sampled periodically over 60 days. Our aim was to identify toxic chemicals that can leach out from smoked cigarettes and persist in sediment causing a potential negative effect on aquatic organisms. In addition, we aimed to identify some chemical candidates to use as markers of cigarette pollution. Cigarette butts and exposed sediment were solvent extracted and analyzed via gas chromatography/mass spectrometry (GC/MS). Chemicals extracted from sediment were compared to those extracted from cigarette butts to identify compounds present in both. Some tobacco alkaloids and its derivatives (nicotine, cotinine, myosmine, and β-nicotyrine) were the prevalent cigarette constituents being detected at every sampling point. Many linear alkanes were also identified both in cigarette butts and sediment but since they are a common pollutant due to oil spills and boat traffic, the pyridine derivatives were considered the best markers of cigarette pollution within aquatic sediments. Our results suggest that cigarette waste could potentially have both acute and chronic effects on sediment infauna since these toxic chemicals do not just leach out and quickly dilute in the water column but they associate to the sediment for an extended period of time.

**TP228 Consideration of species selection and endpoint design in the construction of Species Sensitivity Distributions**

*M.J. Bradley, Smithers Viscient / Ecotoxicology*

The risk of plant protection products (PPP) to aquatic organisms in Europe can be evaluated through a three tier process. Tier I testing evaluates risk to a small number of standard guideline species, and conservative assessment factors are applied to determine the regulatory acceptable concentration (RAC). If predicted environmental concentrations exceed the RAC, the evaluation of risk must be refined, or use patterns of the PPP must be modified to reduce risk. Tier II testing provides the option of refining risk based on additional laboratory testing, while Tier III testing evaluates risk based on model ecosystem testing. Tier III provides the greatest opportunity for refinement, however, these experiments are quite labor and data intensive, and interpretation may be subjective. Tier II testing largely revolves around standardized testing with potentially non-standard species to better understand taxonomic risk. A species sensitivity distribution (SSD) provides the opportunity to reduce Tier I safety factors from 100 to as little as 3, but its utility depends on the relevance and reliability of the test data collected. In terms of relevance, the test species must be reasonably sensitive and taxonomically germane. In terms of reliability, the derived endpoint(s) must be robust, structured, and should be criteria driven. When considering non-standard species, the direct applicability of an established guideline or test method is unlikely, so how does one evaluate the right candidates for construction of an SSD? This presentation will review the necessary considerations when developing an SSD based on testing experiences and industry response. Logistic concepts such as species selection, endpoint selection, test design and reasonable feasibility will be evaluated, as well as regulatory concerns and opinions of the final product that must be considered as part of the overall design.

**TP229 Determining the no observed effect concentration of atrazine to zooplankton for use in metacommunity studies**

*R. Bowser, A. Dzialowksi, J.B. Belden, Oklahoma State University / Integrative Biology*

The effects of pesticides on aquatic ecosystems are most frequently studied in the framework of single species effects or under the assumption that local communities are isolated. Using metacommunity theory, biodiversity dynamics and spatial patterns of species distributions and abundances can be explained through dispersal and linkages between different spatial scales. The broader objective of this research is to understand how metacommunity dynamics affect zooplankton community responses to stressors that directly affect their resource base (phytoplankton). Before conducting metacommunity studies, however, individual sensitivity tests to the chemical atrazine were conducted to determine the concentration of atrazine that has no or limited direct effects on several species of zooplankton, yet inhibits the growth of green algae. Several species of zooplankton were collected from a local lake and cultured until the third generation. Neonates of each species were exposed to atrazine at 0, 300, and 3,000 µg/L. The neonates were exposed until their second brood (11+ days) for chronic sub-lethal and lethal endpoints of atrazine exposure. *Lathonura rectirostris* experienced 100% mortality at 3,000 µg/L atrazine, 25% mortality at 300 µg/L atrazine, and no mortality in the control. *Ceriodaphnia dubia* had no mortality throughout the trial, but experienced growth inhibition before the first brood in the presence of atrazine. *Ceriodaphnia dubia* individuals within both atrazine treatments also exhibited delayed production of the second brood and produced fewer neonates than the control. These results suggest that these zooplankton taxa will experience direct negative effects of atrazine exposure at 300 µg/L and thus atrazine concentrations need to be lower if the community study seeks to assess only indirect effects resulting from inhibition of green algae.

**TP230 Effect characterization of three naphthalene sulfonates (NSAs) freshwater biota and their environmental concentrations in Ontario river sediments**

*K. Matten, University of Guelph; P. Gillis, J. Toito, Environment and Climate Change Canada / Aquatic Contaminants Research Division; D.J. Milani, Environment and Climate Change Canada / Watershed Hydrology and Ecology Research Division; A.J. Bartlett, J. Parrott, V. Balakrishnan, Environment and Climate Change Canada / Aquatic Contaminants Research Division; R.S. Prosser, University of Guelph / School of Environmental Sciences*

Naphthalene sulfonic acids (NSAs) are used extensively in Canadian industries (e.g., dispersant in dyes, rubbers, pesticides or anti-corrosive agent in coatings, gels, sealants) despite the gap in our knowledge of how they may affect aquatic biota upon their introduction to the environment. This study examined the toxicity of three priority NSA congeners; dinonylnaphthalene disulfonic acid (DNDS), barium dinonylnaphthalene sulfonate (BaDNS), and calcium dinonylnaphthalene sulfonate (CaDNS) to some potentially affected aquatic species. Chronic effect characterization was done by exposing organisms via spiked substrates to emulate relevant environmental exposure routes, as these chemicals have a relatively large affinity for organic carbon (log Koc). The 28-d LC50s for juvenile *Hyalella azteca* in sand were >500, 113, and 69 µg/g dry weight (dw), and in sediment were >2000, 832, and 648 µg/g dw, for DNDS, BaDNS, and CaDNS, respectively. Mortality was not a sensitive indicator of toxicity for *Tubifex tubifex*, so we instead examined the more sensitive endpoint, juvenile production. The 28-d EC50s in sand were 638, < 20, and < 20 µg/g dw, and in sediment were 2336, 398, and 205 µg/g dw, for DNDS, BaDNS, and CaDNS, respectively. All endpoints from every exposure scenario indicated that the NSAs examined were significantly more toxic to aquatic biota when present in substrates of lower organic carbon (e.g., sand); the organic carbon content of the sediment (2% in the current study) appears to have acted as a sink for NSAs and reduced their bioavailability and thus toxicity. Interspecies differences in toxicity may be the result of differences in benthic zone occupancy as well as in diet. To represent watersheds where there may not be high levels of organic carbon, acute water-only exposures were conducted with glochidia of the pocketbook mussel (*Lampsilis cardium*), the adult ramshorn snail (*Planorbella pilsbryi*), and a juvenile amphipod (*H. azteca*). As little is known about the environmental concentrations of NSAs, sediment samples were collected from 15 river sites across southern Ontario, some of which are located downstream of wastewater treatment plants. These results will be discussed in the context of observed toxicity in the laboratory to provide environmental relevance. This study will support the aquatic risk assessment of this group of chemicals in Canada.

**TP231 Effect-based analyses of complex contaminant mixtures present in agricultural water, using *Daphnia magna* and *Pimephales promelas***

*S. Stinson, University of California, Davis / VMAPC; X. Deng, California EPA / Surface Water Protection Program; R.E. Connon, University of California, Davis / Anatomy, Physiology & Cell Biology / School of Veterinary Medicine*

Agricultural runoff often contains dynamic and complex mixtures of pesticides that can affect aquatic organisms. Multiple pesticides are routinely detected in creeks that receive agricultural runoff. Amongst these, two emerging insecticides of concern, Chlorantraniliprole and Imidacloprid, have been associated with high mortalities. These insecticides possess novel modes of action, and their sublethal effects on aquatic organisms (invertebrates and fish) are not well characterized. This study investigates effects of complex chemical mixtures on an aquatic invertebrate and fish species, at environmentally relevant concentrations. Agricultural water samples were collected from sites prioritized by the Department of Pesticide Regulations (DPR) for surface water monitoring. Acute toxicity (96h exposure) tests were conducted on the two test species (*Daphnia magna*and Fathead minnows; *Pimephales promelas*). Expression of genes associated with metabolism, nervous system function, and general stress response were evaluated in both species. Two of six tested sites resulted in 100% *D. magna*mortality. These same sites resulted in approximately 10% mortality to *P. promelas.*Altered gene expression was determined for both species. For *D. magna*, there was up to 0.35-fold downregulation of *catalase*(oxidative stress), and variable responses across sites in SERCA1, involved in muscle function; up to 1.74-fold upregulation in some sites, but downregulated up to 0.4-fold in another site sample. Similarly for *P. promelas*, genes associated with calcium signaling or neurological function (*VGCC /CaV1.1 L-type*) were downregulated up 0.11-fold, while a gene involved in involved in DNA repair (*ogg1*) was upregulated up to 3.1-fold in some site samples. Understanding sublethal effects posed by exposure to emerging contaminants of concern is an often-overlooked component of the environmental toxicology toolkit. Research done using environmentally realistic concentrations of multiple contaminants is necessary to accurately assess deleterious effects in a dynamic environment. Further research is required, however, to elucidate the effect of individual chemicals present in agricultural creeks. Here we present analytical chemistry as well as effect-based data from exposure to ambient water samples impacted by agriculture.

**TP232 Effects of binary mixtures between broad class of antibiotics and the azole fungicide in growth inhibition testing of the green alga *P. subcapitata***

*T. Yamagishi, National Institute for Environmental Studies; N. Tatarazako, Ehime University / Center for Health and Environmental Risk Research; H. Yamamoto, National Institute for Environmental Studies / Center for Health and Environmental Risk Research*

In most cases, ecotoxicological tests are performed by using individual chemicals. However, since a number of chemicals inevitably coexist in the environment, organisms are exposed to many chemicals simultaneously.

Therefore, tests that use several combined chemicals should be performed to predict effects on actual ecosystems. Currently, antibiotics are detected frequently in the aquatic environment as results of their increased use in humans and animal livestock disease and their incomplete removal by various wastewater treatment processes. The potential environmental impacts of antibiotics must therefore be evaluated similar to those of other chemicals. Generally, antibiotics principally influence the growth of prokaryotes rather than that of eukaryotes. However, macrolides such as erythromycin and clarithromycin have been shown to strongly inhibit eukaryotic algal growth in ecotoxicological studies using the green alga, *Pseudokirchneriella subcapitata*. Azole fungicides, which inhibit the ergosterol biosynthesis pathway, are used widely as both topical and oral pharmaceuticals. As with antibiotics, they are frequently detected in the surface waters and sediments of the aquatic environment. Besides their inhibitory effects on the ergosterol biosynthesis pathway, azoles such as ketoconazole, fluconazole, and miconazole inhibit some species of cytochrome P450s (CYPs), and the interactions between azole fungicides and other drugs metabolized by CYPs have therefore been known well in animals. In algae, the interactions of azole fungicides and other drugs metabolized by CYPs have not been known so far, but it may provide synergism as in animals because algae have been reported to have greater family of CYPs than animals. Here, we investigated effects of binary mixtures between an azole fungicide ketoconazole and broad class of antibiotics (macrolides, lincosamides, tetracyclines, amphenicols and aminoglycosides) on algal growth. Combination index plots, isobolograms, and curve-shift analyses revealed that the combination of ketoconazole and all the selected antibiotics except for neomycin at various ratios resulted in strong synergism that enhanced growth inhibition of *P. subcapitata*, suggesting the existence of antibiotics metabolic pathway by ketoconazole-targeting CYPs in *P. subcapitata*, as existing in animals. However, identification of the species of CYPs targeted by ketoconazole still remains unclear and need to be investigated in the future.

**TP233 Evaluating the combined toxicity of metals and metal-oxide nanoparticles in marine microalgae**

*R.B. Ogunjemilusi, University of Bristol / School of Biological Sciences*

Coastal aquatic ecosystems such as estuaries are at risk of metal pollution due to anthropogenic inputs from acid mine drainage, industrial and agricultural run-off. In addition, advances in nanotechnology in the last decade have increased the production of engineered nanomaterials (ENMs) used widely in fields such as medicine, energy, agriculture, consumer and house-hold goods manufacture. As a result, there are increasing concerns about the release of ENMs such as metal nanoparticles into the environment. While the effect of metals and some ENMs as single contaminants have been extensively studied, much research is needed to account for the potential mixture effects due to heavy metal-ENMs interactions. Studies suggest that the toxicity of metal-oxide nanoparticles is mainly due to the release of dissolved metal ions. However, majority of these studies have mainly focused on impact of ENMs in freshwater environment and results are extrapolated or other types of environmental systems (marine, soil, sediment). Evidence is accumulating that the dissolution of ENMs is dependent on the characteristics of the exposure medium. Metal-oxide nanoparticles tend to form aggregates in seawater medium, reducing the amount of released ions. In this research, the combined toxicity of heavy metals (Cu and Zn) and their metallic oxide nanoparticles (CuO and ZnO) will be evaluated in two marine microalgae – *Cylindrotheca closterium* and *Phaeodactylum tricornutum*. We hypothesize that the aggregates formed by the metal-oxide nanoparticles may adsorb the free metal ions, reducing the bioavailable fraction of heavy metal ions in the exposure medium. Because of intrinsic ecological differences in both microalgae; *C. closterium* having a bottom dwelling nature and *P. tricornutum* mainly planktonic, we also investigate if toxic response may be due to differential mechanism of toxicity. For instance, reduced light intensity as a result of ENMs aggregation may be expected to be more prevalent in benthic microalgae-ENMs exposure than in test systems containing planktonic algae exposed to ENMs.

**TP234 Evaluating the toxicity of California stream sediments with the amphipod *Hyalella azteca*, the midge *Chironomus dilutus***

*N.E. Kemble, USGS / Biological Resources Division / Columbia Environmental Research Center; J.A. Steevens, USGS / Columbia Environmental Research Center; P.W. Moran, USGS/ Washington Water Science Center; P.C. Van Metre, USGS / Texas Water Science Center; L.H. Nowell, USGS / California Water Science Center*

As part of the US Geological Survey's National Water-Quality Assessment Program (NAWQA), 81 stream sediment samples representative of urban, agricultural and mixed land use in coastal, central California, were collected in the spring of 2017 to be evaluated under the Regional Stream Quality Assessment project. Relationships between biological conditions and concentrations of contaminants, metals, pesticides, PAHs, nutrients, and sediment in streams from the state of California were evaluated by conducting whole-sediment toxicity tests. The sediments were tested in accordance with ASTM and USEPA methods for conducting sediment toxicity tests with the amphipod *Hyalella azteca* (28-d exposure; 81 samples), and the midge *Chironomus dilutus* (10-d exposure; 40 samples). Toxicity endpoints included survival, weight, and biomass. Mean control survival at the end of the exposures met test acceptability criteria. Sixty-two percent of the sediments (50 of 81 sites) were toxic to at least one of the test species, as determined by a significant reduction of at least one endpoint relative to the control sediment. Amphipod exposures identified 44% (43 of 81 sites) of the sediment samples as toxic. Midge exposures identified 48% (19 of 40 sites) of the sediments as toxic. Results from the 2017 study in California will be compared to the other NAWQA regional sediment-toxicity surveys conducted in the Midwest (2013), the Southeast (2014), the Pacific Northwest (2015) and the Northeast (2016). Five major classes of sediment pollutants were measured in these stream sediments, Organochlorines, PAHs, total PCBs, metals, and current use pesticides. Ongoing efforts will be presented, including development of a reference envelope approach to compare organism response to reference sediments, and comparisons between sediment toxicity and sediment chemistry.

**TP235 Fate and Effects of a Copper-Based Algaecide to Mitigate a Recent Invasion of *Nitellopsis obtusa* (Starry Stonewort) in Lake Sylvia, Minnesota**

*T. Geer, Clemson Univeristy / Department of Forestry and Environmental Conservation; S. McComas, Blue Water Science; J. Rodgers, Clemson University / Department of Forestry and Environmental Conservation*

Pulse algaecide exposures are intentional inputs of pesticides into water resources to mitigate algae that impede or threaten to impede uses of the water resource (e.g. recreation). Risks for non-target (i.e. native) algae and macrophytes occur when these organisms co-occur with the deleterious alga(e) targeted by an algaecide exposure. *Nitellopsis obtusa* (Desvaux in Loiseleur) J. Groves (starry stonewort) is a non-indigenous alga in North America that spread rapidly among inland lakes across the Great Lakes region of the U.S. A copper-based algaecide was used in Lake Sylvia (Wright Co. MN) to mitigate potential impacts of a recently established population of *N. obtusa*. To inform risk management decisions for *N. obtusa* in the U.S., overall objectives of this study were to 1) measure and compare responses of *N. obtusa* and co-occurring native macrophytes to algaecide exposures in the area of Lake Sylvia infested with *N. obtusa*, and 2) to compare risks of mitigated *N. obtusa* in Lake Sylvia with an unmitigated population in a nearby water resource (i.e. Lake Koronis, southwestern Stearns County). A chelated copper-based algaecide was applied 4-times between June 21 and October 17, 2017, in a 0.65-hectare area around the boat access in Lake Sylvia, in response to sprouting *N. obtusa* bulbils. Copper concentrations measured immediately after each algaecide application were >90% of the intended initial concentration (1000 µg Cu/L in the bottom 0.61 m of the water column), and post-treatment dissipation followed first order rate kinetics. Half-lives of copper exposures were between 10.9 and 12.8 h. As a result of algaecide exposures, the occurrence of *N. obtusa* in rake samples in the treated area declined significantly from May (21.3% occurrence) to October (0.0%

occurrence). Decreases in the density of *N. obtusa* bulbils (bulbils/m$^2$) in the treated area were also measured. In contrast to Lake Sylvia, occurrence of unmitigated *N. obtusa* in rake samples in Lake Koronis was between 80% and 100% (n=15) during the same time period (i.e. May to October). Although changes in the occurrence of some native macrophyte taxa were measured in Lake Sylvia, the cumulative occurrence of all native macrophyte taxa did not change significantly in the treatment area as a result of algaecide applications. The results of this study indicate that algaecide exposures can mitigate risks associated with *N. obtusa*, while risks for non-target macrophytes and algae are minimal.

**TP236 Heavy Concentrations in Some Fresh Fishes near an Electronic Waste Dumpsite (Agbogbloshie) and a Control Site (Asesewa) in Ghana**

*S.A. Takyi, University of Ghana; J. Fobil, J. Arko-Mensah, University of Ghana / Biological, Environmental and Occupational Health Sciences; N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences; T. Robbins, University of Michigan, Ann Arbor; A. Amoabeng-Nti, University of Ghana / Biological, Environmental and Occupational Health Sciences*

Background: Processing of electronic waste could result in release of toxic chemicals including heavy metals into the surrounding environment. These toxic substances could end up in the food chain, including vegetables and fish over time. Elevated levels of toxic heavy metals in food could have direct adverse health implications for humans. This study assessed and compared concentrations of Pb, Hg, As and Zn in selected fish species from Korle-Lagoon (main site), near the Agbogbloshie e-waste processing/dumpsite and the Volta Lake (control site). Methods: Concentration of heavy metals in fish except Hg was determined using Inductively Coupled Plasma Mass Spectrometry (ICP-MS). Mercury (Hg) in fish was measured using the Direct Mercury Analyser (DMA). Statistical analysis was done using SPSS version 22 and reported in means and standard deviations. Results: In total, 84 fish tissues (muscle, liver and gill) were analyzed. The *Ameiurus catus* from the Korle-Lagoon hadhigh levels of Pb (0.62±0.65 µg/g dry wt) and Zn (154.21±143.51 µg/g dry wt) whilst the *Hepsetus odoe* from thesame sitehad the highest concentration of As. However, the *Hepsetus odoe* from the Volta Lake had highest level of Hg (1.08±1.22 µg/g dry wt).High concentrations of As and Zn were observed in the three tissues with Pb levels only high in the liver and gills. Between sites, the Korle-Lagoon recorded higher levels of Pb, As and Zn in fishes sampled. High Hg (0.62±0.97 µg/g dry wt) concentrations was found in fish from the Volta Lake. Conclusion: Irrespective of site, the *Ameiurus catus* had high levels of Pb and Zn whilst the *Hepsetus odoe* high levels of As and these were above permissible limits according to the WHO standards.The liver and gills had high levels of As, Pb and Zn. Overall, these fish species were not considered safe for human consumption.

**TP237 Impact of low-concentrated chemical mixtures on zebrafish embryos (*D.rerio*)**

*G. Jakobs, Helmholtz Centre for Environmental Research – UFZ / Department Bioanalytical Ecotoxicology; J. Krüger, Helmholtz Center for Environmental Research UFZ GmbH; R. Altenburger, W. Busch, Helmholtz Centre for Environmental Research – UFZ GmbH / Bioanalytical Ecotoxicology*

Recent environmental monitoring studies indicated that aquatic micropollutants occur in multitudes of low-concentrated chemicals. The joint effect of low-concentrated chemical mixtures is discussed as potential cause for low ecosystem quality. Even mixtures containing only chemicals below their individual no observed effect concentration (NOEC) can cause combined adverse effects (principle "something from nothing"). Whether this can be detected or even predicted in complex model organisms, such as the zebrafish embryo (ZFE), was investigated in this study. Therefore we analyzed the impact of low-concentrated chemical mixtures on *D.rerio* embryos and the predictive power of two available mixture toxicity prediction concepts – the model of Concentration Addition (CA) and Independent Action (IA). For this reason, ZFE were exposed to several single substances in various concentrations, hence adverse effects recorded and dose-response curves (DRC) calculated. Subsequently, single substance toxicity data were used to model five individual mixtures. Two mixtures were prepared to investigate the CA model, hence containing similarly acting substances. Another two mixtures were analogously prepared which contained dissimilarly acting components, thus addressing different modes of action and the IA model. Here, an equitoxic design was chosen at which selected chemicals were mixed in their individual $LC_{10}$ values obtained after exposing ZFE for two different treatment periods (0-48hpf and 24-72hpf). To scratch limits at which a remarkable adverse effect induced by low-concentrated chemical mixtures is detectable, a fifth mixture consisting of 13 environmentally relevant chemicals, mixed in their individual NOEC ($LC_0$-$LC_{0.1}$), was investigated. After exposing ZFE to different mixtures, observed mixture toxicity was elucidated and obtained DRC compared to predicted mixture effects. In summary, results revealed a joint mixture effect for all tested mixtures. More precisely, mixture effects appeared always within the prediction window of the CA and IA model. The IA model usually underestimated the mixture effect whereas the CA model had higher predicted power. Altogether, a concerning joint mortality up to 90-100% was reached even if components were applied in NOEC or low-dose concentrations ($LC_0$-$LC_{0.1;}$ $LC_{10}$).

**TP238 Impact of Polystyrene Microsphere Ingestion Indicating Internal Styrene Leaching using *Orconectes virilis* as a Model**

*J. Randall, Marist College / Environmental Science; Z. Gagnon, Marist College / School of Science*

The ingestion of microplastics is a relatively new ecological and human health concern. Plastic microbeads, which rarely exceed 1.0mm in diameter, are now commonly used in cosmetic products. Due to the inability of many U.S. wastewater treatment plants to remove microbeads, these plastics are released within effluent into local bodies of water. Ingestion and tissue accumulation of microplastics has been identified within a wide variety of aquatic organisms, including decapod crustaceans. However, little is known about the toxic effects of these microscopic synthetic polymers upon ingestion. This study investigated the toxicity of 10mm and 45mm diameter polystyrene microspheres, sizes commonly found in cosmetic products, on *Orconectes virilis*, a Hudson River native crayfish species. Four exposure and three control treatments were established: 10mm polystyrene microspheres in a low and high concentration, 45mm microspheres in a low and high concentration, stationary control, Hudson River water flow through control, and Hudson River cage control. Each glass aquaria or cage contained two male and two female crayfish for a 14-day exposure period before harvesting. Significantly higher levels of DNA damage within the hepatopancreas were seen in exposure groups compared to controls. Slight variations of $Ca^{2+}$ and $Fe^{2+}$ concentrations were seen in both exoskeleton and hepatopancreas tissue between control and exposed crayfish. Differences in response intensity during the experimental period were insignificant, however, 62.5% of exposed crayfish underwent ecdysis compared to 25% of control crayfish. Pathological differences of hepatopancreas and exoskeleton tissue were evident as hepatocyte cells displayed higher levels of vacuolization, cell hypertrophy, and cell membrane degradation in exposure groups, as well as demineralization and undefined layering of the exoskeleton. These results correlate with literature regarding the toxic effects from exposure to the monomer styrene, which can be found within the polystyrene matrix and leached from the polymer in the presence of high temperature, acids, oils, and other compounds. This study's findings suggest that styrene may be leached internally, after polystyrene ingestion. This not only poses a threat to aquatic organisms and ecosystem health, but also to human health as crustaceans are commonly consumed worldwide.

**TP239 Impacts of water quality parameters in an agriculturally dominated watershed: Bayou DeView, Arkansas**

*A.L. Ruby, Arkansas State University / Environmental Science; J. Bouldin, Arkansas State University / Ecotoxicology Research Facility*

Bayou DeView Watershed, a tributary of the Cache River located in northeastern Arkansas, provides a variety of important ecosystem services. Watersheds provide ecosystem services including climate and disturbance regulation, water regulation and supply, erosion control, nutrient and waste cycling, and aesthetic and recreational values. Disruption of watershed functioning from impairment largely results from anthropogenic activities. Impairment can result in decreased biodiversity, the creation of hypoxic zones, and ecosystem death. Bayou DeView is characterized as a channel-altered Delta Ecoregion stream. Channelization refers to the deliberate straightening of streams and rivers that usually involves removing meanders, widening, and dredging the stream channel. Channel modification increases total suspended solids, nutrient run-off, and alters diversity of flora and aquatic fauna.Possessing a high diversity of pollutant tolerant aquatic organisms, Bayou DeView offers near permanent surface water habitat and agricultural irrigation supply. Bayou DeView is impaired by excess sedimentation. Seven sites selected within Bayou DeView Watershed were sampled weekly for physiochemical and nutrient water parameters. Analysis of parameters were performed as a function of monitoring site, season, agricultural cropland percentage, and stream order. Physiochemical parameters were significantly different among sites ($p< 0.01$). Seasonality significantly affected temperature and total phosphorus levels ($p=0.02$; $p=0.001$). Agricultural cropland percentage and stream order were not significantly related to any physiochemical water quality parameters ($p>0.05$). Continued consistent monitoring and assessment of surface water in Bayou DeView Watershed is vital in preserving ecosystem services and assist in the implementation of best management practices.

**TP240 Influence of Post Hatching Age on the Sensitivity of Zebrafish (*Danio rerio*) Acute Toxicity Test**

*A. Arenzon, Federal University of Rio Grande do Sul / Ecology Center / Ecotoxicology Lab; N. Reichert Machado, Federal University of Rio Grande do Sul / Ecology*

Acute fish toxicity (AFT) test have been used in many countries for effluent risk assessment and/or ecotoxicological monitoring. Within it, a relevant number of countries have used OECD 203 – or some national standard protocol with minor differences like Brazilian NBR ISO 15088 – as a standard method. This protocol determines the usage of juvenile/adults fish within a specific length size (2 ± 1 cm) that may not be directly associated with organism's age. Some studies have suggested a clear decrease in sensitivity to pollutants along the organism lifetime, resulting in a higher sensitivity of larvae when compared to adults. Summing up, tests with adults require a large volume of tested solution (chemicals, effluent…) when compared to larval tests, resulting in logistic costs. Due to that, the Environmental Protection Agency (USEPA) recommends that toxicity tests should be performed with organisms that are in the early stages of development, ensuring the most sensitive stage to be tested. The objective of this research is to strictly determine the optimal age for the acute fish test using zebrafish (*Danio rerio*) as a model. Fish were reproduced in the laboratory and nurtured with *Paramecium* sp. *Ad libitim* until 2 hours prior testing. Toxicity tests were performed in replicate for organisms aging from 2 to 24 days post-hatching using Potassium Chloride (KCL) as the reference solution. Until the moment, 45 tests were performed. Organisms were exposed to the reference solution for 48 hours in a static renewal system and kept at 25 ± 2 °C. LC50:48h were determined using Trimmed Spearman-Karber 1.5 Software. The sensitivity curve presents a clear increase in zebrafish sensitivity to KCl between the 4th and 14th day of life. Notwithstanding, further studies aiming other reference solutions still need to be concluded.

**TP241 Inhibition Growth Effect of Sunscreen UV Filters on the Freshwater Microalga *Scenedesmus acutus***

*T. Walton, J.B. Belden, Oklahoma State University / Integrative Biology*

As the use of personal cosmetic care products (PCCPs) with organic ultraviolet (UV) filters are increasing, so is the exposure risk of these compounds to aquatic ecosystems. This study focuses on the inhibition growth effect of 6 common UV filters found in PCCPs on the freshwater microalga, *Scenedesmus acutus.* Fluorescence of chlorophyll was used as a measure of growth during a 96-h exposure period and growth inhibition was utilized as the endpoint. All UV filters inhibited growth with increasing concentration, except for avobenzone, which did not decrease reproduction at any treatment level up to water solubility. Lowest observed effect concentrations were greater than 100 ppb without UV light. Homosalate was the most toxic and avobenzone was the least toxic. Further testing will compare each of the UV filters under UVA and non-UVA conditions to see if UVA radiation increases toxicity.

**TP242 Laboratory Evaluation of Impacts of Exposure Concentration and Duration on Forestry Herbicide Toxicity to Aquatic Plants and Algae**

*D. Simning, W. Arthurs, J. Ikoma, V.L. Tatum, C. Flinders, NCASI*

The use of herbicides to control competing vegetation during stand establishment is a key component of intensive silviculture. Although some field studies have shown that the use of modern best management practices is effective at reducing the movement of applied herbicides into forest streams, peak stream water concentrations of some herbicides still exceed no observed effects concentrations (NOEC) for some aquatic plants. Exposure duration is a key factor in determining the magnitude of effects of herbicides on aquatic plants. Following forestry herbicide application, herbicide concentrations in forest streams have been shown to "pulse" in response to storm runoff, with peak concentrations persisting for brief periods of time. Since the studies from which NOEC values are derived are typically based on 7- or 14-day continuous exposures, the short-term exposures associated with forestry herbicide may represent a significant mitigating factor in actual toxicity to aquatic plants. We used a hybrid approach to quantify the duration-exposure concentration-toxicity relationship for herbicide mixtures and aquatic plants (*Lemna gibba*; OCSPP 850.4400: Aquatic Plant Toxicity Test Using Lemna spp.) and algae (*Raphidocelis subcapitata*; OCSPP 850.4500: Algal Toxicity), and evaluated recovery from exposure of varying durations. Measured endpoints included growth measured as RFU (*Raphidocelis*), and as frond area, counts and biomass (wet and dry mass; *Lemna*). Selected herbicides and mixture ratios represented those most commonly used based on application area in the southeast and Pacific Northwest regions of the US (Glyphosate, Imazapyr, Metsulfuron, Sulfometuron, Hexazinone), with the highest test concentrations calculated using the US Forest Service Risk Assessment of upper peak concentration (mg/L per application of 1 lb/acre) and the highest application rate used by the industry. We describe species-specific test methods and preliminary findings for both taxa.

**TP243 Light emitting diode can be used for green alga growth inhibition tests**

*T. Matsumoto, A. Okamoto, Y. Imamura, Nisso Chemical Analysis Service Co., Ltd. / Department of Ecotoxicology*

Alga growth inhibition tests are commonly performed by using a growth chamber with fluorescent lamp (FL) as a lighting source because the test guidelines require continuous lighting with uniform fluorescent illumination. Recent growth chambers, however, are equipped with a light emitting diode (LED) instead of a FL because of the restriction for mercury-added products by the Minamata Convention adopted in 2013. Although both FL and LED have the photosynthetically effective wavelength range of 400-700 and can provide an adequate light intensity according to the guidelines, qualities of light, such as color, intensity of each wavelength, range of wavelength, and so on, are slightly different between them. We investigated the qualities of light from LED and FL and conduced the growth inhibition tests of five kinds of chemicals in a unicellular green alga *Pseudokirchneriella subcapitata* with LED and FL to confirm whether LED can be used as a substitute for FL. Sodium chloride, cadmium chloride, potassium dichromate, 3,5-dichlorophenol and pentachlorophenol were used for the tests because these chemicals have different modes of actions and are assigned as reference substances in the test guidelines. The results showed no difference in the growth inhibition rates and yield inhibition rates between the LED and FL conditions. Moreover, ErCx, EyCx and NOEC values of each chemical under the LED condition showed similar values to the FL conditions. In conclusion, LED instead of FL as a lighting source did not affect the results of the growth inhibition tests with the green alga. Therefore the test guidelines may need to be revised to allow the use of LED though we need to investigate the effects of LED for the other algae, cyanobacteria, diatoms, and marine algae.

**TP244 Long-term ecological effects on infauna communities of wastewater effluent from wastewater treatment processes in Southern California**

*J. Zhang, N.E. Andrzejczyk, University of California, Riverside / Department of Enviromental Sciences; D. Tang, K.A. Sakamoto, J.L. Armstrong, Orange County Sanitation District / Environmental Laboratory and Ocean Montoring; D. Schlenk, University of California, Riverside / Department of Environmental Sciences*

In the last 16 years, the Orange County Sanitation District (OCSD) commenced effluent disinfection by chlorination in 2002 and full secondary treatment in 2012 to improve the water quality of effluent, and partnered with the Orange County Water District on the Ground Water Replenishment System (GWRS) water reclamation project in 2008 to mitigate the water resource crisis in California. To assess the ecological impacts of these processes, the infauna community was monitored off the coast of Huntington Beach, California, from 1991 to 2016. Results showed the Infaunal Trophic Index (ITI) and Benthic Response Index (BRI) at the monitoring station near the OCSD outfall were stable between "normal community" and "changed community" levels from 1991 to 2001. However, after chlorination began in 2002 the infauna community near the outfall became degraded, with ITI falling sharply after 2008 to the lowest value in 2010. However, when full secondary treatment was achieved in 2012, in combination with a substantial reduction of chlorine use in the treatment process, the infauna community quickly recovered to pre-chlorination levels. In contrast to the outfall site, the reference location remained unchanged throughout this duration. Changes of both ITI and BRI near the OCSD outfall before 2012 were correlated with chlorine usage and a decrease in final effluent flow rate, which were not observed at the reference site. These results indicated that disinfection by chlorination and the GWRS were harmful to infauna communities, with associations to chlorine use low-flow periods.

**TP245 Monitoring Water Quality in Eight Subwatersheds of the Strawberry River**

*A. Alves Augusto, Ecotoxicology Research Facility / Biological Sciences; I. Sanchez Gonzalez, J.L. Bouldin, Arkansas State University / Biological Sciences*

The Strawberry River is a tributary of the Black River within the White River basin in northernArkansas. The river distance from source to mouth is about 177 km, and it is considered by the ADEQ as an extraordinary resource and ecologically sensitive waterway. In order to protect the water quality, it is important to determine which tributary is adding to the impairment due to siltation. Water quality in eight tributaries (Piney Fork, Mill Creek South Big Creek, North Big Creek, Clayton Creek, East Cooper Creek, Reeds Creek, Sleep Bank Creek, and Caney Creek) are collected prior to the confluence with the Strawberry River. Water quality variables include total suspended solids (TSS), turbidity, pH, conductivity, dissolved oxygen, PO4, TN TP, NO2-, and NO3. Turbidity values range from 0.76 to 64.8 Nephelometric Turbidity Unit (NTU) and TSS values range from 1.6 to 73.6 mg/L. This ongoing project will help understand the water quality of the Strawberry River and the eight subwatersheds analyzed. Additional data for this project include assessment of fish communities in the Strawberry River. The river supports over 100 species of fish, and protection of fish and other indigenous species is important to understand how the water quality impacts the species and their habitats.

**TP246 Occurrence of pharmaceuticals at high concentrations in Nigerian rivers**

*O. Ogunbanwo, P. Kay, L. Brown, University of Leeds / School of Geography; J. Wilkinson, The University of York / Natural and Built Environments; A. Boxall, University of York / Environment Department; J. Sinclair, LGL Limited*

Pharmaceutical contamination of surface waters is increasingly recognized as a global problem, but to date there remains a scarcity of data from many African countries. The occurrence of 37 pharmaceuticals belonging to 19 therapeutic classes was studied in surface water and effluent in Lagos State, Southwest Nigeria. Samples were collected year-round from 22 sites, and 27 compounds were detected at least once, many in the microgram per litre range. Maximum concentrations for a range of compounds including sulfamethoxazole, paracetamol, cimetidine, fexofenadine, carbamazepine, metformin and diazepam ranged from 75031 ng $L^{-1}$ to 129474 ng $L^{-1}$ in areas receiving untreated sewage and pharmaceutical manufacturing plant discharges. Mean concentrations for 13 compounds were in the mg $L^{-1}$ order. These values are several orders of magnitude higher than most studies of pharmaceutical occurrence in Europe and North America but similar to some other peak concentrations measured in developing countries such as China and India. Multiple pharmaceutical compounds were found at all monitoring sites although there were few clear spatial patterns. This may indicate that a variety of pharmaceutical sources exist throughout the catchment, including manufacturing facilities, sewage treatment plants, vacuum trucks that discharge sewage to rivers and urban areas where sewage treatment is not provided. AbSeasonal variations in concentrations were observed for certain pharmaceuticals such as fexofenadine, carbamazepine, paracetamol, cimetidine, metformin, sulfamethoxazole, atenolol, diazepam, codeine, and trimethoprim which may be related to the environmental conditions that affect dilution and degradation and/or seasonal manufacturing and usage. Pharmaceuticals are indispensable to human health although their usage and discharge into the aquatic environment may lead to ecological problems and antibiotic resistance. African governments may need to enact policies to remedy losses to rivers urgently.

**TP247 Oxidative stress produced by aluminum nanoparticles in liver and blood of *Cyprinus carpio***

*M. Galar-Martinez, S. Cano-Viveros, Escuela Nacional de Ciencias Biológicas / Instituto Politécnico Nacional; S. Garcia-Medina, Escuela Nacional de Ciencias Biológicas / Instituto Politécnico Nacional / Laboratory of Aquatic Toxicology / Department of Pharmacy; E. Gasca-Pérez, Escuela Nacional de Ciencias Biológicas / Instituto Politécnico Nacional; L.M. Gómez-Oliván, Universidad Autonoma del Estado de Mexico / Farmacia; K. Ruiz-Lara, Escuela Nacional de Ciencias Biológicas / Instituto Politécnico Nacional / Laboratory of Aquatic Toxicology / Department of Pharmacy; D. Cruz- García, A. Flores-Vega, Escuela Nacional de Ciencias Biológicas / Instituto Politécnico Nacional*

The use of nanoparticles in various industries has experienced an important growth due to the advantages they offer, so the increase in their use has generated the continuous discharge of these products in numerous water bodies, and may affect the organisms that inhabit them. Aluminum (Al) is one of the chemical elements that is abundantly produced in particles of nanometric size, having an important application in the pharmaceutical industry. Previous studies have shown that Al is capable of producing oxidative stress in mammals and aquatic organisms, however, so far there are no studies on the impact of Al nanoparticles on hydrobionts, such as *Cyprinus carpio*, a species widely distributed and of great ecological, commercial and food importance in Mexico. Therefore, the objective of this work was to determine the oxidative stress produced by

Al nanoparticles in liver and blood of *C. carpio*. For this, the organisms were exposed to the xenobiotic at a concentration of 50 μg/L for 12, 24, 48, 72 and 96 h, with n=4 for triplicate. Subsequently, 0.5 mL of blood sample was obtained by puncture of the caudal vein and euthanasia of the organisms for the extraction of liver. The determination of oxidative stress was performed by evaluating the degree of lipoperoxidation, the content of hydroperoxides and oxidized proteins, as well as the activity of the antioxidant enzymes superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx). The results showed alterations in the activity of the antioxidant enzymes as well as damages in lipids and proteins in both organs.

### TP248 Platinum group element exposure to macro-invertebrates from a river impacted by platinum mine effluent

*J.H. Erasmus, North-West University / Environmental Sciences and Management; B. Sures, S. Zimmermann, University of Duisburg, Essen / Aquatic Ecology; W. Malherbe, V. Wepener, N. Smit, North-West University / Environmental Sciences and Management*

South Africa is the world's main supplier of platinum group elements (PGE), which include platinum, palladium and rhodium. The Bushveld Igneous Complex in South Africa contains 75, 52 and 82 % of the world's platinum, palladium and rhodium resources, respectively. The mining of these precious metals requires large volumes of water for production and the removal of waste products. Most of this waste water is discharged into river systems, which can have a detrimental effect on the aquatic ecosystem. Although the input of PGE by mining activities to aquatic systems are known, little to no information is available on the influence of the PGE input on aquatic taxa in these systems. However, the uptake and bioaccumulation of PGE by aquatic animals has been clearly demonstrated in laboratory investigations, as well as field studies from non-mining areas. The aim of this study was to determine the bioaccumulation of metals associated with PGE mining in different macro-invertebrate families. Water, sediment and macro-invertebrate samples were collected from a reference, moderately impacted and highly impacted site. The macro-invertebrates and sediment were prepared and concentrations of Pt, Pd, Cr, Co, Cu and Ni in water, sediment and macro-invertebrates were determined with inductively coupled plasma mass spectrometry analysis (ICP-MS). The macro-invertebrates accumulated metals associated with PGE mining and with benthic and epi-benthic dwelling taxa (Tubificidae) accumulating higher Pt, Pd and Cr concentrations than other families (e.g. Potamonautidae, Coenagrionidae and Lymnaeidae). These results provide valuable information on the exposure of PGE mining effluent in the aquatic ecosystems and therefore the risk assessment of these intensive mining activities.

### TP249 Presence of Fecal Bacteria and Associated Pathogens at Recreational Freshwater Beaches in Tennessee, USA

*A.C. Todd, Middle Tennessee State University / Biology; J. Jatko, Clemson Institute of Environmental Toxicology / Biological Sciences; D. Chan, Middle Tennessee State University / Biology; M. Stallard, Middle Tennessee State University; F.C. Bailey, Middle Tennessee State University / Department of Biology*

Fecal indicator bacteria (FIB) have been found in high quantities in the sand of marine and freshwater beaches. Tennessee has more than 30 freshwater lakes and reservoirs, many containing human-made, sandy beaches for recreational use. Although fecal bacteria and associated pathogens in fresh-water beach sand pose a potential risk to the visitors at these recreational areas, as of now there are no federal guidelines for the regulation of fecal bacteria in sand at freshwater beaches. The objective of this study is to assess the abundance of fecal indicators (*E. coli*, coliphages, *Bacteroidales*) and associated pathogens (Methicillin Resistant *Staphylococcus aureus*, MRSA) in freshwater beach sand and water at two central Tennessee recreational beaches. Six sampling events will occur during the summer recreational season in 2018. Three of these events are on major, national holidays which coincide with increased human activity at the beaches. On each sampling date, sand core samples were taken to a depth of ~10 cm at 5 locations in the swash zone at each site using sterile PVC pipe, and water samples were taken at 3 locations in 0.5M deep water using sterile 1L plastic bottles. Sand samples (100g aliquots) were shaken in 1L of phosphate buffered saline (PBS) solution to release bacteria from sand particles before processing. For both water and PBS eluents from sand samples, DNA was extracted using DNeasyâ PowerWaterâ Kits and stored at -80°C until processing by qPCR. Concentrations of *E. coli* in water and sand sample eluents were measured using ColilertÒ, coliphages were enumerated using EPA Method 1602, human-specific *Bacteroidales* were measured using a qPCR assay, and MRSA concentrations were determined with selective agar plates and confirmed by qPCR. Initial sampling results show every beach sand and water sample to contain *E. coli*. The *E. coli* concentrations ranged from 20 MPN-1,989 MPN/100g for swash zone sand, but most sand samples contained less than 400 MPN/100g. Water *E. coli* concentrations ranged from 18.5 MPN/100mL to 90.8 MPN/100g. MRSA was found in all sand samples with concentrations from approximately 120 CFU/100g to too numerous to count (TNTC) and in water from 56 CFU/100mL to TNTC. Ongoing qPCR will be used to verify the identity of MRSA on selective agars. These results show the presence of fecal bacteria and pathogens at these two freshwater sandy beaches and demonstrate a potential risk to beachgoers.

### TP250 Quantifying gemfibrozil disinfection byproducts in southern California sediments and using transcriptomics to assess biological effects

*N.E. Andrzejczyk, J. Zhang, University of California, Riverside / Department of Enviromental Sciences; E.D. Nelson, Sanitation Districts of Los Angeles County / SJC Water Quality Lab; S. Dudley, UC Riverside / Environmental Toxicology; J.M. Rimoldi, R.S. Gadepalli, I. Edwards, University of Mississippi / Department of Biomolecular Sciences; K.A. Sakamoto, J.L. Armstrong, Orange County Sanitation District / Environmental Laboratory and Ocean Montoring; B. Power, Sanitation Districts of Los Angeles County / Ocean Monitoring & Research; J. Gan, D. Schlenk, University of California, Riverside / Department of Environmental Sciences*

Disinfection byproducts (DBPs) are a class of compounds produced from wastewater chemical disinfection. Due to the ubiquitous distribution of DBPs in aquatic environments and water supply systems, there is concern for potential health risks in humans and aquatic organisms. Only 18 DBPs are regulated globally and biological effects of DBPs have been minimally studied, especially those formed from pharmaceutical agents. Chlorination and bromination of the anti-cholesterol pharmaceutical gemfibrozil has been observed in wastewater effluent following chlorination and may pose ecological concerns following halogenation. To better understand occurrence and effects of gemfibrozil DBPs, concentrations of chlorogemfibrozil and bromogemfibrozil in Southern California sediments were quantified and toxicity to aquatic organisms was determined through whole-transcriptome sequencing. Sediment cores were collected at the outfall of Orange County Sanitation District (OCSD) where chlorination began in 2002. Following QuEChERS extraction, concentrations of chlorogemfibrozil and bromogemfibrozil were quantified in sediment extracts. To establish toxicity to aquatic organisms, dose-response experiments were performed for gemfibrozil, chlorogemfibrozil, and bromogemfibrozil using *Neanthes arenaceodentata* through aqueous exposures. *Neanthes* were exposed to chlorogemfibrozil and bromogemfibrozil at concentrations found in sediments for 7 days and whole-transcriptome sequencing was used to characterize toxicological effects of gemfibrozil DBPs. Dose-response results in *Neanthes* with gemfibrozil, chlorogemfibrozil, and bromogemfibrozil yielded LC50 values of 469.85, 46.14, and 17.98 mg/L, respectively. Additionally, preliminary data show 0.01 ppb chlorogemfibrozil and 0.03 ppb bromogemfibrozil in OCSD sediments. The results of this research will examine the occurrence of gemfibrozil, chlorogemfibrozil, and bromogemfibrozil in Southern California sediments and quantify the uptake and biological effects of these DBPs in aquatic organisms.

**TP251 Reproductive health of yellow perch *Perca flavescens* populations in Chesapeake Bay tributaries with varying amounts of development**

*A.H. MacLeod, University of Maryland, College Park / Environmental Science and Technology; N.K. Karouna-Renier, USGS / Patuxent Wildlife Research Center; F.E. Pinkney, U.S. Fish & Wildlife Service / Chesapeake Bay Field Office; V.S. Blazer, USGS / National Fish Health Research Laboratory; E. Haag, University of Maryland / Biology; L.T. Yonkos, University of Maryland / Environmental Science and Technology*

Yellow perch have historically been an economically and culturally important fishery to the Chesapeake Bay. Populations, however, have experienced precipitous declines over the past several decades in many regions of the Bay. These declines correlate inversely with percent imperviousness within catchment areas and therefore appear related to human development in the affected watersheds. Females from affected regions are reported to have a high frequency of gamete abnormalities (e.g., thin and irregular zona pellucida (egg envelope), abnormal yolks, and incomplete development at the time of spawn. Additionally, hatching success from impacted populations has declined markedly from > 80% in 1960 to < 10% between 2001 and 2005. Important stages of reproductive development including follicugenesis and vitellogenesis have not been studied in this species. To that end, we conducted an investigation into the reproductive health of mature male and female yellow perch from several historically important spawning reaches within the Chesapeake Bay watershed. The investigation included areas of varying land use from predominantly agricultural (Choptank River) to moderately (Mattawoman Creek) and substantially (Severn River) suburban/urban. We investigated gonadal histology/histopathology, as well as a battery of molecular biomarkers including plasma vitellogenin, circulating sex steroids (e.g., E2 and T), hormones essential to ovarian maturation (e.g., FSH and LH), gene expression within liver and gonads. Yellow perch were collected at several month intervals prior to and on the spawn from each system to investigate gene expression, molecular signaling, hormone levels, and tissue conditions during the period of reproductive recrudescence. The primary objective of the study was to determine the stage and manner that populations from impacted regions begin to deviate from normal reproductive development. Preliminary data will be presented.

**TP252 Sensitivity of California Freshwater Unionid Mussels to Ammonia**

*B.C. Jorgenson, Pacific EcoRisk*

The inclusion of new toxicity data for freshwater unionid mussels in USEPA's 2013 recommended aquatic life criteria for ammonia resulted in substantially reduced revised national recommended criteria for ammonia; however, the mussel genera included in USEPA's dataset are not resident to the western United States. Species of unionid mussels (*Anodonta*, *Margaritifera*, and *Gonidea* genera) are widely distributed throughout the western United States, yet little is known as to the comparative sensitivity of these resident mussels to ammonia. In order to explore this question, toxicity testing of juvenile *Gonidea angulata* was conducted. Ammonia sensitivity of *Anodonta californiensis* and *Gonidea angulata*is compared to that of other resident species, including *Anodonta oregonensis* and *Margaritifera falcata,* as well to those species represented in USEPA's national dataset for ammonia.

**TP253 Simulation model to study percolation toxicity of pesticides, isolated and in mixtures, in *Raphidocelis subcapitata***

*L.P. Figueiredo, D.B. Athayde, University of São Paulo; R.A. Moreira, Escola de Engenharia de São Carlos / Universidade de São Paulo / SHS Departamento de Hidráulica e Saneamento; M. Daam, CENSE & New University of Lisbon; E. Espindola, University of São Paulo / Hydraulics and Sanitation*

Bom Repouso (MG) is a municipality with agricultural characteristics and the production of potatoes and strawberry is relevant to the local economy. Nevertheless, in these crops farmers are using the acaricide/insecticide Kraft® (abamectin) and the herbicide Score® (difenoconazole), isolate or in mixture, and the ecological effects are not evaluated yet. Considering that, this research was to assess the effects of these pesticides on the Crustacea *Ceriodaphnia silvestrii,* using studies in aquatic ecosystem models. The experiments were conducted in mesocosms (400 L) containing water, sediment and biological community, simulating the environmental conditions. The pesticides (Kraft and Score) were applied in soil without vegetation, according to the dose recommended by the manufacturer for strawberry crops hich was simulated a rain of 19mm. The runoff of water containing all material transported (control and contaminated areas) was collected and placed in mesocosms, simulating a natural condition of contamination, and then water samples were collected for the acute toxicity tests (48h; n=5), under laboratory conditions, according to the NBR 13373 standards for the species *C. silvestrii.* The results were analyzed by analysis of variance (ANOVA) followed by Dunnett's test at 5% significance level. %. The values of physical and chemical variables were similar in all treatments. However, significant differences were observed for turbidity, in this case the minimum and maximum values were 183 and 380 NTU, respectively, indicating that there is a physical effect, which reduces to 53% and 87% after 24 and 72 hours of application runoff. Regarding toxicity, no significant difference were observed between runoff control, contamination isolated and mixture. This effect can be explained by the short half-life (up to 24 hours in water) of this pesticide, as well as by the adsorption thereof to the particulate material, which promotes its non-availability, reducing the toxic effects on the biological community as mentioned by Novelli et al. (2012).

**TP254 Spatial and Temporal Concentrations of the Neonicotinoid Pesticide, Imidacloprid, in Forester Creek in Santee, CA**

*C. Batikian, San Diego State University; A. Lu, K. Watanabe, J. Pitt, R.M. Gersberg, San Diego State University / Graduate School of Public Health*

Imidacloprid, a nicotine-based systemic insecticide, is one of the highest-selling pesticides globally. It is extensively used in both agricultural and urban settings. Neonic insecticides have been most prominently linked to colony collapse disorder in honeybees and pose a significant threat to aquatic invertebrates. The USEPA established benchmarks for freshwater species exposure to imidacloprid include a value of 385 ng/L for acute exposures and 10 ng/L for chronic exposures. Within the United States, concentrations of imidacloprid detected in streams and rivers routinely exceed acute and chronic toxicity endpoints derived for freshwater invertebrates with positive correlation between percentage of urbanization and detection of imidacloprid. Forester Creek, a 16-km tributary to the San Diego River, was the study site of interest. It was chosen due to its previous wetland restoration project and its state of impairment for a variety of pollutants. Imidacloprid was detected with 100% frequency in surface water samples collected from Forester Creek with a mean concentration of 29.56 ng/L (range: 3.77 to 96.83 ng/L). Over 60% of individual samples exceeded the USEPA's chronic exposure benchmark. Temporal analysis displayed significantly ($p < 0.05$) higher levels during wet weather events (47.26 ng/L) than dry weather events (17.76 ng/L), depicting the influence of urban runoff on stream quality. Imidacloprid seemed to follow a first flush pattern with the highest levels observed on the rising portion of the hydrograph as compared to the remainder of the storm again indicating that the build-up and wash off from land surfaces during storms is a major source of this insecticide. The restored wetland/riparian section of Forester Creek did not demonstrate any significant removal of imidacloprid. The occurrence and level of imidacloprid in this urban stream contribute to the limited knowledge on imidacloprid in urban environments and will promote a better understanding of sources and effects of the neonicotinoid pesticide within the urban southern California region.

**TP255 Spatio-temporal variations of zooplankton fauna of Oluwa River, Ilaje Local Government Area, Ondo State, Nigeria**

*F.R. Olaniyan, Adeyemi College of Education Ondo / Biology; A.O. Ugwumba, University of Ibadan / Zoology; A.A. Ayoade, University of Ibadan*

The study undated the knowledge on the status of zooplankton composition of Oluwa River, Ilaje Local Government Area, Ondo State, Nigeria, as indicators of the health of the aquatic ecosystem. The major objective of the study was to provide baseline information on aspects of the biology (taxonomic composition, occurrence, distribution and abundance) of the zooplankton of Oluwa River, Ilaje Local Government Area. Zooplankton samples were collected from six sampling stations with 55µm mesh size plankton net, samples were identified and counted microscopically for eighteen months (June, 2014 – November, 2015) covering both the rainy and dry seasons. A total of thirty-eight species belonging to three groups; Rotifera (30), Copepoda(4) and Cladocera(4) were identified. Rotifera dominated the zooplankton groups, accounting for 87%. *Asplanchna brightwelli* (3.65%) was the most abundant, followed by *A. girodideguerne* (3.47%). The dry season abundance (3373 Org/L) was higher than the rainy season (3025 Org/L) Copepoda accounted for 2% of the percentage abundance of zooplankton. *Eucyclops macrurus* (3.64%) dominated; followed by *Pseudocalanus elongatus* with 3.57% in the relative abundance the rainy season abundance (475 Org/L) was higher than dry season (311 Org/L). Cladocera accounted for 11% of the percentage abundance of zooplankton. *Podon leucarti* (3.64%) dominated, followed by *Ceriodaphinia cornuta* (3.57%) in the relative abundance. The dry season abundance (489 Org/L) was higher than rainy season (476 Org/L). In conclusion, Oluwa River can be inferred to be rich in zooplankton fauna composition and therefore fairly clean and unpolluted.

**TP256 Studying elemental release of engineered nanoparticles used in outdoor painted surfaces with a focus on exposure and toxicity in aquatic models**

*K. Mittal, McGill University / Dept of Natural Resource Sciences; S. George, S. Goshal, McGill University; N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences*

Engineered nanoparticles (ENPs) are used in the manufacture of industrial and consumer products to enable or enhance specific functions towards delivery of high performance products. ENPs in outdoor painted surfaces may be released to aquatic systems with precipitation and other weathering actions though little is known about the fate, exposure and toxicity of released chemicals. The goal of this project is to use two aquatic test models (a – the fish embryo test, FET, OECD TG 236; and b – zebrafish derived cell line, ATCC CRL-2643) to characterize uptake of select elements (focus initially on titanium but also silver and silicon) from painted surfaces across temporal (0-14 days) and treatment (e.g., temperature, humidity, abrasion) gradients. A suite of outcomes will be measured in the cells (cytotoxicity, gene expression, enzyme activity) as well as in the embryos (embryo coagulation, lack of somite formation, tail non-detachment from yolk, and after 48 h the presence or absence of a heartbeat). This work is expected to increase our understanding of potential risks to aquatic organisms associated with ENPs from painted surfaces in outdoor systems.

**TP257 The fate of zinc oxide nanoparticles in aquatic mesocosms**

*S. Bae, Korea Institute of Toxicology; M. Jang, Y. Hwang, Korea Institute of Toxicology / Future Environmental Research Center*

Zinc oxide nanoparticles (ZnO NPs) are extensively used in a variety of products including sunscreens, cosmetics, plastics and ceramics, making their release into environments unavoidable, but their fate in natural environment is poorly understood. In this study, the aquatic systems were made up from natural water and sediment to mimic pond ecosystems and the fate of ZnO NPs were examined in aquatic organisms (*Semisulcospira libertine*, *Oryzias latipes* and *Hydrilla verticillata*). The mesocosms were exposed to Zn at 0.5 mg/L for 50 days. As a comparison, the same concentration of $Zn^+$ (based $ZnCl_2$) were also determined. The results showed that the concentration of $Zn^+$ and ZnO NPs quickly decreased in the water column. The aquatic plant (*Hydrilla verticillata*) and fish (*Oryzias latipes*) significantly bioaccumulated Zn. The results of $Zn^+$- and ZnO NPs- treatment were not different because the ZnO NPs at low concentration were mostly dissolved. Therefore further work is necessary to demonstrate the mesocosms study in the high concentration of ZnO NPs and dissolved Zn ion from particles.

**TP258 Threespine Stickleback as Biomonitoring Tool for Central Oregon's Iconic Rivers**

*D. Heil, A. Petersen, Oregon State University, Cascades*

Central Oregon's famous fly fisheries on the Crooked and Deschutes Rivers are at risk due to river flow draw down for agriculture: agricultural runoff, failing septic systems, and increased human population and growth. Half of the basin that runs along the Crooked River is private land used for agriculture and grazing cattle. Particularly at risk are the native trout and whitefish populations. A resource-efficient method of monitoring the health of these species is to continuously monitor the health of fish that are abundant, easy to catch, not threatened, and live as a resident in proximity to native trout and whitefish. The threespine stickleback (Gasterosteus aculeatus) is an internationally recognized model organism for ecotoxicology which resides in these rivers. We are using threespine stickleback as a wild sentinel species, by looking at pathohisotological, endorinological, ELISA, and molecular approaches to identify impacts to fish health based on location and/or river mile. Stickleback from the Deschutes River exhibit adipocyte density in the liver to be high at three of our seven sampling sites, particularly in male fish. Genotypic male fish at these sites are also producing a large amount of vitellogenin, an egg yolk protein, typically only found in females. We are currently collecting data to map the distribution and abundance of stickleback, pathohistology for disease in fish organs and cells, clutch size and embryo survival for fecundity, gas bubble disease, parasite load, at potentially impacted versus relatively pristine sites. We will discuss these data and their implications to human health and the future of the fishery in Central Oregon.

**TP259 Toxicity of Effluents with Elevated Alkalinity and Conductivity to *Pseudokirchneriella subcapitata*, *Ceriodaphnia dubia*, and *Pimephales promelas***

*N. Lynch, R. Ogle, Pacific EcoRisk*

A Discharger operating under a National Pollutant Discharge Elimination System (NPDES) permit consistently produces effluent with elevated alkalinity (>2000 mg/L) and conductivity (>8000 µS/cm) which are outside of the tolerance limits for freshwater species. The Discharger previously demonstrated effluent toxicity to the freshwater species *Pseudokirchneriella subcapitata*and *Ceriodaphnia dubia*. A third species, *Pimephales promelas*, was tested although no toxicity was observed. It was hypothesized that either the elevated alkalinity or the combination of elevated alkalinity and conductivity were the proximate causes of the observed toxicity. Several tests were performed with each of these three species to test this hypothesis, including: effluent, lab water adjusted to effluent alkalinity ('alkalinity'), and lab water adjusted to effluent alkalinity and conductivity ('alkalinity + conductivity'). The elevated alkalinity of the effluent was mimicked by adjusting synthetic lab water for each of the three species to the effluent alkalinity through the addition of sodium bicarbonate salt. The elevated conductivity of the effluent was mimicked by adjusting the synthetic lab water by the addition of 1µm filtered seawater. Dilution series tests were performed for each round of tests for each species in order produce comparative results. A single test was performed with each of the euryhaline species *Thalassiosira pseudonana* and *Hyalella azteca*, to evaluate the effectiveness of testing alternative species with a greater tolerance range for these elevated water quality parameters. Significant reductions were observed in all tests of *P. subcapitata*and *C. dubia*. However, the magnitude of toxicity decreased in the 'alkalinity + conductivity' test of *P. subcapitata*and decreased in the 'alkalinity' test of *C. dubia*. Toxicity was observed in the 'alkalinity' test of *P. promelas*only. Toxicity was also observed in both of the euryhaline species, indicating that these species would not be suitable as an alternate test species. These results suggest that elevated alkalinity and conductivity play different roles in the toxicity of each of these species, although the toxicity of this effluent cannot solely be explained by these elevated water quality parameters alone.

**TP260 Toxicological effects of tire wear particles on fathead minnow and Atlantic killifish**

*S. LaPlaca, Clemson University / Environmental Toxicology; P. van den Hurk, Clemson University / Biological Sciences*

Recent studies on the distribution of microplastics in the Charleston Harbor, SC, revealed that a large part of the microplastic particles that are found in the intertidal sediments are tire wear particles. These particles originate from the wear of tire treads on roadways, and wash into the estuary during rain events. The abundance of these particles has raised questions about potential toxicity to aquatic organisms that may ingest these particles. The synthetic rubber in car tires consist of a large variety of chemicals, which can be different between brands, but usually contains styrene-butadiene rubber, carbon black and zinc. To investigate the potential toxicity of tire wear particles, both fathead minnow and Atlantic killifish were exposed to different concentrations of tire crumb particles (63-150 um) in a 7 day exposure. Dissection of the fish revealed that particles were actually ingested and accumulated in the intestinal tract. At the highest concentration tested (6000 mg/l) we observed partial mortality in the fathead minnow, which is therefore close to the LC50. To investigate if polynuclear aromatic hydrocarbons were leaching from the particles, bile fluorescence was measured, together with potential induction of cytochrome P450-1A through the EROD assay. In addition, glutathione S-transferase was measured as a general stress parameter. Results will be discussed as comparison between the two species, with the consideration that Atlantic killifish is an estuarine species that is much more used to being exposed to high particle load in its natural environment than the fathead minnow. The results of these experiments can be used to support environmental management strategies that reduce particulate matter in road runoff from entering estuarine environments.

**TP261 USEPA's 1985 Guidelines for Deriving Aquatic Life Criteria – Update on the Status of the Guidelines Revision Process**

*M. Elias, C. Bergeron, USE EPA / Office of Water; L. Cruz, Health and Ecological Criteria Division; A. Jarvis, USEPA / Office of Water; J. Justice, USEPA; K. Gallagher, USEPA / Office of Water*

USEPA's Office of Water is in the process of revising its 1985 *Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses* (Stephan et al. 1985). The Guidelines establishes methods for the derivation of national Aquatic Life Ambient Water Quality Criteria, under Section 304(a) (l) of the Clean Water Act, that are protective of aquatic communities from both acute and chronic effects resulting from exposure to toxic chemicals. EPA is undertaking a comprehensive revision process that will result in the development of two separate methods documents: 1) a Comprehensive Guidelines Document, intended to directly update and expand on approaches presented in the 1985 Guidelines, and will describe methods that provide criteria for chemicals requiring a more detailed level of evaluation, and 2) a Streamlined Guidelines Document, which will focus on criteria development methods that are resource-conserving and can be used to develop scientifically-robust criteria, even when supporting data are more limited. A detailed Scoping Document was recently completed by the EPA, representing a first major milestone in the Guidelines revision process and a basis for subsequent revision activities. The Scoping Document: 1) provides a "roadmap" to the revision process for both the Comprehensive and Streamlined Guidelines Criteria documents, 2) details the specific objectives and approach to the ongoing revision process, and 3) discusses the specific scientific and technical topic areas that EPA has identified for detailed evaluation during the revision and their relevance and applicability to the Comprehensive and Streamlined Guidelines documents. The Scoping Document comprised the focal point of a recent Initial Consultation with EPA's Science Advisory Board, and represents another opportunity for continuing input from the scientific community during the criteria revision process. This presentation provides an overview of the key topics discussed in the completed Scoping Document, preliminary feedback provided by the Science Advisory Board during the Initial Consultation, and ongoing and planned next steps in the Guidelines revision process.

**TP262 Using a Laboratory Food Chain to Assess the Trophic Transfer of Inorganic Selenium into Secondary Consumer *Pimephales promelas***

*K. Raes, L. Doig, K. Liber, University of Saskatchewan / Toxicology Centre; D.M. Janz, University of Saskatchewan / Veterinary Biomedical Sciences; T. Lane, University of Saskatchewan; D. Green, University of Saskatchewan / Toxicology Centre; K. Bluhm, University of Saskatchewan / School of Environment and Sustainability; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre*

Concerns of environmental contamination from selenium have been propelled into the spotlight due to a growing list of disastrous examples of population level declines. The propensity for inorganic selenium species in the aquatic environment to be efficiently bioconcentrated by primary producers and transferred to higher trophic levels primarily via dietary pathways has regulatory agencies grappling for appropriate monitoring strategies. It has been suggested that due to the influence of spatial and temporal variation of the selenium cycle at any ecological site in question, local water quality criteria for selenium should be based on an assessment of site-specific properties. However, the relative importance of biogeochemistry on the uptake and transformation of selenium at the base of the aquatic food chain, and the resulting influence on trophic transfer to higher levels, remains largely unknown. The purpose of this study was to simulate an environmentally relevant aquatic food chain under strict laboratory conditions, to determine the efficiencies of inorganic selenium bioconcentration and trophic transfer from a primary producer to a primary consumer and finally to a relevant secondary consumer species. A green algae species (*Stichococcus bacillarus*) was exposed to graded aqueous selenite concentrations (0, 9, 27 and 54 ug Se/L) and uptake was quantified. The selenium-spiked alga was fed to the primary consumer *Hyalella azteca*, while maintaining the aqueous selenite concentrations. *H. azteca* became the diet for the fathead minnow (*Pimephales promelas*) in a reproductive assay, to determine compartmental distributions of selenium and maternal transfer into the offspring. This study will serve to reduce uncertainty in the trophic processes that relate dissolved selenium to bioaccumulated selenium, crucial for effective regulation for the protection of the environment.

**TP263 Variability of Trace Element Accumulation Among Invertivorous Fishes from a Coastal Plain Stream Contaminated by Coal Combustion Waste**

*D. Fletcher, Savannah River Ecology Laboratory; B.E. Lindell, A.H. Lindell, C.M. Fulghum, J.V. McArthur, University of Georgia / Savannah River Ecology Laboratory*

Invertivorous fishes are an important and diverse component of fish communities in coastal plain stream systems. Species can differ in body form, mouth position, habitat utilization, and feeding strategy. Vertical zone typically inhabited by a species can range from remaining near the water's surface, through being suspended in the water column, to living on or near the bottom. Even among bottom-dwelling species, species may inhabit swift runs, whereas others live in slow pools that represent depositional zones where higher levels of contaminants settle out. Feeding strategy can also influence the amount of sediment ingested. Such factors can influence contaminant exposure and subsequent accumulation resulting in significant variability among fish species. Coal combustion waste contamination exposes aquatic organisms to a broad array of metals and metalloids, consequently patterns of accumulation of multiple elements can be compared among species. We assessed accumulation of 19 elements in over 500 muscle samples distributed across over 25 species of invertivorous fish collected from a coastal plain stream contaminated by coal combustion waste on the Department of Energy's Savannah River Site. Trace element accumulation differed both among and within families. Overall, patterns of trace element accumulation often tended to be species specific.

**TP264 PCB Contamination in Hudson River Surface Water Resources**

*M. Byrne, US Fish and Wildlife Services / Ecological Services; K. Jahn, US Fish and Wildlife Service*

The Hudson River Natural Resource Trustees are determining the natural resource injuries from the General Electric (GE) Company's releases of hazardous substances to the Hudson River from its manufacturing facilities in Hudson Falls and Fort Edward, New York. PCBs released by GE have caused repeated and prolonged exceedances of state and federal water quality standards, contaminating surface water resources of the Hudson River for decades. Since the mid-1970s, federal and state agencies and GE have collected over 10,000 water samples from the Hudson River and have tested these samples for PCBs. Of the 8,667 Hudson River surface water samples that contained PCBs at detectable concentrations, nearly all exhibited PCB concentrations that exceed one or more regulatory standards. Water samples often contained PCBs at concentrations hundreds of times higher than relevant health-protective regulatory criteria for water, such as New York State's 0.00012 ppb regulatory standard to protect wildlife that eat fish, and New York State's 0.000001 ppb regulatory standard to protect human consumers of fish. Approximately 85 percent of samples contained PCBs, often at concentrations an order of magnitude or more above relevant state and federal regulatory criteria. The surface water resources evaluated in this assessment include the Hudson River between Hudson Falls, NY and the Battery in New York City (i.e., all waters below approximately river mile 197). This portion of the river provides habitat for biological resources, including birds, fish, mammals, invertebrates, and plants. The waters and sediments of the river support a diverse ecosystem that includes several species of rare and endangered fish, birds, amphibians, and reptiles. The health of surface water resources is critical to the survival and health of the plants and animals in the ecosystem. In addition, human uses of the river, such as recreational fishing and navigation, are closely linked to the quality of the surface water. The Hudson River Natural Resource Trustees assert these exceedances of water quality standards demonstrate that the Hudson River's surface water has been and continues to be injured.

**TP265 Studies of the physicochemical properties of Ebony River in Ebonyi State, Nigeria and on the abundance of benthic fauna during the raining season**

*A.I. Onwurah, University of Nigeria, Nsukka / Environmental Management; E. Okwuonu, C. Okoye, University of Nigeria, Nsukka / Department of Zoology and Environmental Biology*

The study of physicochemical parameters have been documented, however little may still be known on how those parameters determine the abundance and composition of benthic fauna. We investigated, from May to August, the relationship between physicochemical parameters and the abundance of some benthic fauna found in Ebonyi River. Using a scoop-net, we collected samples ranging from vertebrates and invertebrates. Four sampling stations were chosen so as to encompass as a wide range of physical conditions. The mean values of dissolved oxygen 10.56 (±0.6), alkalinity25.5mg/l (±0.3), hardness 15.3mg/l ($CaCO_3$ ±0.4) were determined. We found out that the abundance of benthos was influenced by physicochemical quality of the water, habitat, and immediate substrate of occupation, tropic condition, resource partitioning and predation. Six classes of both vertebrates and invertebrates were recorded of which the Class Insecta was dominant.Sixteengenera listed in terms of abundance and percentage i.e. *Ephemerella* 0.20(3.16), *Paraleptophilebia* 0.18(2.84), *Macrobrachium* 1.28(20.22), *Sudauonaute* 0.10(1.58), *Coenagrion* nymph 0. 73(11.53), *Aeschnua* nymph 0.20(3.16), *Gyrinus* 0.38(6.00), *Sympetrum* 0.90(14.22), *Lestes* 0.20(3.16), *Dytiscus* 0.05(0.79), *Hlobdella* 0.15(2.37), *Belostoma* 0.08(1.26), *Viviparus* 0.45(7.11), *Tilapia* 0.23(3.63), *Gomphoide* 0.50(7.90), *Chironomus* 0.70(11.06) were observed. The genera of *Coenagrion* nymph, *Sympetrum*, and *Chironomus* negatively correlated to the depth and velocity of water. However, we found a positive relationship between the water temperature and *Belostoma* genus. The negative relationships may be as a result of pollutants acquired through anthropogenic activities. However, the positive relationship between temperature and *Belostoma* genus may be as a result of essential resources e.g. food and mating season.

## Fate, Toxicology, or Risk Assessment of Materials of Interest to the Military

### WP001 Predicting Transformation Products and Physicochemical Properties of Insensitive Munition Constituents

*T.L. Torralba-Sanchez, P.G. Tratnyek, Oregon Health & Science University / School of Public Health; E. Bylaska, Pacific Northwest National Laboratory / Environmental Molecular Sciences Institute*

Traditionally, the defense industry has focused on the use of explosives such as TNT, RDX, and HMX but handling and use of these chemicals is associated with high risk of unintended detonation. Recently there has been interest in many countries, especially the United States, in using new insensitive munitions constituents (IMCs) to replace traditional explosives in the manufacturing of munitions formulations. The development and increased utilization of IMCs is creating a growing demand for information on their potential environmental impacts. To provide a complete risk assessment of IMCs, it is necessary to consider their *transformation products*. This project aims at providing a more comprehensive basis for assessing and managing the environmental risks of IMCs by extending current fate and transport models for soils and groundwater to include the products of IMCs transformation. For this, the approach includes: (*i*) determination of IMCs transformation pathways and products, (*ii*) determination of the fate determining properties of IMCs transformation products, and (*iii*) development of models that describe the fate and transport of IMCs transformation products. Presently, we are incorporating prediction library rules from existing models for expected transformation mechanisms (e.g., hydrolysis and nitro-reduction) into a novel machine-learning-based software for the estimation of IMCs transformation products along with the corresponding reaction thermodynamics. Initial results with two of the main IMCs (2,4-DNAN and NTO) show that we are able to predict the reduction products. We are also using molecular structure to estimate IMCs fate determining properties including water solubility and octanol-water partition coefficients. Preliminary estimation errors are as low as 0.5 log units from the experimentally measured values. The results of this project have practical and general applications. The practical benefit of this work will be to enable DoD training site managers to include consideration of (I)MCs transformation and products into the modeling they do for evaluation of exposure assessment scenarios, risk, remediation, etc. General applications of the results from this project will be through advancement of methods for prediction of transformation pathways, chemical properties, and reactive- transport models that could be adapted for assessing the environmental fate of other contaminant classes also of interest to the military (e.g., PFASs).

### WP002 Toxicity of the Insensitive Munition 2,4-dinitroanisole to the Earthworm *Eisenia andrei*

*M. Simini, US Army Edgewood CB Center / Environmental Toxicology; R.G. Kuperman, Edgewood Chemical Biological Center / Molecular Toxicology Branch; G.R. Lotufo, US Army ERDC / Environmental Laboratory*

The Department of Defense is developing and evaluating several insensitive munitions (munitions that will not react violently in an accident situation) for future weapon systems to replace present munitions that contain highly sensitive explosives, such as 1,3,5-trinitro-1,3,5-triazine (RDX) and 2,4,6-trinitrotoluene (TNT). Among these compounds is the insensitive munition (IM) compound 2,4-dinitroanisole (DNAN), for use as a component in several IM explosive compositions (IMXs). Data are needed to develop ecotoxicological thresholds for IM compounds that can be used to derive risk-based regulatory levels for selected key soil ecological receptors. The present study used the earthworm toxicity test with *Eisenia andrei* (ISO 16387:2004) to determine DNAN toxicity in a natural soil that has a "very high" qualitative relative bioavailability score for organic chemicals. Adult earthworms (0.3 to 0.6 g each, five per container) with fully developed clitella were randomly selected and placed in glass containers filled with 200 g of test soil. Two grams of worm food were placed in each container. A piece of clear plastic film was stretched over the top of each container and secured in place with a screw top. Pinholes were made in the plastic film to facilitate air exchange. Four replicates were prepared for each treatment level and controls. Adults were removed and counted after 28 d. Juveniles and cocoons were removed and counted after 56 d from the start of exposure. The range-finding study yielded EC20 and EC50 values of 277 mg/kg and 351 mg/kg DNAN for adult survival, respectively, and 72 and 98 mg/kg DNAN for cocoon production, respectively. Results of the range-finding assay was then used to establish the range of values used for the definitive assay. Results of the definitive assay will be reported and the toxicological endpoints will be used together with results from other invertebrate toxicity assays to develop Ecological Soil Screening Levels (Eco-SSL) for IMs that meet regulatory requirements for screening level ecological risk assessments (SLERA), plus will meet technical requirements for developing risk-based soil threshold levels for regulatory compliance in baseline ecological risk assessment (BERA).

### WP003 Ecotoxicological Effects of Insensitive Munition Compound 2,4-dinitroanisole in Soil on Potworm *Enchytraeus crypticus*

*R.G. Kuperman, Edgewood Chemical Biological Center / Molecular Toxicology Branch; M. Simini, US Army Edgewood CB Center / Environmental Toxicology; M.V. Haley, US Army Edgewood Chemical Biological Center / Molecular Toxicology Environmental; G.R. Lotufo, US Army Corps of Engineers / ERDC*

We are investigating the ecotoxicity of an insensitive munition compound (IM) 2,4-dinitroanisole (DNAN), developed for future weapons systems to replace present munitions that contain highly sensitive explosives. We designed our studies to meet regulatory requirements for developing Ecological Soil Screening Levels (Eco-SSL) for use in screening-level ecological risk assessment by adapting the standardized toxicity test for the soil invertebrate potworm *Enchytraeus crypticus* (ISO/16387:2005) using exposures in Sassafras sandy loam (SSL). This soil has a "very high" qualitative relative bioavailability score for organic chemicals in natural soils. Studies include potworm exposures to DNAN freshly amended into soil (after 24-h moisture equilibration period), or to DNAN subjected to wetting-and-drying cycles in soil in a greenhouse. This is done in order to determine toxicity benchmark values for DNAN in soil for each exposure type; including simulation of DNAN weathering-and-aging fate processes that occur in the field. Survival and reproduction data were analyzed in the preliminary study using nonlinear regression models to determine DNAN concentrations producing a specified percent effect (e.g., 50%) on the measurement endpoints. Both adult survival, and juvenile production were affected by *E. crypticus* exposure to DNAN in SSL soil based on the LC50 and EC50 nominal concentrations (mg/kg) 143 and 68, respectively, in the freshly amended treatment. These results were used to selected concentrations for the ongoing definitive toxicity tests. When completed, these studies will fill the existing data gap in current knowledge regarding the potential ecological risks of release of DNAN into soil.

### WP004 Bioaccumulation of the Insensitive Munition Compound 2,4-dinitroanisole from Soil on the Earthworm Eisenia andrei

*G.R. Lotufo, R.E. Boyd, US Army Engineer Research and Development Center / Environmental Laboratory; A. Harmon, US Army Engineer Research and Development Center; R.G. Kuperman, Edgewood Chemical Biological Center / Molecular Toxicology Branch*

We are investigating the bioaccumulation potential of an insensitive munition compound (IM) 2,4-dinitroanisole (DNAN), developed for future weapons systems to replace present munitions that contain highly sensitive explosives. We exposed the earthworm *Eisenia andrei* to Sassafras sandy loam (SSL) soil freshly spiked with sublethal concentrations of DNAN. This soil has a "very high" qualitative relative bioavailability score for organic chemicals in natural soils. Formation of 2- and 4-amino-nitroanisole (2A-4NAN and 4A-2NAN) occurred in spiked soils, but never at concentrations higher than that of DNAN. SumDNAN (sum of DNAN, 2A-4NAN, and 4A-2NAN) in soil decreased dramatically (up to 80%) during the exposure period (up to 21 d) in the presence of earthworms or plants, likely driven primarily by irreversible binding of aminated transformation products. Overall, SumDNAN body residue of earthworms remained relatively constant from 7 to 14 d, indicating relatively short time to achieve steady state. Because of the reported short half-life of DNAN in earthworms tissues, bioaccumulation factors (BAFs: ratio of the tissue to soil concentration) were determined in worms non-purged for gut contents, but corrected for the dilution effect of soil in the gut. Mean 14-d BAF were 17.6, 4.9 and 4.4 for DNAN, 2A-4NAN and 4A-2NAN, respectively. These results were used to select exposure parameters for ongoing definitive bioaccumulation tests

**WP005 Review and Synthesis of Evidence Regarding Environmental Fate and Risks Posed by Energetic Components at Underwater Munitions Sites**

*G.R. Lotufo, US Army ERDC / Environmental Laboratory; M. Ballentine, US Army Engineer Research and Development Center / Department of Marine Sciences; G.H. Rosen, SPAWAR Systems Center / Energy and Environmental Sustainability; R.D. George, SPAWAR Systems Center Pacific / Environmental Sciences*

We investigated the degree to which underwater military munitions (UWMM) pose a risk to the aquatic environment. UWMM may contain energetic compounds (EC) such as 2,4,6-trinitrotoluene (TNT) and hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX), which are among the most widely used high explosives. If UWMM becomes corroded or breaches, the fill material may leak or dissolve into the surrounding environment, potentially adversely affecting the exposed biota. In large part because of the high cost and complexity associated with sampling EC at UWMM sites, detailed and reliable information about MC in water, sediment and biota is available for only few sites and temporal and spatial uncertainties persist. Our compilation and examination of available data revealed that EC concentrations in water and sediment were largely below detection, with a few samples indicating contamination as highly localized and typically near the UWMM. To complement available site data, fate studies predicted very low concentrations of EC in the water column at UWMM sites. Available toxicity data derived for freshwater and marine fish, invertebrates and autotrophs was compiled and species sensitivity distributions were derived. Risk to biota was determined to be low at UWMM sites when measured or modeled site concentrations were compared to toxicity data.

## Using Non-Conventional Animal Models in Ecotoxicological and Genotoxicological Studies for Risk Assessment Applications

**WP006 Development of chronic water-only toxicity testing methods using mayflies**

*B.E. Roach, Alma College / Environmental Studies; A.D. Harwood, Alma College / Environmental Studies / Biology; H. Wilson, Alma College / Environmental Studies*

*Hexagenia* is a genus of burrowing mayfly that is increasingly used in sediment toxicity and bioaccumulation assays. Although this genus is primarily used in sediment bioassays, there is a desire by regulatory agencies to conduct water-only experiments with *Hexagenia*, as it reduces the complexity and additional considerations associated with a sediment test. Furthermore, the ability to compare *Hexagenia* toxicity data to that of other aquatic invertebrates would improve their utilization in water quality assessments. While acute (96 h) water-only tests are routinely conducted, there has been limited success with chronic (21 d) exposures. Therefore, to fully utilize *Hexagenia* in water quality assessments, a chronic method needs to be established. The objective of this study was to establish a method to maintain these organisms for 21 d with acceptable (< 20%) mortality. Several types of artificial burrows, as well as several substrates, feeding regimens, and light conditions were evaluated. It was determined that adding clean sea sand in conjunction with the standard glass artificial burrows yielded survival above acceptable levels. Furthermore, survival was acceptable in light and dark exposures and with two different feeding regimens. Additionally, survival rates were compared among methods in the presence of a chemical stressor (KCl) to determine if one method yields higher survival. The selected method will be validated by multiple laboratories that are interested in chronic water-only mayfly exposures, so ultimately these methods can be implemented by these agencies.

**WP007 Invertebrate Cardiotoxicity: Investigating the effect of Phenanthrene on the heart function of signal crayfish *Pacifastacus leniusculus***

*M. Ainerua, University of Benin, Benin City / Animal and Environmental Biology; R. Murphy, K. White, B. van Dongen, The University of Manchester; H.A. Shiels, University of Manchester / Faculty of Biology, Medicine and Health Sciences*

Crustaceans are regarded as excellent bio-indicators in the aquatic environment but little is known about their response to pollutants such as polyaromatic hydrocarbons (PAHs). Most recent studies focus on the impact of PAHs on marine fish and zebrafish where they have implicated phenanthrene (Phe) as the cardiotoxic PAH. This study aims to investigate the effect of Phe on the cardiac function of the invasive signal crayfish. Using a semi-static renewal method, 40 signal crayfish were exposed to 0, 0.5, 1.0, and 1.5 mg/L of Phe for fifteen days at 10°C. Heart rates (HR) were monitored every 48 hours using a non-invasive infrared sensor glued to the carapace. The crayfish were first stressed to elicit maximum HR and then allowed to recover. Prior to exposure, a baseline standard recovery curve for HR was obtained. After the exposure period, the monophasic action potential (MAP) and electrocardiogram (ECG) were recorded in a semi-isolated heart which was constantly perfused with aerated crayfish saline at 10°C. In vivo HR recovered ($P< 0.001$) to baseline in 60 mins after stress in all groups. Time-dependent analysis of HR recovery indicted that during early exposure (1-7 days) recovery of HR was significantly prolonged by up to 30 mins in the 0.5mg/L group and by 45 mins in the 1.0mg/L group resulting in a significant delay recovery time to 75%. In all cases, elevated HR returned to baseline after 60 mins. This early exposure effect in the 1.0mg/L group corresponded to a significant reduction in the detected peak-peak (N-N) interval from the smoothened HR signal. Late exposure (8-15 days) caused a significant reduction in max HR in the mid and highest concentrations thereby causing a slight downward shift of the recovery curve from the baseline. Heart rate variability (HRV) significantly increased in the 0.5mg/L and 1.5mg/L group within the last 15mins of recovery in the late exposure phase. Chronic Phe exposure (15 days) was found to affect the electrical properties of the heart by causing prolongation of action potential duration (APD90) and significantly ($P< 0.01$) elongating the corrected QT (QTc) interval. This study is consistent with findings from marine vertebrates upon exposure to PAHs. Understanding the cardiac response of crustacean heart to PAHs and physical stressors could be vital in cardiophysiological studies.

## What Matters: Global Perspectives in Advancing Science into Environmental Risk Assessment

**WP008 Ecological Risk Assessment of Microplastics and Associated Contaminants in American Samoa**

*B. Polidoro, Arizona State University; F. Asalele, American Samoa Environmental Protection Agency; T. Lewis, C. Clement, Arizona State University*

Solid waste disposal and recycling is a massive concern among Pacific Island nations. For this reason, the Marine Debris Program of the American Samoa Environmental Protection Agency has prioritized plastics monitoring, research and risk assessment within their 2016-2018 strategic objectives. We applied an ecological risk assessment framework to: 1) quantify the type and concentration of microplastics in water, sediment and biota on the island of Tutuila, American Samoa; 2) determine the type and concentration of hydrophobic organic contaminants in microplastics, waters, sediments and biota at several study sites; and 3) estimate toxicological impacts of microplastic and organic contaminant pollution on locally consumed bivalves and fishes, in order to characterize ecological risk to marine ecosystems and health risk to human populations. Although many organic contaminants and large areas of plastic debris were detected and/or recorded, microplastics were less frequently encountered in the environment and biota. Results will inform ongoing environmental regulation, educational outreach, and marine conservation efforts in American Samoa. As seafood is an important source of protein for other populations around the world, this study also provides a framework for community, scientific or regulatory agencies working in data-poor regions to conduct screening-level risk assessments using in-situ, baseline studies at the local or regional scale.

**WP009 Clear, Complete, and Justified Problem Formulations for Aquatic Life Benchmark Values: Specifying the Dimensions**

*G.W. Suter, USEPA / Office of Research and Development*

Nations that develop water quality benchmark values have relied primarily on standard data and methods. However, experience with chemicals such as Se, ammonia, and tributyltin has shown that standard methods do not adequately address some taxa, modes of exposure and effects. Development of benchmark values that are protective requires an explicit description of the issues, a problem formulation. In particular, the assessment endpoints and other dimensions should be specified for each chemical so that the necessary data will be obtained and appropriate analyses will be performed. Assessment endpoints specify the entity and attribute to be protected. In addition, the level of protection, including the magnitude of effect and the proportion affected is specified. Magnitude and proportion are included, because they are used to calculate the benchmark concentration. If uncertainty is considered in the benchmark, the proportion of the uncertainty distribution that is protected should be specified. Because effects are related to the duration of exposure and time for recovery, temporal dimensions should be specified. Clearly described exposure metrics are also needed, because the relevant exposure parameter is not always total aqueous concentration. Finally, the benchmark may be applicable to particular geographic or climatological areas, water chemistries, taxa, or habitat types. Considering and justifying all the dimensions is likely to result in protective and more easily communicated benchmarks. The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the USEPA.

**WP010 Evaluating Regional Variability in Consumer Product Consumption Data for Environmental Exposure Assessments**

*A. Pastirik, W.E. Hillwalker, SC Johnson / Global Safety Assessment & Regulatory Affairs; A. Kowalczyk, SC Johnson EurAFNE Limited / Global Safety Assessment & Regulatory Affairs; P. Mason, SC Johnson EurAFNE Limited / GSARA*

Consumer product manufacturers conduct prospective risk assessments to ensure safety of their products and to meet regulatory requirements across the globe. Exposure is based on the use of the product as designed, but priorities may differ between geographical areas. From an environmental perspective, exposure is often based on assumed down-the-drain emission. Understanding the quantity of chemical emitted is a necessary component of calculating exposure and the calculation options will be evaluated for alignment. Either annual tonnage or daily consumer consumption data can be utilized as inputs for this calculation. Annual tonnage may be assessed through internal shipping data, estimated marketing information, or external market data. Consumption rates may be estimated through consumer habit and practice surveys, or by utilizing market data from third party agencies. Additionally, opportunities and limitations of the applicability of the data sources, and implications for use will be assessed. By evaluating global sources of tonnage and consumer consumption data regional differences in product use will be identified to enhance the relevancy of the estimated emission values for use in environmental risk assessments.

**WP011 Practical Considerations for the Incorporation of Insect-Mediated Contaminant Flux into Ecological Risk Assessments**

*R.R. Otter, G. Beaubien, C. Olson, Middle Tennessee State University / Biology; D. Walters, USGS / Fort Collins Science Center; M. Mills, USEPA / National Risk Management Research Laboratory*

The approach to the management of environmental contamination has progressed as our understanding of the factors that influence the fate and effects of contaminants has evolved. Presently, most contaminated sites are managed under the widely applied risk assessment framework, which was designed not as a rigid structure but rather as a flexible process that could be modified over time and used in multiple contexts. Our scientific understanding has now advanced to the point that risk assessors can apply ecological interactions at the land-water interface, specifically insect-mediated contaminant flux, within the current framework of ecological risk assessment. In this talk, a conceptual model for insect-mediated contaminant flux will be described and its implication for the fate and transport of environmental contaminants, as they move from the aquatic ecosystem to the terrestrial environment, will be discussed. Additionally, a novel practical stepwise pathway, The Riparian Impact Test, will be introduced to help risk assessors determine if adult aquatic insects are a potential concern for the re-distribution of aquatic contaminants to the terrestrial ecosystem at specific contaminated sites.

## Environmental Pollution in Developing Economies, Policies and Population Dynamics

**WP012 Assessment of Toxicological Impact of Anthropogenic activities on Onitsha Stretch of River Niger in Southeastern Nigeria**

*A.C. Udebuani, Federal University of Technology / Department of Biotechnology; P.N. Abara, Federal University of Technology, Owerri / Department of Biological Sciences*

River Niger is one of the eight major rivers in Nigeria. This river flows through a heavily populated and commercialized city of Onitsha in Southeastern Nigeria. It also aids various agricultural, commercial, domestic activities. Waste from different anthropogenic sources and channelled into the river. However, information on toxicological and water quality status of Onitsha stretch of River Niger is scarce. Therefore, the aim of this study was to assess the toxicological impact of mixtures of chemical substances on water quality of River Niger. Water samples were collected from three sampling stations. Station 1: Niger-bridge sampling point (NBSP), Station 2: Nwangele Lake sampling point (NLSP) and Station 3: Marine Police sample points (MPSP). With a sterilized pre-labelled 2 litres' sample container. The water sample were analysed for physical and chemical parameters, heavy metal content and endocrine disrupting compounds (EDCs) in water. Heavy metal pollution index (HPI) was calculated for each parameter (Reza and Singh, 2010; Prasad and Mondal, 2008; Prasad and Kumari, 2008). Metal Pollution index (MI) was also calculated. MI value I is a threshold of warning (Mohan, et al 1996; Prasad and Kumari, 2008). Six heavy metals were obtained from Onitsha stretch of River Niger, the heavy metal pollution index obtained in the different sampling points were far above the critical values of 100 and the metal index value obtained were also higher when compared to the values reported by Lyulko et al 2001. The concentration of heavy metal obtained in the different sampling points based on the range and abundance are ranked Zn>Pb>Hg>Cd>Cr>Ni. The values obtained for heavy metal pollution index from different stations NBSP (5425), NLSP (6268) and MPSP (6420) and the metal index from the stations NBSP (428.55), NLSP (531.32) and MPSP (651.7) were far above the critical values 100 used in assessing pollution (Lyulko et al 2001). The endocrine disrupting compounds found in the study area include: polycyclic aromatic hydrocarbon, phthalates, polychlorinated dibenzo-*P*-Dioxins (PCDDs), Polychlorinated dibenzo furans (PCDFs), polybrominated diphenyl ethers (PBDEs), bisphenol A and polychlorinated biphenyl (PCBs) were obtained at varying concentrations.

**WP013 Blood Lead (Pb) Levels and Stable Isotope Ratio among Children, Infants and Mothers in Kabwe, Zambia**

*S. Nakayama, Hokkaido University; J. Yabe, The University of Zambia / Veterinary Medicine, Paraclinical Studies; H. Toyomaki, Hokkaido University / Graduate School of Veterinary Medicine; K.M. Muzandu, University of Zambia; Y.B. Yohannes, Hokkaido University / Graduate School of Veterinary Medicine; H. Nakata, Hokkaido University; Y. Ikenaka, H. Mizukawa, Hokkaido University / Graduate School of Veterinary Medicine; T. Kuritani, M. Nakagawa, Hokkaido University; M. Ishizuka, Hokkaido University / Graduate School of Veterinary Medicine*

Lead (Pb) poisoning is a serious human health concern, and one of the most common and best-recognized childhood diseases of toxic environmental origin. Lead poisoning is entirely preventable, yet it accounts for about 0.6% of the global burden of disease, with the highest burden in developing countries. Kabwe town, capital of the Zambian Central Province with a population of approximately 203,000, is among one of the most polluted places in the world. The town has a long history of lead-zinc mining, which operated for nearly 100 years without any pollution laws regulating emissions from the mine, and addressing the potential dangers of Pb contamination. Despite closure of the mine, scavenging of metal scraps from the abandoned tailings, use of lead-laced soil to make bricks, dust emanating from the mine dumps, etc… have continued to serve as a source of metal pollution. This present study investigated blood lead levels (BLLs) and stable isotope ratio in children and infant-mother pairs living around and far from the closed Pb-Zn mine in Kabwe. In total, 153 children's and 417 infants'-mothers' paired blood samples and fecal samples from infants were collected. BLLs were measured using the Lead Care II analyzer System. The result showed the prevalence of Pb poisoning in the townships near to the mining area. 93% children and 77% infants BLLs exceeded the CDC recommended level of 5mg/dL. Furthermore, ten blood samples from infants exceeded the level that can cause encephalopathy and even death (100 µg/dL). A significant correlation between BLLs of paired mothers and infants was detected. This clearly demonstrates the ability of Pb to transfer via breastfeeding. Stable isotope ratio measured with Multi-collector ICP-MS suggested that infants with high BLLs were exposed via soil and/or dust. In summary, mothers and infants with high BLLs, children who play in the soil, and young men and women who artisanally mine in the area are most susceptible to Pb and, therefore, they are at high risk. Finally, it is recommended that periodic monitoring of blood Pb in infants and children, and educating the local population should be undertaken to control the Pb blood levels in the whole population.

**WP014 Describing local air quality problems using an ontological framework: The case of Chile**

*M. Jacome, Universidad de Chile / Facultad de Ciencias Forestales y Conservación de la Naturaleza; C.A. Manzano, R. Toro, R. Morales, Universidad de Chile / Department of Chemistry; M. Leiva, Centro Ciencias Ambientales / Facultad de Ciencias / Universidad de Chile / Department of Chemistry*

Air quality problems arise from a combination of the emission of contaminants and meteorological factors that affect their transport and dispersion in the atmosphere. According to the International Agency for Research on Cancer (IARC), air quality could be responsible for the increase in mortality/morbidity rates for many chronic human diseases such as cancer. Local governments and international agencies have therefore declared air quality as a major concern for human health. Air quality regulations in Chile started in 1998 and have historically been based on the daily-average concentration of particulate matter (PM) 2.5 and 10 mm. Local environmental alerts and emergencies are declared when $PM_{2.5}$ or $PM_{10}$ measured in the state-run monitoring network are above 50 or 150 mg/m$^3$ respectively. Despite these efforts, several Chilean cities including the Santiago Metropolitan Region still have air quality problems. Additionally, other southern cities in the country are now among the most polluted in the world, due to the extensive use of wood for heating purposes; while cities in the north show recent increases in health risks associated to atmospheric pollutants although having lower-than-average PM concentrations. These facts show us that there are other important areas in the air quality management strategy that need to be developed. This study aims to explore these missing areas in Chile. The first part focused on the description of our main topic "Air Quality in Chile". This was based on the opinion of a panel of experts with different academic backgrounds (environmental scientists, public health, sociologists). The results were organized in an ontological framework to describe the topic in a systematic, systemic and logic way, by dividing it into several categories and dimensions. The objective here was to comprise all the important aspects related to the Air Quality problem in Chile in an easy-to-visualize framework. The second part of this study focused on the meta-analysis of the existing literature derived from our main topic. We classified all the articles found using our ontological framework previously developed and identified several missing areas in the current state of the research. This will help researchers and government funding institutions to prioritize their efforts to cover these missing areas. The results from this study will also be used in the analysis of the current state of the public policy in the country.

**WP015 Effect of organic and inorganic fertilizers on the bioremediation of used motor oil polluted soil**

*E.U. Ezeji, Federal University of Technology / Biotechnology; P. Ferdinand, Federal University of Technology, Owerri / Biotechnology*

Three treatments (poultry manure (PM), Nitrogen Phosphorus Potassium fertilizer (NPK), and a combination of both) were used for bioremediation of soil spiked with used motor oil to determine the potential of these treatments in enhancing biodegradation of used motor oil in soil. The degree of biodegradation of the oil was studied for a period of 4 weeks under laboratory conditions. Hydrocarbon-utilizing bacteria counts were high in all the poultry manure-amended soil ranging between $9.0\times10^6$ and $30\times10^6$CFU/g compared to unamended control soil throughout the 4 weeks of study. Oil contaminated soil amended with a combination of poultry manure and NPK fertilizer showed the highest reduction in total petroleum hydrocarbon with loss of 80% in the 4th week compared to other treatments. The results obtained demonstrated the potential of the treatments for oil bioremediation in the order: Poultry Manure + NPK > Poultry Manure > NPK.

**WP016 Effect of textile mill effluent on the growth of Zea mays**

*E.U. Ezeji, Federal University of Technology / Biotechnology; A.K. Ahamefule, Federal University of Technology, Owerri / Biotechnology*

The indiscriminate disposal of effluents from textile and chemical industries in Nigeria has become a serious problem to the environment. Most of these effluents are disposed into farmlands or directly used for irrigation purposes. This research investigated the effects of textile mill effluent on the germination and growth of Zea mays. Effluent samples were collected from a textile industry and the physicochemical parameters were analysed. Five viable maize seeds each were planted in wood shavings (sawdust) irrigated with different concentrations of textile effluent (0, 25, 50, 75 and 100 %) and observed for 15 days. Results of the physicochemical analysis showed that most of the parameters were above permissible standards. Parameters like BOD (171), COD (4208) and Nitrate (71.2) were found to be very high above the permissible limits. There was complete loss of viability at concentration 100%, while germination reduced by 75, 50 and 25% in 75, 50 and 25% textile effluent concentrations respectively. Plants growth rate was inversely proportional to concentration increase, the growth of the control significantly differed from other treatments at $p < 0.05$.

**WP017 Environmental heavy metals exposure: Impact on blood levels of heavy metals in development of cardiac diseases in ESUTH, Enugu, Nigeria**

*I.c. Ikaraoha, Imo State University, Owerri/ Chemical Pathology Unit / Dept. of Medical Laboratory Science; N.C. Mbadiwe, University of Nigeria Teaching Hospital, Enugu / Medicine; M.C. Njoku, Imo State University, Owerri / Chemical Pathology / Unit Dept of Medical Laboratory Science; C. Unadike, Imo State University, Owerri / Medical Laboratory Science; J. Dike-Ndudim, Imo State University, Owerri / Medical Microbiology Unit / Dept of Medical Laboratory Science; H. Okorie, Imo State University, Owerri / Haematology Unit / Dept of Medical Laboratory Science; C.N. Nwadike, Imo State University, Owerri / Medical Laboratory Science; O.E. Ninikanwa, Imo State University, Owerri / Nutrition and Dietetics Department; A.C. Henry, Imo State University, Owerri / Department of Medical Laboratory Science*

Substantial heavy metals exposure lingers in emerging economies such as Nigeria, where existing environmental and industrial policies/regulations are not firmly enforced. Despite indications that environmental heavy metals (Lead, Arsenic, Cadmium and Mercury) exposure may play important role in the pathogenesis of Cardiac Diseases, it has not been investigated in human population from a developing economy like Nigeria. The aim of this study is to determine the role of blood Lead, Arsenic, Cadmium and Mercury in development of cardiac diseases. Blood Mercury, Arsenic, lead and cadmium levels were determined by Atomic Absorption Spectrophotometry (AAS) in 20 male Cardiac disease patients, 20 female Cardiac disease patients, 20 male control subjects and 20 female control subjects. There was significant increases in Blood Arsenic (As), lead (Pb) and cadmium (Cd) ($p=0.000$, $p=0.000$ and $p=0.005$ respectively), but no significant difference in BMI and blood mercury ($p=0.289$ and $p=0.593$ respectively) in all Cardiac disease patients compared to controls. There was significant increases in Blood Arsenic (As), lead (Pb) and cadmium (Cd) ($p=0.001$, $p=0.002$ and $p=0.040$ respectively), but no significant difference in BMI and blood mercury ($p=0.239$ and $p=0.031$ respectively) in male Cardiac disease patients compared to male controls. There was significant increases in BMI, blood Arsenic (As), lead (Pb) and cadmium (Cd) ($p=0.02$, $p=0.008$, $p=0.017$ and $p=0.010$ respectively) in female Cardiac disease patients compared to controls. There was no significant difference in blood Mercury (Hg), Arsenic (As), lead (Pb) and Cadmium (Cd) ($p=0.208$, $p=0.517$, $p=0.155$, and $p=0.243$ respectively) in male Cardiac disease patients compared to female Cardiac disease patients. There was positive correlation of blood lead (Pb) with Cadmium (Cd) and Mercury (Hg) ($r=0.474$ $P=0.036$ and $r=0.492$ $P=0.028$) in all Cardiac disease patients, but there was no significant correlation of blood lead (Pb) with BMI and blood arsenic (As) ($r= -0.104$ $P=0.490$ and $r=0.088$ $P=0.712$ respectively). It therefore appears that increases in blood levels of Arsenic, lead and cadmium due to environmental exposure may in part contribute to the development of Cardiac diseases in this environment. Thus strict measures should be applied by the policy makers to reduce heavy metals pollution in Nigeria.

**WP018 Metal accumulation and human health risk associated with the consumption of *Oreochromis mossambicus* and *Labeo rosae* from Loskop Dam**

*J. Lebepe, University of KwaZuluNatal / School of Life Sciences; P.J. Oberholster, CSIR / Natural Resources and the Environment; I. Ncube, University of Limpopo / Biotechnology; W. Luus-Powell, University of Limpopo / Biodiversity*

Loskop Dam is known as a repository for contaminants from the entire upper Olifants catchment. Its fish populations have shown elevated metal concentrations within tissues. These concentrations have become a cause for concern as local communities rely on fish from Loskop Dam for protein supplements. This study was carried out to measure metal concentrations in *Oreochromis mossambicus* and *Labeo rosae*, and to assess edibility. Water and sediment samples were collected during winter and summer 2014 at Loskop Dam. Concurrently with water and sediment sampling, ten specimens for each specieswere collected. Metals were found to be below detection levels in the water column, however, significantly high concentrations were observed in sediment. *Labeo rosae* has shown hazard quotient of >1 for arsenic and lead, with selenium and antimony showing a hazard quotient of >0.5. For *O. mossambicus*, arsenic showed a hazard quotient of >1, with selenium and antimony showing a hazard quotient of >0.5. Lead concentration was significantly low in the muscle of *O. mossambicus*. Sediment has shown significantly higher concentration of metals as compared to fish tissues. Given that metals fixed in sediment may remobilise back into the water column, it is thus, predicted that metal concentrations in fish tissues will increase in the near future. The findings of this study serve as an alerting measure and highlight the need for recommendations and urgent interventions to reduce metal enrichment at Loskop Dam due to the serious human health implications.

**WP019 Policy management gaps, bromate content in bread and human health**

*O. Otitoju, Federal University, Wukari / Biochemistry Department; G.T. Otitoju, University of Nigeria, Nsukka / Human Nutrition and Dietetics; L.U. Iyeghe, University of Nigeria, Nsukka / Home Science, Nutrition and Dietetics*

Compliance to the existing laws in Nigeria with respect to food production by manufactures is grossly inadequate due to poor monitoring and supervision by regulatory bodies saddled with these responsibilities. Despite the fact that bakers are ban from using bromate in baking bread, there is a lot of suspicion that this compound is still being used by many bread industries. Therefore, increased risk due to consumption of bread with some levels of bromate, a possible carcinogen, by the populace may be inevitable. Hence this study estimated the levels of bromate in some bread samples from Enugu State Nigeria. A total of 30 brand of bread samples were purchased at major residential areas in Enugu Nigeria using simple random sampling by balloting without replacement three times from the same locations at intervals of two weeks. The results showed that bromate ranged from 14.93-24.28mg/kg in all the bread samples collected. These levels of bromate in the bread samples highly exceeded the United States Food and Drug Agency of 0.02 mg/kg (0.02µg/g) acceptable level in human system. Therefore, individuals who consume bread marketed in this region are at high risks of cancer, kidney damage, aural dysfunction, bronchial problems amongst others due to bio-accumulation. Furthermore, the presence of bromate in the bread samples indicates that the substance is still being utilized by bread producers despite the ban on its use by NAFDAC. The need for routine checks and sanctions of culprits is highly recommended and there is need for food safety awareness for the general public/ in the food market.

**WP020 Public health concerns of bromate in bread samples in Nigeria**

*G.T. Otitoju, University of Nigeria, Nsukka / Human Nutrition and Dietetics; O. Otitoju, Federal University, Wukari / Biochemistry Department; G.P. Arts, Wageningen University and Research / Wageningen Environmental Research (Alterra) Wageningen; L.U. Iyeghe, University of Nigeria, Nsukka / Home Science, Nutrition and Dietetics*

INTRODUCTION:Universally, bread is commonly consumed as a snack or an accompaniment to main meals. Bromate is normally utilized to make breads generally appealing to consumers. However, the International Agency for Research on Cancer (IARC) has labeled potassium bromate ($KBrO_3$) as a carcinogen. This study evaluated the total bromate in bread samples consumed in Nsukka Nigeria. METHODS 10 bread samples were purchased at regular intervals of two weeks for three times at the same locations until a total of 30 bread samples were purchased. Standard methods were used to determine the total bromate in the samples. Statistical software (SPSS version 21) was used to calculate the means and standard deviations. FINDINGS AND INTERPRETATIONS The results indicated that all the bread samples had bromate in concentrations above safe levels for human consumption (0.02mg/kg limit by US Food and Drug Agency). The bromate level of the samples ranged from 39.52-154.95mg/kg and the average concentration was 58.8mg/

kg. Such high levels of bromate are of public health concern as individuals are vulnerable to debilitating health conditions reported for bromate consumption. More so, the potential of bromate to degrade some vitamins in bread militates/opposes the global goal of combating micronutrient malnutrition. Nutrition communication and education of the general public is essential for unsuspecting vulnerable bread consumers to be aware of the safety of the foods they eat. Closure of bakeries utilizing bromate and other strict measures should also be employed. CONCLUSIONS: This research had shown that most bromate freelabelled breads in the market are not totally free and safe for human consumption. Hence, the bioaccumulation may lead to non- communicable diseases such as cancer. Key words: Public health, bromate,nutrition, bread.

**WP021 Regulatory Policies and Environmental Compromise in Developing Nation: The Nigerian Experience**

*O. Otitoju, Federal University Wukari / Biochemistry Department*

The role of various regulatory bodies in the control of food, drugs and other consumables is a vital component of safeguarding the health of the populace. However, a review of these activities shows that there is a strong negative impact on the environment. This work therefore evaluates the activities of some regulatory bodies in Nigeria between the years 2000-2017. Some of the activities examined include policy implementation and methods. Three major bodies were examined; Standard organization of Nigeria (SON), National agency for food administration and drug control (NAFDAC) and Nigerian Drug and law enforcement agency (NDLEA). Over 4000 reported cases were randomly selected from online sources and print media. The result shows that open incineration (75%) and shallow landfills (25%) are the common methods used in disposing seized commodities. These activities increased from year 2000 to 2017 but in 2017 we had the most significant amount of destroyed products both in volume and in cost of about 1.3 trillion naira. However, a total of 43 billion naira goods were either burnt or buried in the soil. Similarly, it was also observed that seized items were not sorted out neither were any laboratory analysis carried out on these items before incinerating them to ascertain the specific elements present for guided disposal action. Although the rate of boarder smuggling is on the increase, continuous open burning and burying of seized items may lead to future public health issues. We therefore conclude that regulatory bodies in developing nation should balance policies, activities and environmental safety.

**WP022 Risk assessment and estimation of total bromate in bread marketed in Enugu State, Nigeria**

*L.U. Iyeghe, University of Nigeria, Nsukka / Home Science, Nutrition and Dietetics; O. Otitoju, Federal University, Wukari / Biochemistry Department*

Compliance to the existing laws in Nigeria with respect to food production by manufactures is grossly inadequate due to poor monitoring and supervision by regulatory bodies saddled with these responsibilities. Despite the fact that bakers are ban from using bromate in baking bread, there is a lot of suspicion that this compound is still being used by many bread industries. Therefore, increased risk due to consumption of bread with some levels of bromate, a possible carcinogen, by the populace may be inevitable. Hence this study estimated the levels of bromate in some bread samples from Enugu State Nigeria. A total of 30 bread samples were purchased at major residential areas in Enugu Nigeria. Simple random sampling by balloting without replacement was used to select 10 bread samples and each sample was purchased three times from the same locations at intervals of two weeks. The results showed that bromate ranged from 14.93-24.28mg/kg in all the bread samples collected. These levels of bromate in the bread samples highly exceeded the United States Food and Drug Agency of 0.02 mg/kg (0.02µg/g) acceptable level in human system. Therefore, individuals who consume bread marketed in this region are at high risks of cancer, kidney damage, aural dysfunction, bronchial problems amongst others due to bio-accumulation. Furthermore, the presence of bromate in the bread samples indicates that the substance is still being utilized by bread producers despite the ban on its use by NAFDAC. The need for routine checks and sanctions of culprits is highly recommended and there is need for food safety awareness again for the general public in the food market.

**WP023 Risk Associated with Alternative Cleaning Method for Carrots**

*P.N. Abara, Federal University of Technology, Owerri / Department of Biological Sciences; L.A. Adjeroh, C.O. Ezea, Federal University of Technology, Owerri / Biology; A.C. Udebuani, Federal University of Technology / Department of Biotechnology*

A carrot is a nutritional root vegetable which is loaded with beta carotene, a precursor of vitamin A (Kotechal *et al*., 1998; Speizer *et al*., 1999). it is necessary to wash carrots in order to remove soil and other foreign materials before eating either raw or in processed form (Moos *et al*., 2002). It is common practice today to soak carrot in detergent solution before washing to achieve better cleaning. Studies have shown that some of the components of detergent are toxic (Jerome *et al*., 2003; HERA, 2013; Rima *et al*., 2006; Chuku *et al*., 2015). This work is therefore aimed at evaluating the residue accumulated in carrot washed with detergent. The study was divided into two stages. In the first stage, questionnaires were distributed to determine the popularity of the use of this chemical substance in washing carrot before selling to consumers. The second stage involved weighing out 2 kg of fresh carrots and soaking them in thirty one different containers. Five containers were used for increasing concentration (0.5, 1.0, 1.5, 2.0 and 2.5 g/L) of detergent 1 (DET 1) while another five containers were used for same concentrations of DET 2. The set up was allowed to soak for 20, 40 and 60 minutes. The control group was soaked in distilled water. At the end of the soaking period, the carrots were dried, grounded into powder and then analyzed using the titrimetric method described by IPAN (2005). Results obtained showed that 64.29% of the respondents agreed to the use of detergent in soaking carrot before washing, 25.14% do not use detergent in washing their carrots before selling to consumers while 10.57% were indifferent. The study also showed that the percentage anionic surfactant in carrot soaked in detergent at different time intervals before washing increased significantly ($P < 0.001$) as the concentration of detergent added and the exposure time increased. There was also a slight increase in the amount of cationic surfactant residue deposited in the carrot. On the whole, DET2 concentrated more of the cationic detergent residue than DET1. The presence of residual amount of detergent in the exposed carrot raises a public health concern as this food item is consumed daily by unsuspecting public.

**WP024 Using linear alkylbenzenes (LABs) to identify anthropogenic contributions to aquatic pollution in complex ecosystem**

*L. Xia, Jinan University / School of Environment; E. Zeng, Jinan University*

Identifying contaminants inputted to the environment and tracing anthropogenic contributions from various socio-economic activities are desirable for implementing effective management and remediation strategies. Linear alkylbenzenes (LABs) have been used as molecular markers to identify the potential anthropogenic origins for other organic pollutants with similar physiochemical properties, such as polycyclic aromatic hydrocarbons (PAHs) and polychlorinated biphenyls (PCBs). Linear alkylbenzenes are usually discharged in the environment as residues of commercial detergents and closely related to socio-economic activities during urban development. The different sources of LABs were investigated in this framework, with the use of factor decomposition method and experimental data. The cities located in the Pearl River Delta (PRD) with one of the highest population densities and fastest economic growth rates in China are mainly responsible for production and discharge of aggregated pollutants in the aquatic system. The framework identified the direct (including urban and rural domestic sewage and industrial wastewater) and indirect contaminant sources (including the external input and output and agricultural irrigation). The results showed that LABs inputted to the environment from socio-economic activities accounted for 2363.8 t/yr of Guangdong province and about 1325.3 t/yr of PRD in 2014. Domestic sector contributed 56% of the total LABs discharge, Industry and public service sectors both accounted for 41% of the total. From 2004 to 2014, LABs increased 1968 t and LABs concentration in industry sewage and consumption per capita were the main contributors to the increase of LABs. The sources of other organic pollutants will be discussed by applying the framework and comparing with the percentage of LABs. Identification of environment pollution liability is an important part of integrated pollution control in complex ecosystem. The current research provides theoretical support and a database for the formulation of policies leading to regional organic pollutant reduction and remediation of pollution.

**WP025 Effects of anthropogenic activities on physicochemical characteristics and benthic macroinvertebrates in streams in Dschang, West Region of Cameroon**

*P.B. Asanga Fai, N. Norbert, University of Dschang / Department of Animal Biology*

In Africa many water bodies are subjected to anthropogenic pressure causing perturbations in the physical, chemical and biological properties of lotic ecosystems. Benthic macroinvertebrates are tools that enable rapid bioassessment. They are easy, cost-effective, quick assessment strategies to determine ecosystem health. They have been widely used in North America and Europe. However, they are hardly used in Africa. The aim of this study was to determine the impact of anthropogenic activities on the physicochemical characteristics and on the benthic macroinvertebrate communities of streams in Dschang, West Region of Cameroon, in order to determine bioindicators of the water quality. 10 sampling stations in 3 study zones were selected which were exposed to discharges from agricultural areas (Zone A), sand exploitation (Zone B) and a slaughterhouse (Zone C) respectively. Benthic macroinvertebrates, physicochemical parameters and hydrological characteristics were evaluated on a monthly basis for one year. A total of 111 benthic macro-invertebrate species distributed in 4 phyla, 7 classes, 15 orders and 45 families were recorded. In zone B, the station permanently receiving wastewater from the sandpit (B2) was the most polluted with extremely high values of turbidity, suspended solids (SS) and colour. In zone C, the station located just downstream of the slaughterhouse (C2) was also of very poor ecological quality. Zone A was the least polluted with very low values for turbidity, SS and colour and containing the most diversified macroinvertebrate community (44 taxa). The station B2 had a considerably low abundance, low values of the Shannon-Weaver diversity index and the Piélou's equitability as well as the lowest diversity with 15 taxa. The benthic macro-fauna at C2 was also less diversified with 28 taxa. Canonical Correspondence Analysis (CAC) identified 4 organic pollutant-resistant bio-indicator taxa (*Glossiphonia* sp., Chironominae, *Chironomus* sp. and *Caenis* sp.),5 inorganic pollutant-resistant taxa (*Phaon iridipennis, Zygonyx* sp. *Orectogyrus specularis, Eurymetra* sp., *Rhagovelia* sp.) and 5 taxa (*Naucoris maculatus, Naucoris* sp., *Rhyothemis* sp., *Sympecma sp., Tetrathemis* sp.) sensitive to both organic and inorganic pollution. We have identified potential macroinvertebrate bioindicator species that have the potential for biomonitoring of lotic waters in the western highlands of Cameroon and probably similar ecosystems in tropical regions.

## Fate and Effects of Metals – Regulatory and Risk Assessment Perspective

**WP026 A study of transgenerational effects on *Daphnia exilis* exposed to copper**

*L. Martínez-Jerónimo, A. Rodríguez Miguel, Instituto Politécnico Nacional / Escuela Nacional de Ciencias Biológicas; M. Hernández, Instituto Politecnico Nacional / Zoology; F. Martínez-Jerónimo, Escuela Nacional de Ciencias Biológicas-I.P.N. / Laboratory of Experimental Hydrobiology*

Contamination of surface waters with copper is a worldwide event, usually originated by mining, agricultural, industrial, commercial, and residential activities. As a consequence, aquatic organisms are chronically exposed to sublethal concentrations of metal which can affect their fitness in different ways. One of the most sensitive groups to these stressors is the zooplankton community, particularly the cladocerans. Most ecotoxicological test guidelines are aimed to evaluate the toxic effects observed in short-time exposures or only within one generation, thus disregarding those potential detrimental effects that could appear across generations. Therefore, the objective of this study was to determine the transgenerational effects produced by copper on the American cladoceran *Daphnia exilis*, measuring demographic responses as well as responses at the macromolecular level. The acute toxic effects of copper in *D. exilis* were determined at 48 h; tested concentrations were 11, 13, 15, 17, 19 and 21 mgL$^{-1}$, at 25°C, 16:08 h photoperiod, with no food supply during assays. In the chronic toxicity studies *D. exilis* individuals were exposed to 4.9, 6.2 and 8.6 mg L$^{-1}$ copper during 21 d at 25°C, 16:08 photoperiod, feeding with 8x10$^5$ cells mL$^{-1}$ of the green microalgae *Pseudokirchneriella subcapitata*. Results demonstrated that the median lethal concentration ($LC_{50}$) was 13.45 mg L$^{-1}$. Survival and accumulated progeny in the parental generation ($F_0$) were significantly higher than those values observed in $F_1$; however, number of clutches and age to fist reproduction were not different in both generations. Concentration of lipids in *D. exilis* exposed to copper in $F_0$ and $F_1$ was not significantly higher than that measured in the control; nevertheless, carbohydrates content in $F_1$ was significantly increased respect to control. There was a decrease in the proteins content in the higher concentrations of copper in $F_0$, compared to $F_1$. Neonates size (body and total lengths, as well as body width) was significantly affected in $F_1$. In general terms, copper caused significant toxic effects on *D. exilis* mainly in the parental generation, probably because in $F_1$ the cladocerans could develop resistance mechanism to tolerate the metal (e. gr. induced synthesis of metallothioneins).

**WP027 An Evaluation of the Acute Toxicity of Lead to *Ceriodaphnia dubia* and *Hyalella azteca***

*N. Lynch, A.M. Briden, S. Vasquez, B.C. Jorgenson, Pacific EcoRisk*

The U.S. Environmental Protection Agency's (USEPA) current Ambient Water Quality Criteria (AWQC) for lead (Pb) was originally developed in 1984, and since then several studies have been performed that suggest water chemistry can have a significant impact on Pb bioavailability and toxicity to freshwater aquatic organisms. $EC_{50}$ data based upon total or nominal Pb concentrations may underestimate the toxicity of Pb. For a comparative assessment of two invertebrate species identified as being sensitive to Pb in the 2008 update of USEPA's National Effects Threshold database, *Ceriodaphnia dubia* and *Hyalella azteca* were selected for Pb toxicity testing in synthetic freshwater. Acute 48-hour testing with *C. dubia* and 96-hour testing with *H. azteca* was performed following standard USEPA methods. Test solutions were analyzed for total and dissolved Pb to facilitate determination of $EC_{50}$ values for Pb based on measured values. Results indicated solubility limits for Pb are encountered in lab water near the effect thresholds of both species and both species have comparable sensitivities to Pb, although *H. azteca* were slightly more sensitive. The Pb Biotic Ligand Model (BLM) was used to calculate predicted Pb effect thresholds, which were found to be comparable to the measured values generated in this study.

**WP028 Bioaccumulation of some selected heavy metals in the muscle tissue of cultured African catfish (*Clarias gariepinus*)**

*O. Okwuosa, Akanu Ibiam Federal Polytechnic, Uwana / Science Laboratory Technology; A.I. Onwurah, University of Nigeria, Nsukka / Environmental Management*

Often times, environmental scientists suggest that heavy metal contamination of aquatic ecosystem is related only to environment polluted by those metals. The present study was undertaken to investigate the bioaccumulation of Manganese (Mn), Cobalt (Co), Mercury (Hg), Asernic (As), Chronium (Cr) and Nickel (Ni) in the muscle tissue of Cultured African Catfish (*Clariasgariepinus*). A total of two (20) fish were used (male and female), each weighing an average of 390g and 310g respectively. They were cultured over a period of 6 months and fed with two feeds labeled A and B. At the 6th month, they were sacrificed and all the internal organs removed and then oven dried at initial temperature of $105^0$c and later adjust to $65^0$c until a constant weight was obtained. The samples were grinded and was digested with tri acid mixture ($HNO_3$:HCL: $H_2SO_4$). Digestion continued until the liquor become clear. The samples were analyzed using Dez Elmer Analyst 300 Atomic Spectroscopy (AAS). The result showed that Mn recorded 896.94±0.577mg/l; Co 78.10±0.577mg/l; and Ni, 78.725±0.578mg/l in feed 1 and Mn recorded 506.823±1.155mg/l; Co 32.499±0.577mg/l; Hg, 0.001±0.00001mg/l; As, 0.006±0.0000mg/l; Cr, 122.794±0.577mg/l. and Ni 56.180±0.578mg/l in feed 2. The result of the muscle tissue of male and female *C.gariepinus* shows the present of heavy metals at different concentrations and the highest concentration was observed in female recorded Ni (44.200±0.5774mg/l) and the lowest observed in male recorded in Cr (-0.007±0.0001mg/l). There was a significant difference (P>0.05) among male and female *C.gariepinus*. This study has proved the availability of Mn, Co, Hg, As, Cr and Ni in the muscle tissue of *C.gariepinus* and also in the water and feeds used in culture the fish. This metal concentration observed in muscle tissue, feeds and water was beyond the maximum permissible limit by FAO, FEPA and WHO for human consumption which their feed was the major source of contamination contrary to most view that bioaccumulation of heavy metals is related to environmentally polluted water. Based on these findings, it is recommended that proper quality control analysis should be carried out in the cultured fish to determine it safety.

**WP029 BLM-Based Ambient Water Quality Criteria and FMBs for Four Metals in Surface Waters of the Pajarito Plateau New Mexico**

*S.A. Tobiason, A.C. Ryan, K.E. Croteau, Windward Environmental, LLC; A.B. White, E.M. Day, S.J. Veenis, A.R. Groffman, D.J. Carlson III, Los Alamos National Laboratory*

Potential aquatic life ambient water quality criteria (AWQC) for copper (Cu), lead (Pb), zinc (Zn), and aluminum (Al) based on the biotic ligand model (BLM) were generated for 48 locations representing surface waters of the Pajarito Plateau, a relatively high altitude (~2000 m above sea level) arid region west of the Rio Grande in the vicinity of Los Alamos National Laboratory (LANL), New Mexico (NM). Most waters here are ephemeral or intermittent that flow only in response to summer monsoonal thunderstorms and spring snowmelt; the few perennial waters are sourced to springs (e.g., in Bandelier National Monument) or effluent (permitted discharges). A total of 457 BLM-based instantaneous water quality criteria (IWQC) and various spatial scales of fixed monitoring benchmarks (FMBs) were generated for each metal based on LANL sample data collected largely from 2013 through 2017, with some data back to 2005. The Cu, Pb, and Zn BLM-based acute and chronic IWQC were often substantially greater than hardness-dependent IWQC based on NM water quality standards (WQS). Consequently, observed metal concentrations exceeded the BLM-based IWQC far less frequently in comparison with NM hardness-based IWQC. Cu exceeded hardness-based acute IWQC in 36% of the samples where Cu did not exceed BLM-based IWQC, i.e., using the BLM prevents 36% false positive conclusions. Further, these results suggest that twelve waters 303(d)-listed for Cu in the LANL area should be reconsidered in light of the Cu BLM-based AWQC. Similar rates of false positive exceedances of hardness-based chronic IWQC for Cu, Pb, and Zn further warrant adoption and implementation of BLM-based AWQC in state WQS. For Al, BLM-based AWQC were also generally higher than NM hardness-based AWQC, although each basis was substantially lower than EPA 2017 proposed Al AWQC, which are computed from equations using three water quality variables (pH, DOC and hardness). Compared with EPA 2017, use of NM AWQC would result in false positive Al AWQC exceedances for 11% of the unfiltered Al samples (n=457), 41% of the samples pre-filtered using a 10-µm filter (n=149), 29% using a 1-µm filter (n=34) and 44% using a 0.45-µm filter (n=457). There is currently debate and related development regarding the most appropriate sample preparation methods for Al in natural surface water samples (i.e., acidification and filtration, to restrict aluminosilicates while representing potentially toxic dissolved and precipitated forms of Al).

**WP030 Data derived from heterogeneous stock cultures linger in criteria database**

*D. Guth, GEI Consultants, Inc. / Ecology; S. Pargee, S.P. Canton, GEI Consultants, Inc. / Ecological Division*

During a literature search to derive site-specific acute and chronic zinc criteria for a stream in Colorado a potential issue with *Ceriodaphnia* studies was identified. Two studies, Mount and Norberg (1984) and Carlson and Roush (1985), which were previously included in the derivation of zinc ambient water quality criteria were found to have sourced *Ceriodaphnia reticulata* and *Ceriodaphnia dubia* from the EPA Duluth laboratory. In 1986, a review conducted by the EPA of the *Ceriodaphnia* stock cultures at the EPA Newtown Facility and Duluth laboratories found that nearly all the *Ceriodaphnia* cultures contained not one, but two species. The cultures originally identified as *C. reticulata* cultures had *C. reticulata* and *C. dubia*. The findings of this review are not insignificant, as *Ceriodaphnia* is ubiquitous with toxicity testing and many toxicity tests occurring in the mid 1980's sourced test organisms from the Newtown Facility and/or Duluth laboratories. As a result of the widespread use of *C. dubia* and *C. reticulata* in toxicity testing, many toxicity databases used to derive ambient water quality criteria include at least one toxicity test with EPA sourced organisms during which time the cultures actually contained multiple species. During our site-specific criteria development we decided to retain the Mount and Norberg (1984) and Carlson and Roush (1985) studies in the site-specific toxicity database since this was a species identification issue and not an issue related to the toxic effects. However, toxicity data for *C. dubia* and *C. reticulata* were necessarily combined and included as *Ceriodaphnia* spp. to derive the GMAV. Retention of the toxicity test results as *Ceriodaphnia* spp. for zinc rather than two separate species resulted in our site-specific zinc FAV increasing from 86.2 to 112.3 µg/L.

**WP031 Effects of water quality in Dong Nai River on nickel toxicity to *Daphnia lumholtzi***

*T. Mai, Hanoi University of Natural Resources and Environment / Ministry of Natural Resources and Environment of the Socialist Republic of Viet Nam; L. Dieu, L. Diep, H. Phung, P. Do, K. Bui, Hanoi University of Natural Resources and Environment; T. Pham, 3FPT Software Company Limited; T. Hoang, Loyola University Chicago / Institute of Environment and Sustainability*

Vietnam is one of the fastest economic growth nations in Southeast Asia in the recent years. However, the economic growth also caused environmental consequences, especially in areas near industrial zones. Although environmental standards were recently developed, the standards are not totally relevant because of the lack of environmental toxicology data for local ecosystems. To develop a better relevant environmental standards, research on determining the toxicity of pollutants to local organisms is necessary. This study determined the influence of water quality characteristics (e.g., pH, hardness, dissolved organic carbon (DOC)) on nickel (Ni) toxicity to *Daphnia lumholtzi*. 48-h acute toxicity tests were conducted with Ni and the organisms using field collected water from Dong Nai River. Lethal effect concentrations were determined. Water quality was adjusted to represent surface water in Vietnam, ranging from very soft to hard water. In general, increasing pH, hardness, and DOC decreased Ni toxicity. When the total hardness increased from 10 to 170 mg/L as $CaCO_3$, 48-h $LC_{50}$*D. lumhotzi* increased from 87 to 1,376 µg/L, respectively. When DOC increased from 2.81 to 15.36 mg/L, 48-h $LC_{50}$ for *D. lumholtzi* increased from 96 to 216 µg/l. As the pH increased from 5 to 8.1, 48-h $LC_{50}$ for *D. lumholtzi* increased from 45 to 204 µg/L. The results will be used for setting Ni water quality standards for aquatic organisms in Vietnam.

**WP032 Reassessment of molybdenum criteria based on new toxicity data on *Tubifex tubifex***

*B. Bertelmann, GEI Consultants, Inc. / Ecology; S. Pargee, S.P. Canton, GEI Consultants, Inc. / Ecological Division*

Currently there are no United States Environmental Protection Agency (USEPA)-derived Ambient Water Quality Criteria (AWQC) for the protection of aquatic life from molybdenum. GEI developed aquatic life molybdenum criteria for the state of New Mexico using the guidelines detailed in Stephan et al. (1985), and derived an acute criterion of 7.9 mg/L and a chronic criterion of 1.9 mg/L. Using a slightly different database, similar molybdenum criteria have also been developed for the state of Nevada. In both cases, the most sensitive species in the acute database was *Tubifex tubifex*. This *Tubifex* value ultimately drove both the acute and chronic criteria values, since the chronic criterion was derived using the acute-to-chronic ratio. During a recent review of this criteria, we determined that this 1991 *Tubifex* study was questionable and not appropriate for use in molybdenum criteria development. This has also been the conclusion in recent criteria updates conducted by EPA, as toxicity of other metals were also tested in the 1991 *Tubifex* study. A new acute *Tubifex* study on molybdenum was conducted in 2017, and the $LC_{50}$ determined by this study was two orders of magnitude higher than the previous study. As would be expected, use of this updated *Tubifex* value results a significant increase in the acute and chronic molybdenum criteria values. When the chronic criterion derived for New Mexico is updated with this *Tubifex* data, it is more in line with recent calculations based on the methodology used in Europe for development of hazard concentrations. In addition, if this 1991 *Tubifex* study was used in older EPA criteria calculations for other metals that have not been recently updated, there may be other criteria that should be updated accordingly with the new *Tubifex* value.

### WP033 Risk Assessment of Inorganic Arsenic from Dietary Intake in the United States

*J. Ghossein, University of Houston, Clear Lake / Environmental Science; C.C. Zhang, University of Houston, Clear Lake*

Contaminated levels of arsenic (As) in the environment are extensively monitored due to its adverse global health effects that impact 150 million people in around 70 countries. The accurate risk assessment of arsenic, however, is challenging because arsenic is present in a mixture of inorganic and organic species in drinking water as well as various dietary products especially rice and chicken. Rice contains high levels of arsenic because it can effectively accumulate arsenic from soil, whereas chickens widely received arsenical drugs (roxarsone) for faster weight gain. Based on the environmental prevalence and major pathways to human receptor, we herein hypothesized that the main risks of arsenic exposure in the U.S. were from the consumption of chicken, rice and drinking water, and the risk levels depend on geographical locations and various ethnic groups with different diet patterns. This research was conducted to calculate risk using the most toxic inorganic arsenic (iAs) concentration data by the FDA and EPA along with the amount of rice and chicken consumed in U.S. household based on the USDA. Cancer risks for three different regions across the U.S. (i.e., the south, the mid and west regions) and four races in these regions (i.e., white, black, Hispanics and Asians) were estimated. The risk calculated using our compiled data was verified by an existing risk calculator (ATSDR calculator) created by the EPA. Results show that there is no immediate risk for U.S. residents across the three regions from rice and chicken. The risk levels of rice and chicken were in the range of $7\times10^{-5}$ to $9.9\times10^{-7}$ and $1.0\times10^{-6}$ to $1.0\times10^{-8}$, respectively. Based on dietary habits, black people were at the highest risk from chicken at $1.0\times10^{-6}$, whereas the Asian were at the highest risk from rice at $7.0\times10^{-5}$. However, our data reveal a significant threat from arsenic contaminated drinking water, particularly in the west region. The risk in the west was $3.66\times10^{-2}$, which is about 7 times higher than the risk in the south and mid regions. This risk level exceeds the risk permitted by the USEPA. This study demonstrates that even though the risk is manageable in rice and chicken, there is a potential threat to the U.S. population in certain regions with As-contaminated drinking water.

## Micro- and Nanoplastic Methods for Environment Media

### WP034 Microplastics in marine sediments: An assessment of current extraction and isolation methods

*M. Cashman, University of Rhode Island / Geosciences; K.T. Ho, USEPA / Atlantic Ecology Division; S.M. Russo, Oak Ridge Associated Universities / USEPA, Narragansett; T.B. Boving, University of Rhode Island / Department of Geosciences; R.M. Burgess, USEPA / Atlantic Ecology Division*

Despite frequent field observations of microplastics (plastic particles < 5mm in size) there is a critical knowledge gap of their fate and effects in marine and estuarine environments. Relative to fate, much of the microplastics will ultimately accumulate in marine sediments as a result of physicochemical and biological processes. Many methods exist for the extraction and isolation of microplastics from marine sediments, but major procedural differences prevent meaningful comparison among methods. These differences may result in altered recoveries of varying polymer types, sizes, and shapes present in environmental samples. The goal of this research was to conduct a systematic assessment and intercomparison of five commonly used methods for microplastic isolation and identification in representative marine sediments. Methods were selected to reflect the range of procedures in the scientific literature. Each method was reviewed for its applicability in two sediment types (sandy and silty) as well as evaluated on their ability to recover microplastics amended into sediment samples. The microplastics chosen include a range of polymers, sizes, and shapes that are commonly identified in published field surveys. The research allows for quantification of the performance of the five methods, as well as provides initial recommendations for routine microplastic monitoring procedures in marine sediments.

### WP035 How could all that stuff be in my blank!?

*K.T. Ho, M.A. Cashman, USEPA / Atlantic Ecology Division; S.M. Russo, Oak Ridge Associated Universities / USEPA, Narragansett; R.M. Burgess, USEPA / Atlantic Ecology Division*

Awareness of microplastics in our environment, and the commitment of research to understand their fate and effects is rapidly increasing. Accurate measurement of microplastics in environmental matrices is key to understanding sources, transport, sinks, and ultimately ecological effects and human exposure. As with any environmental contaminant, using and quantifying appropriate controls and blanks are essential to accurate measurements. Obtaining and maintaining quantifiable and acceptable operational blanks with microplastics often entail more and different procedures than conventional chemists and research scientists are accustomed. Clean laboratory and forensic approaches must be followed. For example, air handling systems, particularly older ones, need to be fitted with micron level filters, and the use of synthetic material (e.g., polyester clothing) which may shed fibers should be minimalized. This presentation will detail the steps taken to obtain a microplastic "clean" space in an old (40 year) marine research laboratory. Steps taken included "deep cleaning" of all horizontal surfaces in the laboratory space, application of hepa-filter air filtration, creation of a space wrapped in cotton cloth, use of a semi-enclosed water table (or working space), installation of a laminar flow hood, replacement of a synthetic microscope cover with one made of cotton, use of cotton lab coats and cotton wipe cloths, and addition of an air ionizing bar. Through these upgrades, operational blanks with only zero to two micro-sized fibers were obtained routinely.

### WP037 A novel fluorescence-extraction assay for the quantitative analysis of nanoplastics in biological tissues

*C. Liddle, Heriot Watt University / School of Life Sciences; A. Cruz-Laufer, University of Exeter / Biosciences; C. Tyler, University of Exeter / Biosciences College of Life and Environmental Sciences; T.S. Galloway, University of Exeter / Biosciences*

Globally, vast amounts of plastic are produced every year. Concern has increased regarding the impacts of plastics and its degradation products on aquatic ecosystems. Plastic debris in aquatic environments are subject to an array of abiotic processes, such as sunlight, oxidants and physical stress, which cause plastics to weather and degrade, forming micro- and nano-plastics. These degradation products need careful evaluation. Currently due to analytical limitations, the options to study the uptake and transfer of nano-plastics within biological systems is limited, and the fluorescence-methods in place have issues, e.g. background autofluorescence of tissues, which can impact the interpretation of the data, and in the worst-case scenario lead to false conclusions. Hence, it is pertinent and timely to develop accurate and repeatable methods for quantifying nanopolymers, within in vivo uptake and bioaccumulation studies. To study the transfer of nano-plastics between organisms, we developed a novel fluorometric assay, to quantitatively measure the tissue burdens of fluorescently-doped nano-polystyrene (fPNP). The performance of the assay was optimized, in terms of solvent extraction, sensitivity and reproducibility. In addition, the stability of the fluorescein-label over time and susceptibility to photobleaching was addressed. The assay was validated using several relevant model organisms:algae *Chlorella vulgaris*, water flea *Daphnia magna* and three spined stickleback *Gasterosteus aculeatus*. The optimised fluorometric-assay showed the following parameters: the limit of quantification (LOQ) for PNP measurements was 0.06-0.11µg/mg (10xStd of the control S+mean), and the effects of photo bleaching on PNP dye during the experiment was minimal. The dye-extraction from biological tissues was consistent between assays with a coefficient of variation of 2.33%(CV). Greater than 96% of the dye was extracted into the organic solvent phase (supernatant) and the recovery of fluorescence following extraction from algae-tissue homogenate was 86.65±5.2%. We also derived an optimisation protocol to assess the tissue-dependent effects of any selected species, to evaluate their effects on the quantitation of fPNP. In conclusion, we show that by solvent extracting the fluorophores prior to spectroscopic analysis, the limits of detection and recovery in the presence of tissue are sufficiently sensitive to allow the application of our assay in vitro and in vivo.

**WP038 Transcriptomic and apical effects of a polyethylene microplastic on *Daphnia magna* in a 21-day chronic study**

*J.W. Davis, K.K. Coady, The Dow Chemical Company / Toxicology and Environmental Research and Consulting*

There is growing concern regarding the fate and effects of microplastics in the environment, particularly in aquatic systems. Microplastics are generally characterized as water-insoluble, solid polymer particles that are ≤ 5 mm in size. The assessment of the potential effects of microplastics brings several challenges when designing laboratory aquatic toxicity studies. These include: selecting an appropriate test species, determining environmentally relevant concentrations of microplastics to evaluate in the study (and the units to report these concentrations), as well as setting up the test system to be able to elucidate the factors responsible for any observed effects (i.e. influence of physical effects vs. intrinsic toxicity of the microplastic, eliminating in potential effects from non-polymer additives, etc.). In our assessment, we selected to evaluate the chronic toxicity of a polyethylene microplastic to the aquatic invertebrate, *Daphnia magna* following standardized guidance. Selecting environmentally relevant concentrations required literature searches into the monitoring data, with consideration for the usefulness and accuracy of different analytical tools for microplastic measurements. Concentrations were expressed in terms of particle number per unit volume, and a natural particle control was included in the study design to be able to interpret any physical effects from intrinsic toxicity. The density, particle size, and particle number of the natural particle control was kept similar to the polyethylene test material. Additional pre-work was also required to ensure that the polyethylene test material did not contain any additives with known toxicity, and the test solutions were evaluated for their homogeneity and stability prior to the chronic study. No significant effects on *D. magna* growth, survival, or reproduction were observed in the 21-day study in comparison to control treatments. At the end of the study, mRNA was extracted from pooled *D. magna* samples and transcriptomic responses were compared among treatment groups. This was done in order to examine more subtle sub-organismal effects at environmentally relevant concentrations, and to help discern if any effects observed in the study were due to physical interactions of the particle, or rather to intrinsic toxicity of the microplastic.

**WP039 Aquatic Toxicity Endpoints for Consideration in Assessing Microplastics Exposure Associated with Subtidal Sediments**

*H. Loso, AECOM / Remediation; J. Hedgecock, Aecom Technology Corporation; E. Bergeaux, The University of Louisiana at Monroe / Toxicology; J. Wilkens, US Army Engineer Research and Development Center; A.D. McQueen, US Army ERDC / Environmental Laboratory; B. Suedel, US Army Corps of Engineers / Environmental Laboratory*

Over the past several years, there has been a growing awareness of the extent of ecological impacts from exposure to microplastics in aquatic environments. Adverse effects have been documented in various levels of the aquatic food chain, including algae (reduced photosynthesis), invertebrates such as bivalves (reduced egg production and larval yield), fish (hepatic stress and neurotoxicity), and seabirds (organ damage from co-occurring contaminants leaching from ingested plastic particles). This paper will explore the existing microplastics literature for toxicity studies on marine and freshwater species, particularly biota residing in offshore or subtidal areas. The compiled toxicity data will be evaluated and compared to the toxicity testing endpoints recommended in the Inland Testing Manual and Ocean Disposal Testing Manual developed by the USEPA and U.S. Army Corps of Engineers. The assessment will consider toxicological effects from microplastics as a physical stressor, such as blockage of feeding appendages of filter feeding benthic invertebrates and accumulation in the gastrointestinal system of fish causing starvation, as well as a chemical stressor resulting in toxicity through direct exposure to chemicals contained in the plastic particles (e.g., BPA, phthalates). Indirect (dietary) exposure to persistent, bioaccumulative, and toxic chemicals (PBTs) that adsorb to the surface of the plastic particles (e.g., polychlorinated biphenyls [PCBs], polybrominated diphenyl ethers [PBDEs], dioxins, organochlorine pesticides [OCPs]) will be evaluated relative to the previously mentioned testing manuals. The ultimate goal of the study will be to assess the appropriateness of the endpoints in the testing manuals to detect toxicity and bioaccumulation associated with microplastics in sediment. A summary of the identified data gaps in the toxicological information available for microplastics for the types of aquatic and benthic communities found in offshore and subtidal environments will also be provided.

**WP040 Considerations in Selecting Indicator Species When Estimating the Environmental Hazards of Microplastics Exposure Associated with Subtidal Sediments**

*J. Hedgecock, Aecom Technology Corporation; H. Loso, AECOM / Remediation; E. Bergeaux, The University of Louisiana at Monroe / Toxicology; J.L. Wilkens, US Army Engineer Research Development Center; A.D. McQueen, US Army ERDC / Environmental Laboratory; B. Suedel, US Army Corps of Engineers / Environmental Laboratory*

There are growing concerns related to the potential ecological risks associated with microplastics in marine waters and bottom sediments. In terms of sediment, to date, studies evaluating microplastic exposures have primarily focused on intertidal and beach marine environments; however, there are limited data focused on shallow subtidal marine environments. This paper will explore whether existing microplastics literature data for marine species are adequate to reasonably evaluate exposure to species residing in subtidal areas (e.g., kelp, eelgrass, amphipods, polychaetes, clams, sea urchins and crabs). The assessment will consider such variables as 1) the likelihood of species being exposed to microplastics via multiple exposure routes, 2) propensity of a given species to excrete microplastics, and 3) the importance of microplastics particle characteristics (e.g., size, shape, color, specific density, chemical composition) on uptake potential. In general, the ingestion pathway is considered the predominant exposure pathway, but this may not be true for some invertebrates based on particle size. For example, in one study, ingested microspheres were retained within crab body tissues for up to 14 days, while exposure to microspheres via gill transfer were retained for up to 21 days. For some species ingested microplastics can block organs by obstruction which can effect feeding. Therefore, the particle sizes of microplastics are an important consideration for indicator species selection. Other considerations include the identification of prey species more likely to accumulate microplastics and transfer them through the food chain and to what extent exposure to microplastics will change for a given type of aquatic receptor as a result of sedimentation or suspended sediments. Altered exposures from persistent organic pollutants sorbed to microplastics via ingestion by upper trophic levels, such as fish-eating birds, marine mammals, fish and invertebrates, is also important to indicator species selection. Lastly, a decision framework will be presented to guide the selection of suitable indicator species for environmental risk assessments focused on microplastics hazards associated with subtidal sediments.

### WP041 Initial survey of microplastics in bottom sediments from US waterways

*B. Suedel, US Army Corps of Engineers / Environmental Laboratory; J.L. Wilkens, US Army Engineer Research Development Center; K. Pokrzywinski, US Army Corps of Engineers / ERDC; B.N. Stevens, US Army Corps of Engineers / ERDC / Environmental Laboratory; M. Ballentine, US Army Engineer Research and Development Center / Department of Marine Sciences; J. LeMonte, US Army Corps of Engineers / ERDC; E. Beageaux, University of Louisiana, Monroe*

Microplastics are increasingly found in water bodies as a result of the widespread use and disposal of plastic products. The US Army Corps of Engineers (USACE) has observed microplastics (< 300 µm) in sediments recently collected from routinely dredged Federal navigation channels in New England. Despite rising evidence correlating the increase of microplastics to aquatic life toxicity, there is a lack of understanding of the magnitude of the problem in bottom sediments. While microplastics may be present in shoaled sediments routinely dredged by the USACE, it is currently unknown whether the presence of microplastics may be harmful to aquatic species occurring in ports, harbors, and navigation channels. The objectives of this research were to: 1) perform a literature review to better understand the current science on the quantity and quality of microplastics in bottom sediments from the US and elsewhere around the world; 2) quantify microplastic content in over 20 dredged sediment samples collected from waterways across the U.S. via particle scanning flow cytometry and Fourier Transform Infrared Spectroscopy (FTIR). The results of the literature review indicate that microplastics are ubiquitous in bottom sediments in the U.S. as well as from other countries. Additionally, the majority of studies investigated particle sizes above 300 mm, while our study addresses the methodological challenges and ecological relevance specifically of small-scale microplastics (mm). Completing these objectives will assist in improving our understanding of microplastics in bottom sediments which are of growing importance to the USACE. Understanding the nature, extent, and potential impacts of microplastics in dredged sediment will allow USACE Districts to apply this knowledge to dredging projects where microplastics are of concern.

### WP042 Temporal variability of microplastic abundance in intertidal sediments: Implications for sampling frequency

*R. Leads, College of Charleston / Biology; S. Kell, College of Charleston / Graduate Program in Marine Biology; J. Weinstein, The Citadel, Military College of South Carolina / Biology*

The occurrence, distribution, and composition of microplastics (< 5 mm) are well documented on shorelines worldwide. However, high variability in microplastic abundance is often observed within and among studies. The majority of microplastic surveys to date consist of single sampling events that do not consider temporal variability as a potential confounding factor in the interpretation of their results. Therefore, these microplastic surveys may not accurately represent microplastic abundance, distribution, and composition. Here, we investigate the small-scale temporal and spatial variability in the abundance and distribution of microplastics in the intertidal zone of a sandy beach in the Charleston Harbor estuary, South Carolina. Intertidal sediment was collected from the low intertidal zone (n=3) and high intertidal zone (n=3) at low tide over 17 days (12 sampling events; total n=72). Over the course of the study, microplastic abundance ranged from 44-912 microplastics/$m^2$. Microplastic abundance differed significantly among sampling events (p=0.00025). In addition, microplastic abundance differed significantly among some consecutive tidal cycles (p=0.007). Over the course of the study, microplastic abundance did not differ significantly between the low intertidal zone and the high intertidal zone (p=0.76). These results indicate that there is significant temporal variability of microplastic abundance in intertidal sediments of the Charleston Harbor estuary. Accordingly, future microplastic surveys need to include a temporal component in their study design to more accurately quantify microplastic abundance.

### WP043 Microplastics in a suburban stream

*H.F. Libelo, J.F. Gallagher, Arlington Virginia Public Schools*

Sources of microplastic particles to rivers are not understood very well. The concentration of microparticles in the Chesapeake Bay and some of its tributaries have been measured, but their sources have not been identified. To find out if the surface runoff and the WWPT discharge are sources Four Mile Run, a small suburban stream that empties into the Potomac river near Washington, DC, and the discharge from the Arlington Virginia Water Pollution Control Plant and were sampled. Particles were collected by securing 25 sq. cm of 0.3 mm polyester mesh screen to the end of a 500 mL funnel and pouring 10L of water through. Three samples were collected at each of four locations in the stream and the WWTP discharge. The mesh with particles was removed from the funnel, labeled, wrapped in aluminum foil and stored in zip lock bags for transport out of the field. Each sample was placed a glass petri dish and immersed in 35% hydrogen peroxide for 24 to 48 hours to remove natural organic material. The digested samples were examined under 40x magnification, the particles counted, and size and appearance recorded. Microplastic particles were found in all samples, at average concentrations of 0.30-0.55 particle per liter. Most appeared to be polyester fibers. Others appear to be rounded polyethylene other polymer, based on visual inspection. Based on the average stream flow rate of 50 million liters per day Four Mile Run delivers 25 million microparticles per day to the Potomac River. The sewage treatment plant adds 30-40 million particles per day. These data suggest that the stream and WWTP are significant contributors to microparticles to the Potomac River.

### WP044 Rain Gardens Mitigate Microplastics Entering Aquatic Habitats

*D. Lin, San Francisco Estuary Institute / Department of Civil and Environmental Engineering; A. Gilbreath, San Francisco Estuary Institute / Watershed Program; L. Werbowski, University of Toronto / Department of Ecology and Evolutionary Biolog; J.A. Hunt, I. Shimabuku, San Francisco Estuary Institute; X. Zhu, J. Grbic, University of Toronto / Department of Ecology and Evolutionary Biology; M.D. Sedlak, R. Sutton, A. Richey, San Francisco Estuary Institute; C.M. Rochman, University of Toronto*

Urban runoff is suspected to be an important pathway for microplastic to enter San Francisco Bay, but there are very few studies that report microplastic concentrations in stormwater. A bioretention rain garden draining an urban watershed area composed of roads with heavy car and foot traffic and high density residential and commercial land use was monitored through three separate storm events in 2017. Composite influent and effluent samples were collected through the hydrograph of the storm. Particle samples were separated by density separation, individually enumerated and categorized under a dissecting microscope, polymer types were identified by Raman spectroscopy. Results include particle concentrations in stormwater, as well as the breakdown of particle concentrations by particle morphology and polymer type. Comparison of influent and effluent concentrations show high particle removal efficiencies. Additionally, field blanks collected provided quality assurance for the data. Due to the limited amount of data on microplastic in stormwater, this information is a significant contribution to the field of microplastic research.

**WP045 Influence of particle size on prospectively modeled environmental concentrations of microplastics in the Sandusky River watershed**

*C.M. Holmes, Waterborne Environmental, Inc.; A. Koelmans, Wageningen University / Aquatic Ecology and Water Quality Management; S. Dyer, LeTourneau University*

The presence of nano- and microplastics (MPs; particles < 5 mm) in the aquatic environment is a topic of increasing discussion and research. Although measurement and monitoring data are indispensable, there is a need to prospectively estimate concentrations to enable forward-looking assessments and to guide analysis of retrospective ecological analyses. For traditional chemicals, fate and exposure models have been proven to be very helpful and are widely used. However, to date few models exist that simulate the transport and fate of MPs in freshwater systems. This presentation presents simulations of the transport and fate of various-sized MPs emitted from wastewater treatment plants into freshwater riverine systems, and tracks concentrations moving downstream from headwater into Lake Erie. We linked the NanoDUFLOW model (a detailed MP aggregation-sedimentation model integrated in a hydrological and particle transport model) with iSTREEM® (developed to estimate chemical concentration distributions for all rivers receiving WWTP discharges in the US) for a range of particle sizes. This combines the mechanistic realism of NanoDUFLOW, accounting for formation and settling of heteroaggregates, with the US well-established iSTREEM implementation. Depth dependent in-stream first order removal rate constants simulated with NanoDUFLOW were combined with standard iSTREEM output which simulated the emission, transport and water column concentrations of different MP sizes. We modeled floating as well as non-buoyant MP, for sizes ranging from 100 nm to 1000 µm. We also modeled a combined mixture of particle sizes based on effluent measurements from Mason et al (2016). Simulations were spatially explicit with MP concentrations being modeled for the Sandusky River watershed in Ohio containing over 300 miles of river downstream of 20 WWTPs. Modelling results show the effects of population density, MP size and environmental conditions on riverine concentrations and export to Lake Erie. Buoyant as well as the smallest non-buoyant MP fractions can be transported over long distances, reaching receiving waters such as the Great Lakes. In contrast, larger non-buoyant MPs settle more locally in the vicinity of the WWTPs.

## Incorporation of Sustainability into Undergraduate Curricula in Science and Engineering

**WP046 Community Based Learning in Teaching Sustainability Engineering**

*A. Hicks, University of Wisconsin, Madison / Civil and Environmental Engineering*

The three paradigm of sustainability: environmental, economic, and societal, are challenging for students to fully grasp and apply in an engineering context. Community based learning (CBL) is an approach to contextualize the paradigm, and to allow students to evaluate the sustainability of a particular system. Utilizing CBL also served as an avenue for students to better understand the uncertainties present in real-world engineering situations, and to engage with stakeholders in the broader community. CBL was introduced to the "Environmental Sustainability Engineering" course at the University of Wisconsin-Madison in the Fall 2016 semester (and was continued in the Fall 2017 and 2018 semesters) . Students chose one of three community based projects, including a potential solar panel installation for a low income housing community, salting practice changes as a method of reducing chloride run off to a local lake, and the egg production for a farm to table restaurant. Students evaluated the systems through the lens of industrial ecology, and utilizing the three paradigm to make their recommendations. Within this, tools such as cost/benefit analysis, payback period, economic input output life cycle assessment, and societal changes were utilized to by the students. The students were assessed at the beginning and end of the semester to gauge their knowledge of topics to be covered in the course, and again at the end of the semester. These are also compared to the same knowledge probe which was utilized the previous time the course was offered without the CBL component, to better understand knowledge gains, and the influence of incorporating a CBL component to the course. The results of the knowledge probe will be presented, along with challenges encountered (and how to overcome them) with the CBL aspect of the course.

**WP047 Leveraging scientific studies popularized by social and news media outlets to engage students of various educational backgrounds**

*E. Medlock Kakaley, USEPA / UNC Cooperative / Dept of Biological Sciences / Environmental and Molecular Toxicology Program; I. Jaspers, Curriculum in Toxicology / University of North Carolina at Chapel Hill*

Everyday we are bombarded with half-true sound bites and inflammatory news statements about the world we live in, more specifically the latest scientific findings. In this introductory toxicology course students read, discussed and presented recent news stories and corresponding cited peer-reviewed literature. Through experiential learning, students interpreted the true meaning of scientific findings and acquired applicable presentation and peer-review skills as well as foundational toxicology concepts. Students were polled pre- and post- semester with an online survey tool for self-assessed knowledge of toxicology and expected/actual acquired skills. All assigned materials for each of five course modules were provided electronically through the university education platform. Introductory information was presented by local field experts for 4 of 5 modules. Students presented their assessment of scientific interpretations made by both researchers and reporters/journalists through a Powerpoint® presentations or in a discussion-based format. Fundamentals were covered on an as-needed basis during class discussion. The academic level and program was highly mixed in the small class size of 6, 5 of which had never enrolled in a toxicology course prior to Spring 2018. However, the range, recent media coverage, and expert-led introduction of each module made topics more accessible, allowing for ample participation from all students. In fact, the range of self-identified "knowledge of field" and "knowledge of current events in the field" increased from "little prior knowledge" to "somewhat knowledgeable" in the pre-course survey to "somewhat knowledgeable" to "very knowledgeable" after course completion. Students over-whelmingly reported favoring the teaching modules, and despite reports of instructor's sound knowledge of the field and willingness to discuss fundamentals some reported lack of intentional direction in course discussion. Ultimately, 1 of 2 admitted/undecided students chose the toxicology track of study. Therefore, this course will again will be offered in Fall 2018 to all students with interest in the field of study. Module introductions will be instructor led, or instructor will more clearly guide content of expert-led introductions, to better emphasize field fundamentals. Thus allowing ample application of fundamentals during student-led news/article assessment and creating more intentionality during discussion.

**WP048 Planetary boundaries in STEM education towards a sustainable future: Integrating sustainability into the undergraduate curriculum**

*J. Blatti, Pasadena City College / Chemistry*

This talk will discuss various approaches to incorporate sustainability into the undergraduate curriculum, including undergraduate research in sustainability, curriculum development in sustainability, the development of interdisciplinary, cutting edge labs that emphasize the principles of Green Chemistry, and sustainability outreach and education to underrepresented populations, which includes a campaign to promote diversity in the STEM workforce. Under the theme of Sustainability, topics such as renewable energy, climate change, biopolymers and sustainable materials are explored. Research in these areas is translated to outreach lessons to bring awareness of sustainability and Planetary Boundaries (PB) to underrepresented communities and to inspire the next generation of scientists to use their skills to solve the environmental challenges of our time. As part of the Sustainability Science and Engineering course in the Winter of 2017 at Caltech's Resnick Sustainability Institute, we evolved a project to use the framework of PB as a platform to discuss how each aspect of sustainability science relates to students' lives, as oftentimes students do not see the connection between these big ideas and their actual lives. We use hands-on laboratory experiments, such as the synthesis of biodiesel from algae oil, making paints from sustainable materials, and DNA nanotechnology as a way to drive in depth discussion of these topics. Although there is a strong desire from sustainability educators to disseminate lessons and make a broad impact, efforts in the area of sustainability education remain localized. Promoting diversity in the STEM workforce is an opportunity to make a broad impact in sustainability education and sustainability science. Lastly, this talk will discuss ways to emphasize creative problem solving in science as part of the scientific method, which includes art-science intersections as a means for students to develop critical thinking skills so that they can think 'outside of the box' and solve imminent environmental challenges of our time.

## Integrating Cooperative Federalism into Environmental Research and Assessments

### WP049 State-Federal Research Collaboration through the National Estuary Program

*G. Cicchetti, USEPA / Atlantic Ecology Division / National Health / Environmental Effects Research Laboratory / Office of Research and Development; W.S. Fisher, USEPA / Office of Research and Development / National Health and Environmental Effects Research Laboratory*

Estuaries are among the most productive ecosystems in the world, providing unique habitat for freshwater and marine species as well as valuable social and economic benefits. The wealth of ecosystem goods and services from estuaries has led to growth and development of human communities in adjacent areas and a concomitant increase in human activities that degrade habitat and water quality. Management for sustainable estuaries necessarily balances environmental concerns with community social and economic values. The non-regulatory National Estuary Program (NEP), instituted by the Clean Water Act and supported through EPA's Office of Water, provides opportunities for stakeholders to manage 'nationally significant' estuaries. Each of the 28 estuaries currently in the NEP engages a diverse community of stakeholders, ensuring that local economic and social values are incorporated into estuary management plans. The real-world decisions faced by NEP managers provide fertile ground for applied research on estuarine water quality and aquatic life resources. The coastal ecology Divisions of EPA's Office of Research and Development, National Health and Environmental Effects Research Laboratory, are engaged in water quality and aquatic life research and have worked closely with NEP managers on multiple projects across the United States. Several of these collaborative efforts are highlighted with the intent of fostering even greater focus and participation.

### WP050 TechTracker Tool Documents Cooperative Federalism at the USEPA

*B.T. Walton, USEPA / NHEERL; E.T. Lavoie, USEPA / Office of Pollution Prevention and Toxics; S. Burden, W.J. Cybulski, USEPA / Office of Science Policy; S.J. Paul, USEPA; K.A. Saterson, USEPA / NHEERL; G. Stroup, USEPA / NERL; L. Riddick, USEPA; S. Stohs, USEPA / NCEA*

With publication of the FY 2018-2022 EPA Strategic Plan, the U.S. Environmental Protection Agency (USEPA) endorsed cooperative federalism to improve environmental protection through shared governance and enhanced collaboration by the USEPA with state, tribal, local, and federal partners. This evolving reliance on collaboration across government at all levels is supported by the EPA Office of Research and Development (ORD). Increasingly, ORD is seeking input from USEPA partners and stakeholders to identify pressing environmental problems and provide support for science-based solutions. Herein, we report on the topics and demand for ORD scientific and technical expertise based on data from TechTracker, a new tool developed to document the regulatory, programmatic, and scientific support that ORD provides to partners and stakeholders. The tool documents the hours, topics, and users of ORD's environmental expertise. Analysis of more than 34,000 hours of consultations recorded by ORD scientists since the beginning of 2018 fiscal year shows the majority of the more than 2500 requests came from within the agency; that is, from the ten USEPA regions, the program offices and intramural research Laboratories and Centers. All 50 states, plus U.S. territories, >50 federal agencies, a dozen countries, 26 tribes, 54 cities and communities accounted for an additional 25% of the requests. Topics generating the most requests aligned well with the core USEPA mission—to protect human health and the environment. ORD respondents most frequently chose, in order, (1) ecology/environment, (2) human health, and (3) chemicals as most descriptive of their queries. Scientists were usually asked (55% of requests) to provide technical information or to review technical documents. We also tracked interest in topics of hazard characterization, microbiology, regulation and other policy actions. Queries were infrequently categorized as sustainability, social sciences, or economics/benefit analysis. We designed TechTracker as an internal tool to understand demand for technical expertise among our partners and stakeholders as well as to foresee potential needs for expertise and areas of emerging interest. Results to date indicate the importance of EPA outreach to partners and stakeholders as cooperative federalism rises on the federal agenda.

### WP051 Application of the Ecotoxicology Knowledgebase (ECOTOX) to support environmental research and risk assessment

*J.H. Olker, USEPA / ORD / NHEERL / Mid-Continent Ecology Division; C. LaLone, USEPA / Mid-Continent Ecology Division; C. Elonen, USEPA / ORD / NHEERL; S. Erickson, A. Pilli, A. Pilli, General Dynamics Information Technology; D.J. Hoff, USEPA / ORD / Mid-Continent Ecology Division*

The ECOTOX Knowledgebase (http://cfpub.epa.gov/ecotox/) is a nationally and internationally recognized source of curated single-chemical toxicity data for aquatic life, terrestrial plants, and wildlife. This publicly available database currently includes data on more than 11,000 chemicals from over 47,000 references. ECOTOX data are used for all ecological risk assessments supporting pesticide registrations and re-registrations, all ambient water quality criteria for chemicals published since 1985, site-specific water quality criteria (by EPA Regions, States, and Tribes), and assessments used in emergency response. A significantly enhanced interface (v5.0) of the ECOTOX Knowledgebase was released in 2018. Advances include the integration of improved and computationally automated literature search strategies for data curation, and inclusion of more mechanistic (e.g., genetic, enzymatic) and pathway-based (e.g., hormonal, cellular) data to better align with the evolution of toxicity testing. This newly released ECOTOX user interface has enhanced functionality for searching and exploring data, with interactive data visualization capabilities. Further, links to other EPA tools (e.g., CompTox Chemistry Dashboard) and databases were integrated, laying the foundation for future interoperability. Presented here are three case studies demonstrating how ECOTOX v5.0 has improved to support environmental research and risk assessment. The case studies focus on: 1) linking detections and concentrations of environmental contaminants to effects data; 2) identifying empirical data to support and expand the development of adverse outcome pathways; and 3) gathering data for development of toxicity reference values. In these examples, the new ECOTOX *Explore* options were used to evaluate the scope of data availability, observe potential trends across chemicals or biological species, and develop testable hypotheses, thus demonstrating how improved features allow for rapid acquisition and analysis with the most relevant available toxicity data. With the new and improved ECOTOX platform, researchers and risk assessors can explore, visualize, identify, and download curated toxicity effects data that best match exposure scenarios, species of interest, and most appropriate assessment and measurement endpoints for developing or addressing focused research questions and decision-making. This abstract does not necessarily reflect USEPA policy.

**WP052 Environmental Toxicology Data Quality Evaluation, Extraction and Data Integration Under TSCA**

*T. Wright, K. Eisenreich, USEPA / Office of Pollution Prevention and Toxics; C. Elonen, USEPA / ORD / NHEERL; A.A. Kennedy, USEPA / Office of Pollution Prevention and Toxics; K. Koehrn, A. Nguyen, USEPA / Office of Chemical Safety and Pollution Prevention*

In 2016, the Frank R. Lautenberg Chemical Safety for the 21st Century Act amended the Toxic Substances Control Act (TSCA), the nation's primary chemicals management law. To meet the scientific standards under TSCA, the Office of Pollution Prevention and Toxics (OPPT) is conducting systematic review to evaluate the ecotoxicology data for the first 10 chemicals undergoing risk evaluation. The new process, already in progress, included a first step in which a search strategy was developed and used to gather environmental toxicity information. The titles and abstracts for citations identified in the search were screened using ECOTOXicology knowledgebase (ECOTOX) criteria to parse them into "on-topic" and "off-topic" bins. The "on-topic" references were then subject to a full-text screening using additional, more specific ECOTOX criteria to evaluate study relevance and determine which citations should move to the next step, data extraction. Information gathered from authoritative grey literature also underwent the full-text screen and data extraction steps. EPA developed data quality evaluation (DQE) criteria under TSCA, based on a combination of EPA's ECOTOX criteria and the Criteria for Reporting and Evaluating ecotoxicity Data (CRED). EPA will evaluate each study using the DQE criteria to determine overall study confidence. The data resulting from this systematic review analysis will serve as the basis for developing a hazard characterization and will be integrated into the risk evaluation for each of the 10 chemicals.

## In Situ Treatment of Contaminated Sediments – What Are the Remaining Barriers?

**WP053 In situ activated carbon (AC) amendment to limit bio-uptake from PCB contaminated sediment – A mesocosm study with three organisms**

*A. Wang, Northeastern University / Civil & Environmental Engineering; P.T. Gidley, USACE / ERDC / EL; A.J. Kennedy, US Army Engineer Research and Development Center / Environmental Laboratory; A. Wooley, G.R. Lotufo, US Army Corps of Engineers / ERDC; C.E. Ruiz, N. Melby, US Army Engineer Research and Development Center; S.N. Schmidt, Technical University of Denmark / Atlantic Ecology Division; P. Mayer, Technical University of Denmark / Department of Environmental Engineering; U. Ghosh, University of Maryland Baltimore County / Chemical, Biochemical, and Environmental Engineering; T. Bridges, US Army Engineer Research and Development Center; L.A. Fernandez, Northeastern University*

In situ AC amendment (4.3% by dry weight homogenized with sediment) was investigated in an experimental mesocosm containing PCB contaminated sediment from New Bedford Harbor (New Bedford, MA, USA). AC was applied by homogenization with sediment prior to the start of the experiment. This may be feasible in the field where dredging is performed. In other cases, AC would be applied as a cap (secured with a sand or armor layer to prevent degradation) and would become homogenized over time due to bioturbation and other processes. Experimental conditions are likely representative of field conditions 10 ± 5 years after application. As this is not a practical experimental time frame, homogenization of AC and sediment allows simulation of long term conditions. Efficacy of AC amendment was evaluated by measuring freely dissolved porewater concentrations ($C_{free}$) and lipid normalized tissue concentrations ($C_{lipid}$), compared to unamended, control mesocosms. Three organisms of varying levels of sediment interaction were tested. $C_{free}$ were deduced by low density polyethylene (LDPE) passive sampling. $C_{lipid}$ were deduced by homogenization and extraction of organism tissues. Overall, decreases in toxicity equivalents were achieved with AC amendment. PCB congeners ranging from 2 to 9 chlorines (Cl) were detected in organism tissue and 2 to 8 Cl in sediment porewater. Reductions in $C_{lipid}$ were observed with AC amendment for congeners up to 6 Cl and in $C_{free}$ up to 7 Cl. Increases in $C_{lipid}$ were observed across all congeners of 7 – 9 Cl and minor increases in $C_{free}$ for one 6 Cl and two 8 Cl congeners indicating mobilization of larger congeners in the presence of the AC amendment. In order to determine whether overall toxicity equivalents were decreased by AC amendment, analysis of the dioxin-like (co-planar) congeners was performed. The sums of $C_{lipid}$ and $C_{free}$ for the dioxin-like PCBs decreased by an order of magnitude from 3550 to 361 µg PCB/kg lipid and from 4.73 to 0.121 ng PCB/$L_{Water}$ respectively, indicating a decrease in expected toxicity in AC amended sediments even though increases in the $C_{lipid}$ and $C_{free}$ of some individual congeners occurred.

**WP054 Novel In-situ Toxicity Assessment of Sediment Cover Effectiveness in Deep Water**

*G. Burton, University of Michigan / School for Environment and Sustainability; M. Hudson, University of Michigan / School of Natural Resources and Environment; K. Thiamkeelakul, University of Michigan School for Environment and Sustainability; S. Nedrich, University of Michigan; E.C. Cervi, University of Michigan / SEAS; A. Rentschler, University of Michigan; S.S. Brown, The Dow Chemical Company / Environmental Remediation and Restoration*

A former mining site has been the subject of intensive restoration for the past few years, with significant focus on disconnecting mine spoils from groundwater and managing the quantity and quality of runoff. An investigation was conducted to compare the efficacy of selected cover materials for decreasing Zn dissolution during periods when the hypolimnion is anoxic and acidic (pH=5.5). Cover materials were selected based on results from laboratory batch testing and included AquaBlok, limestone, and limestone + bonechar. Experimental field tests implemented novel methodologies, using Limnocorrals (LC) to isolate water columns above various cover treatments, simulating lake-mesocosms. Simultaneous in-situ and ex-situ toxicity tests were conducted using *Daphnia magna*, *Hyalella azteca*, and *Chironomus dilutus*. Test organisms were protected from temperature shock by pre-acclimating over 24 hrs and then deploying the test chambers in a Toxicity Assessment Container System (TACS), which protected the organisms from warm surface waters until reaching the bottom sediments and colder water. Test organisms were exposed to surficial sediments and overlying water in the reference (no cover) LC and in the two LCs containing surficial sediments plus cover materials. Ex-situ testing was conducted in waters and/or sediment cores collected from the bottom of each LC, and these tests were done at the same temperature as the in-situ TACS exposures (15 to 19 C, depending on deployment period). Laboratory tests involved a series of acute toxicity tests and water chemistry sampling conducted in core microcosms created from site-collected sediment. Results from in-situ testing demonstrated the usefulness of the TACS and provided similar results to the ex-situ testing. Overall, there were no differences in biological responses/endpoints between treatments involving sediment cover materials, and this was true in both the field and laboratory tests. This was likely due to the fact that dissolved Zn concentrations in the surface water were below-threshold levels in all treatments. All treatments (AquaBlok, limestone, and limestone + bonechar) successfully reduced Zn release from the sediment, although some may be less effective under certain hydrologic conditions. Results provided for more effective decision-making, with reduced uncertainty, than standard laboratory and chemistry-only approaches. Follow up testing will examine zinc release delay via dissolution rates.

**WP055 PCB Tissue Concentrations and Benthic Community Impacts at a Carbon Amendment Pilot Study in the Intertidal and Subtidal Zone of San Francisco Bay**

*R. Zajac, T. Himmer, CH2M; S. Clark, Pacific EcoRisk; A. Salter-Blanc, J. Eby, CH2M; S. Ohannessian, NAVFAC; C.A. Irvine, RBI / Ecosystem Services*

Historical site activities at the Hunters Point Naval Shipyard (HPNS) and other off-base locations in South San Francisco Bay resulted in the release of chemicals, including PCBs, to offshore sediments. To inform remedy selection at HPNS, activated carbon (AC) amendments alternatives were evaluated in a pilot treatability study. Two 0.4 acre plots extending from the intertidal to the subtidal zone treated with either AquaGate + PAC™ or SediMite™ were assessed for the potential to reduce ecological risks associated with PCB-contaminated sediment. Previous treatability studies indicated that AC may be effective at reducing the bioavailability of PCBs to the bent-nose clams (*M. nasuta*) in shallow intertidal sediments when aided by mechanical mixing. This study assessed the effectiveness of AC placements without mechanical mixing in deeper water that is more representative of conditions where full-scale remediation is expected. Tissue bioaccumulation, benthic invertebrate community composition, and chemical analyses were measured as indicators of remedy effectiveness. Comparisons were made between baseline, reference and post-amendment conditions (8, 14, 20, and 26 months post-placement). PCB tissue concentrations in *Macoma* sp. were measured in situ and *ex situ* (bench-top) after 28-day exposures. Developing field exposure chambers that allowed sediments to infiltrate the chambers and expose clams upon deployment and retrieve the sediment and exposed organisms for chemical analyses was a challenge. Modifying a chamber design used in previous studies by Luthy et al. (2009) proved successful. Test organisms were another challenge. Tissue bioaccumulation was planned to be conducted with *M. nasuta* but instead, initial measurements were made with *M. secta* (white sand clam) collected at a nearby reference location where *M. nasuta* had been previously found. The species have a similar appearance and life histories but *M. secta* had low survival in the field (< 20%), lab exposures (< 60%), and lab controls (10%). Additional field pilot testing led to the use *M. nasuta* from a supplier for post-amendment monitoring. PCB tissue concentrations were reduced by approximately 90% in Plot 1 and 80% in Plot 2 amendment areas after 26-months post-placement. Benthic invertebrate communities in test plots showed greater diversity at 26-months post placement compared to other monitoring events, indicating that the AC treatments had no long-term negative impacts on community health.

## Environment Exposure to Microplastics and Affiliated Toxic Chemicals

**WP056 A novel technique to qualify and quantify fine microplastics in surface water by coagulation and μFTIR microscopy**

*Y. Kameda, N. Yamada, Chiba Institute of Technology / Creative Engineering*

The occurrence of Microplastics (MPs) is of great concern in aquatic environment, especially ocean. Many current studies evaluate MPs ranged from 100 μm to 5 mm. However, MPs used in personal care products and other industrial processes are reported to be smaller according to previous reports. Because MPs are very important substances to current economic activities, new materials for MPs will be needed such as cellulose. But before the alternative of the materials, contamination levels of these fine MPs in aquatic environment should be revealed. This study shows a new analytical technique to qualify and quantify these MPs in surface water. One of the new applied techniques is coagulation by Poly Aluminium chloride after density separation process. This new process can easily decrease matrices such as plant debris, algae, fine soils and other nonplastic particles on a membrane. Recovery tests were conducted using surface water contained known amount of three different size MPs and fiber type MPs. The results showed very good recovery rates of all types of MPs. After density separation, μFTIR microscopy with mapping image system and multiregression analysis. This system enables automated multi-point mapping, line mapping and IR Imaging analyses of a microscopic area with a manual sample stage and a single element detector. Though it is very difficult to quantify and qualify MPs of less than 100μm diameter by a stereoscopic microscope, this developed method can easily measure fine MPs on a membrane. The developed method can reveal characteristics of fine MPs in sewage water, sewage treated water, surface water with high concentration of suspended solids in order to evaluate their occurrence in aquatic environments and their ecological risk assessment.

**WP057 Biosolids inhibit the bioavailability and bioaccumulation of triclosan and triclocarban from microplastic to plants and earthworms**

*C. Sun, University of California, Riverside / Department of Environmental Science; J. Wang, University of California, Riverside; J. Gan, University of California, Riverside / Environmental Science*

Numerous varieties of microplastics enter agroecosystems from various routes and have potential for transporting chemical pollutants to organisms. Biosolid, rich in organic carbon, agronomic applications can increase the sorption of certain pollutants in soil, decreasing their bioavailability and bioaccumulation. This study tested the hypothesis that microplastic moves typical personal care products, triclosan and triclocarban, to the radish and earthworm, and the relative bioaccumulation of personal care products decreases with increasing biosolids amendment. Accumulation of triclosan and triclocarban was observed in roots of radish and earthworms grown in soils with 0.5%, 2% and 5% microplastics spiking with 200 mg $kg^{-1}$ pollutants. Addition of biosolids significantly decreased bioaccumulation of triclosan and triclocarban in roots of radish and earthworms. Using a thin-film passive sampler, polymethylmethacrylate film, we found that the availabilities of triclosan and triclocarban greatly decreased in biosolids-amended soils. The study provided the evidence that agronomic biosolid applications inhibit the bioavailability and bioaccumulation of personal care products from microplastic to plants and earthworms.

**WP058 Chemical analysis of ingested plastics and associated organic pollutants in wild-caught black sea bass, *Centropristis striata***

*J. Joseph, C. Stienbarger, University of North Carolina, Wilmington / Biology and Marine Biology; S. Athey, University of Toronto / Earth Sciences; B. Monteleone, University of North Carolina, Wilmington / Chemistry and Biochemistry; A. Andrady, NC State University / Department of Chemical and Biomolecular Engineering; W. Watanabe, P. Seaton, University of North Carolina, Wilmington; A.R. Taylor, University of North Carolina, Wilmington / Biology and Marine Biology; S.M. Brander, Oregon State University / Environmental and Molecular Toxicology*

The accumulation of microplastics in oceans, tiny granules of plastic < 5mm in diameter, is one of the major environmental concerns of our age. Due to their large specific surface area and hydrophobic properties, microplastics can absorb numerous organic pollutants. Intake of microplastics by marine organisms may therefore result in introducing toxicants to the organism itself and to the food chain, possibly leading to their bioaccumulation. Though a number of marine organisms have been found to ingest microplastics, few studies have been performed on commercial fishery species such as black sea bass (*Centropristis striata*). Here we have studied plastic ingestion by wild-caught black sea bass, an important fishery off the East coast of the United States. Our preliminary results showed that out of 102 fish sampled off the coast of North Carolina (from Beaufort, NC and Oak Island, NC), only 4 contained macroplastics. Work is in progress to digest samples in potassium hydroxide, followed by a series of filtration steps to isolate any microplastics or microfibers. We are using several spectroscopic and chromatographic techniques to characterize already-detected plastics and to identify the pollutants. Attenuated total reflection in conjunction with Fourier transform infrared spectroscopy (FTIR-ATR), and Raman spectroscopy were used to identify types of plastics. Using these techniques, we have already confirmed that one of the ingested plastics was poly(ethylene terephthalate) (PET). The identification of pollutants associated with the plastics was achieved by solvent extraction and subsequent gas chromatography-mass spectrometry (CG/MS) analysis. Tissue analysis will also be performed to understand the leaching of various chemicals and associated pollutants from the plastics. The extracts will be purified using Agilent bond elute Enhanced matrix removal (EMR-Lipid), a highly efficient method to remove lipids without impacting analyte recovery. Purified extracts will be analyzed with GC/MS-MRM (multiple reaction monitoring) method, a highly sensitive MS technique to selectively quantitate compounds from a complex mixture. We anticipate that our results from the analytical studies will contribute to the current knowledge on the plastic pollution in *C. striat*a and will inform both fishery management and potential concerns regarding human consumption of black sea bass that have ingested plastics.

**WP059 Enhancement of microplastics on PCB 126 accumulation in *Daphnia magna***

*M. Felix-Kim, Loyola University, Chicago / Institute of Environmental Sustainability; K. Renyer, Loyola University, Chicago / Department of Chemistry; P. Chiarelli, Loyola University, Chicago; T. Hoang, Loyola University, Chicago / Institute of Environment and Sustainability*

The abundance of plastics in bodies of water has exponentially increased, which has catalyzed researchers to explore the consequences that arise from this trend. Although there have been discoveries published, none of them have reported the potential effect of plastics on polychlorinated biphenyls (PCBs) accumulation in zooplankton-a primary food source of many higher trophic organisms in the aquatic ecosystem. The primary goal of this study is to determine if the adsorption of PCB-126 on microplastic enhanced the accumulation of this compound in *Daphnia magna* and biological performance (i.e., growth, reproduction) of the organisms. *Daphnia magna* was exposed to PCBs in water with the presence of microplastic or no plastic for 21 days. Results showed that *D. magna* consumed significant number of microplastics. PCB-126 was adsorbed on microplastics and carried into the organism's gut and resulted in higher accumulation of PCB-126 in the body of *D. magna*. While concentration of PCB-126 was not detected in control *D. magna*, exposed *D. magna* with the presence of microplastics had a body PCB-126 concentration of 30.28 mg/kg wet weight, which was significantly higher than the body PCB-126 concentration of exposed *D. magna* with no microplastics (17.39 mg/kg wet weight). Results of biological measurements showed that although there was no significant difference in the performance of exposed organisms versus the control organisms, *D. magna* appeared to perform poorer in water with the presence of microplastics and PCBs than in the control. Results of the present study poses a potential risk of plastic and PCBs transfer over to higher trophic organisms in the food chain.

**WP060 Field measurements to quantify microplastics in the San Francisco Bay and adjacent National Marine Sanctuaries**

*M.D. Sedlak, San Francisco Estuary Institute; C. Box, 5gyres; D. Lin, San Francisco Estuary Institute / Department of Civil and Environmental Engineering; R. Sutton, San Francisco Estuary Institute; X. Zhu, University of Toronto / Department of Ecology and Evolutionary Biology; C. Brookstone, N. Klasios, C.M. Rochman, University of Toronto*

Limited study of microplastics in the San Francisco Bay surface water suggests that Bay concentrations may be elevated in comparison to other North American locations. In addition, microplastics have been identified in fish from the Bay and the adjacent coast, indicating uptake of microplastic into the food web. In this study, microplastics were collected from the 16 sites in the San Francisco Bay and 11 sites in the Cordell Bank, Greater Farallones and Monterey Bay National Marine Sanctuaries using 20 micron pump filters and Manta trawls to characterize plastics less than 5 mm in size. The efficacy of pump vs. Manta trawl samples will be discussed. Microplastics were identified and quantified using optimized analytical methods. Discussion of sample results and understanding of the predominant polymers in microplastics and microfibers present in the Bay and sanctuaries will help to support identification of microplastic sources and to model the transport of these particles from the Bay to the surrounding ocean environment.

**WP061 Health hazard of drinking potable water stored in polythene sachet after exposure to direct sunlight**

*M.A. James, University of Nigeria, Nsukka / Department of Biochemistry; I.N. Onwurah, University of Nigeria / Biochemistry; A.I. Onwurah, University Of Nigeria, Nsukka / Environmental Management*

Packaging materials manufactured from polythene, its derivatives and other additives such as antioxidants, stabilizers, plasticizers, lubricants, antimicrobials, anti-static and anti-blocking agents, "slips," or heat resistance agents, are highly used in Nigeria for food and water. Under some environmental conditions such as heat, sunlight or UV radiation, these materials may undergo photolytic, photooxidative, and thermooxidative reactions which might produce toxic substances. If such compounds are produced and their concentrations surpassed a specified limit, quality and safety of the packaged content is compromised and this may have a serious implication for human health. In other to verify the above, eighteen (18) sachet water samples collected from three different factories (labelled A, B and C) in Nsukka, Enugu State were grouped in fives (5) and each of the three brands kept under the sun (UV) for one, two, three, four or five days. At the end of each exposure period, the sachet-water samples were collected and transferred into sterilized 200 ml Amber bottles. The samples which were not exposed were kept as control. The exposures were in triplicate. Degradation products for each exposure period were assayed using Gas Chromatography-Mass Spectroscopy with purge and trap (Agilent Technologies 7890A and 5975N mass selective detector). Some of the results obtained for sachet water from Factory A after one day exposure showed methylene chloride (16.82%), acetic acid (5.21%), octamethyl radical of cyclotetrasiloxane (5.63%) etc. Also at day 3 of exposure toluene (19.7%), 1-Dodecene, (Z) radical of 2-Dodecene and 1-Undecanol (14.3%), Xylene and 1, 3-dimethyl radical of Benzene (0.7%) etc were obtained. The same trends of results were obtained at the $4^{th}$ and $5^{th}$ day of exposure. Results for sachet water samples not exposed to sunlight (control sample) showed no trace of degraded components of polythene. Therefore, the presence of degraded components of polythene in sample from day 1 to 5 must have been due to photo-oxidation (sunlight exposure). The same trend followed for sachet water samples from Factory B and C. Some of these compounds have been confirmed by U.S. environmental protection agency (EPA) as a group c and group 2b possible human carcinogen and are widely acknowledged to have reproductive and developmental consequences as well as being possible human carcinogen.

**WP062 Identification of Microplastics Sized 3-500µm in Highly Urbanized Aquatic Environments**

*K.J. Wiggin, E.B. Holland, California State University, Long Beach / Biological Sciences*

Plastic production has drastically increased over the last 60 years, and consequently so has marine plastic pollution. Research demonstrates a vast prevalence of smaller plastic particles in aquatic environments, known as microplastics (MP;< 5mm). Common sampling protocols only sample plastics greater than 333µm, a common plankton net mesh size. To address this data gap, the presence of MP sized 3-500µm were assessed in Long Beach Harbor, the San Gabriel River, and the Los Angeles River (CA;USA), three areas with highly urbanized surroundings. Prior to sampling, the efficiency and accuracy of extraction and identification protocols utilized in previous MP detection studies were evaluated. For extraction efficiency, three commonly used digestion protocols were evaluated, including wet peroxide oxidation, enzymatic digestion (Cellulase), and hydrogen peroxide. For identification, the hydrophobic dye Nile Red was evaluated for its ability to dye plastic particles and organic materials in order to establish its efficacy as a secondary detection step. Digestion trials demonstrated that a 15% hydrogen peroxide exposure was highly efficient at digesting organic material, including natural fibers, and the entire protocol minimized contamination, degradation and loss of plastic particles. Additionally, Nile Red was found to exclusively dye plastic particles, and not organic materials. These methods were applied to 20L surface water grab samples from the field where prior to digestion, particles were size fractionated through sieves of various pore sizes. MP was then quantified and categorized under 40-200x magnification. Furthermore, 10% of MP samples were subject to Nile Red for secondary detection. This project will help establish a standard MP sampling, extraction, and identification protocol for sizes below 500µm and help to fully understand the prevalence of these smaller sized MP.

**WP063 Isolation and analysis of microplastic-associated additives using a previously described density separation unit**

*A.M. Lewis, Duke University / Civil and Environmental Engineering; L. Ferguson, Duke University / Nicholas School of the Environment Department of Civil and Environmental Engineering*

Microplastic particles are ubiquitous and heterogenous environmental pollutants. Vast differences in size, shape, and plastic type have been observed in sediment samples ranging from beaches to the deep sea. Each polymer type houses varying chemical additives and dyes to enhance the functionality and coloring of the material. Common polymer additives, such as nonylphenol and azo dyes, are of environmental concern due to their role as endocrine disrupters and suspected mutagens. Many studies have attempted to achieve efficient and thorough isolation of microplastics from sediment via floatation, density separation, and constructed separation units. However, few strategies have focused on isolation and analysis of the microplastic-associated chemical additives. In this study, a previously described density separation unit and protocol were assessed for the presence of polymer additives. The separation unit was constructed with clear polyvinylchloride (PVC) housing. A 1.5 g $cm^{-3}$ zinc chloride density solution was used so as to float heavier plastic types such as PVC. The recovery of spiked microplastics was determined for the protocol, as well as the associated chemical additives. The supernatant and remaining sediment were analyzed for the presence of polymer additives. Environmental sediment samples were collected from Ellerbe Creek, a local urban waterway. The samples were also separated by the tested protocol and analyzed for plastic-associated additives. Analysis included the use of a polymer additive and dye mass list in concert with the orbitrap lumos, as well as HPLC-ESI-MS/MS.

**WP064 Microplastics can impact the soil biophysical environment**

*A. de Souza Machado, Freie Universität Berlin / Institute of Biology; C. Lau, J. Till, Freie Universität Berlin; W. Kloas, Leibniz-Institute of Freshwater Ecology and Inland Fisheries; A. Lehmann, Freie Universität Berlin; R. Becker, BAM Federal Institute Materials Research and Testing; M.C. Rillig, Freie Universität Berlin*

Soils are essential components of terrestrial ecosystems that regulate a multitude of key environmental services such as biogeochemical cycling, biodiversity maintenance, and food security, among others. As a consequence, soils are directly impacted by multiple human activities to which they represent either the source or recipients of diverse common chemical and physical anthropogenic stressors. Microplastic contamination of soils is being increasingly documented, and its potential threats to terrestrial biodiversity and function have been recently conceptualized. Notwithstanding, data on effects of microplastics on fundamental properties potentially impacting soil biota are lacking. The present study explores the potential of microplastics to disturb vital relationships between soil and water, as well as its consequences for soil structure and microbial function. We exposed during 5 weeks a loamy sand soil to environmentally relevant nominal concentrations (up to 2 %) of four common microplastic types (polyacrylic fibers, polyester fibers, polyamide beads, and polyethylene high-density fragments). Then, we measured bulk density, water holding capacity, hydraulic conductivity, soil aggregation, and microbial activity. Diverse changes in the soil biophysical environment were observed. For instance, all microplastic types affected the bulk density soil. Both fibers significantly decreased microbial activity, while the polyester fibers increased the water holding capacity of soils. In addition, the soil structure, and the functional relationship between the microbial activity and water stable aggregates were also altered by microplastic exposure. The effects are underestimated if idiosyncrasies of particle type and concentrations are neglected, suggesting that purely qualitative environmental microplastic data might be of limited value for the assessment of effects on soil. If extended to other soils and plastic types, the processes unravelled here suggest that microplastics are relevant long-term anthropogenic stressors and drivers of global change in terrestrial ecosystems.

**WP065 Microplastics in the Mississippi River and Their Discharge to the Gulf of Mexico**

*K. Martin, Texas A&M, Corpus Christi / Department of Physical & Environmental Sciences; E. Hasenmueller, St. Louis University; J.R. White, Louisiana State University; L.G. Chambers, University of Central Florida; J.L. Conkle, Texas A&M University, Corpus Christi / Physical and Environmental Sciences*

Rivers are likely one of the greatest sources of plastic debris to the ocean, yet studies are just starting to quantify their contributions. The Mississippi River and its watershed encompass ~40% of U.S. land area and are home to >90 million people. Because of this large area and the plastic consumption potential of its population, the Mississippi River is likely one of the largest contributors of plastic debris to the global ocean. This research funded by the NOAA Marine Debris Program will quantify and characterize (size, shape, resin type) microplastics within the main stem and tributaries (Missouri, Illinois, and Ohio Rivers) of the Mississippi River near major cities such as St. Louis and New Orleans. Sample processing is ongoing, but preliminary estimates for the number of microplastics in the river and those potentially discharged to the Gulf of Mexico annually are in the quadrillions. Additional information that will be presented includes polymer type, spatial distribution and the influence of river volume on microplastic concentrations. The broader goal of this work is to create a baseline that can be used to guide fate and effects research as well as aid federal and local policymakers in creating and assessing mitigation strategies to improve water quality.

**WP066 Microplastics in the Mississippi River System**

*A. Scircle, University of Mississippi; J. Cizdziel, University of Mississippi / Chemistry*

Microplastics (MPs) concentrations on the inner shelf of the northern Gulf of Mexico (nGoM) are among the highest levels reported globally. Because their size range overlaps that of zooplankton, they are confused with prey and are accumulating in the food chain. The plastic particles are causing deleterious effects on aquatic organisms, particularly filter-feeders such as oysters. Moreover, plastics attract (sorb) certain contaminants, such as persistent organic pollutants and mercury, and thus their accumulation in biota may be an overlooked source of contaminants to ecosystems. This is a major concern to the state and region because seafood is a vital industry for Gulf Coast states, and because, on average, Gulf Coast residents consume more seafood than other U.S. residents. It is also a national problem because the majority of microplastics in the nGoM originate from the Mississippi River (MR), whose basin encompasses thirty one states. Yet, surprisingly little is known about the concentrations, types, sizes, and loadings of microplastics in the MR and its major tributaries. This lack of data is hindering our understanding of the magnitude and sources of the problem. This project aims to systematically quantify the concentrations and loads of MPs and characterize their shapes, size distribution, and chemical composition in the MR system—a source of drinking water to over 18 million people. We are collecting MPs using nets specifically designed for them and are using flow gauges to determine MP concentartions and loadings in the rivers. Wa are extracting and isolating the MPs using standard methods, including filtration, chemical treatment, and density separation. We are using fluorescence microscopy and µ-spectroscopic imaging to detect and identify the sizes, shapes, and composition of the MP contamination, including small MPs that are often overlooked. Here we will provide preliminary results for this ongoing work, determining the sizes, resin-type, and loads of MPs in the river system. This is important to assess possible relations between MPs levels and characteristics with sources and different watershed attributes.

**WP067 Microplastics loading estimation from urban areas to sewage treatment plants based from a monitoring campaign in Japan**

*Y. Kameda, Chiba Institute of Technology / Creative Engineering*

One of a main land-based sources of micropalstics released to aquatic environment is considered to be human activities such as our daily life, industrial activities, agricultural activities and so on. These microplastics are released to wastewater and runoff water from sources and finally flow into sewage treatment plants (STWs). To control the concentration in surface water, it is important to estimate the load from urban areas to STWs and reveal the removal rates at STWs. In this study, a microplastics monitoring campaign is performing in order to measure the concentration in raw wastewater samples and effluent water samples at approximately 20 STPs in Japan. The concentration variations in raw wastewater samples during a day are investigated. Microplastics in raw wastewater and effluent water samples are analyzed by a new method using density separation, coagulation process and μFTIR with imaging system and multi-regression analysis. Each polymer type microplastics less than 100μm are qualified and quantified into each shape types such as fragments, spheres, fibers and so on. Based on these data, microplastics loading per capita to STWs can be estimated statistically. Removal rates are also estimated at Japanese STPs. These data will be used to simulate their concentrations in rivers and bays near large cities by simulation models. This presentation will show some results in this monitoring campaign.

**WP068 Microplastics: Are they an ecological risk?**

*G. Burton, University of Michigan / School for Environment and Sustainability*

Not since the early days of assessing the impact of nanomaterials, has there been such a proliferation of research on a group of materials, as seen with microplastics (MPs). Widespread reports of trillions of MPs discharging into freshwaters, being a vector of contaminant bioaccumulation, and their toxicity quickly led to widespread banning of microbeads (one component of MPs). MPs are often reported in the same context as macro-plastics whose risks to large mammals, sea turtles, birds and fish are well known. The majority of research identifying adverse effects of MPs have only used microbeads, with exposures several orders of magnitude higher than the worst sites in nature. As with any substance, there can be no risk if there is no exposure. Nevertheless, there is a need for MP research addressing: 1) Risks in depositional sediments near urban wastewater discharges, particularly in regards to fibers which are much more common than beads; 2) Risk of very small MPs (sub-MPs) below 300 microns (e.g., anti-fouling paint chips and fibers); 3) MP and sub-MP ingestion in the presence of natural prey; and 4) Development of standard methods for sampling and quantifying MPs.

**WP069 Quantification of Benzotriazole Ultraviolet Stabilizers and Organophosphate Flame Retardants in Plastic Debris and Industrial Microplastics**

*B. Awonaike, Y. Lei, A. Parajulee, F. Wania, University of Toronto, Scarborough / Physical and Environmental Sciences*

Benzotriazole Ultraviolet Stabilizers (UV-BTs) and Organophosphate Flame Retardants (OPFRs) are used as additives in plastic products, added to prevent discolouration due to UV radiation and to comply with flammability standards, respectively. Mimico Creek is a highly urbanized watershed in Southern Ontario, Canada, which drains into Lake Ontario. The prevalence of UV-BTs in particles suspended in the water of Mimico creek has been previously shown, with the concentrations being the highest ever reported in the literature for this type of sample. However, the origin of these compounds in the creek is not clear. There is a high incidence of informal disposal of plastic waste within the Mimico Creek watershed, and furthermore, plastics manufacturing in Canada is concentrated in Southern Ontario and microplastics have been found to be prevalent in sediments collected from Lake Ontario tributaries. These present a possibility that UV-BTs are being leached out of plastics and into the creek. Some OPFRs have also been detected in surface water in Ontario, and these were also investigated since both groups of contaminants are found in similar products. This work aimed to quantify the UV-BT and OPFR content of plastic debris collected from Mimico Creek, and of pre-production plastic pellets and to infer whether these plastics serve as a source or a sink for these contaminants in the creek. Preliminary results indicate that the concentrations of UV-BTs and OPFRs in the plastics are too low (in the ng/g range) to make them viable sources. Additionally, the composition observed for UV-BTs are mirrored in the plastics and the creek water, further indicating that they are being sorbed onto the plastics from the water. We also observe that different types of polymers show varying affinities for sorption of UV-BTs. The trends for the OPFRs were similar, but not completely identical to Ontario surface water OPFR concentrations.

**WP070 Sorption behavior of NSAIDs on microplastics in freshwater environments**

*A. Elizalde Velazquez, T.A. Anderson, Texas Tech University / Environmental Toxicology; M.J. Green, Texas A&M University / Department of Chemical Engineering; J.E. Canas-Carrell, Texas Tech University / Environmental Toxicology*

High disposability, high durability and indiscriminate use have lead to the accumulation of plastics at uncontrolled rates in the environment. However, in the environment plastics are not the only source of water pollution; other contaminants can interact with the plastic debris. Studies have found that microplastics are able to adsorb and accumulate waterborne contaminants such as metals and hydrophobic organic compounds. Nontheless, there is a lack of data regarding the sorption of other important contaminants like pharmaceuticals and personal care products. Nonsteroidal anti-inflammatory drugs (NSAIDs) also known, as painkillers, are a group of pharmaceuticals widely and highly consumed in the market due to a low price and over the counter accessability. NSAIDs are frequently detected in the environment at μg/L concentrations. Furthermore, various studies have observed toxic effects of NSAIDs on various aquatic organisms at these same concentrations. Therefore, adsorption of NSAIDs on microplstics may result in long range transport and toxicity to aquatic organisms if ingested. Naproxen, ibuprofen and diclofenac have Log Kow values (3.18, 3.97 and 4.51) in the same range as persitant organic pollutants reported to have high partition coefficients with different microplastics. In the present study, we examine the sorption of three NSAIDs (ibuprofen, naproxen, diclofenac) with three types of microplastics (polystyrene (PS), ultra-high molecular weigth polyethylene (UHMWPE), and average molecular weight meduim density polyethylene (MDPE)) under freshwater conditions at different pHs. To investigate this process, isotherms will be determined using a Batch Equilibrium approach. Scanning Electron Microscopy (SEM) and Dynamic Light Scattering will be used to charcaterize the microplastics. It is expected that NSAIDs will be highly sorbed to UHMWPE, MDPE and PS microplastics, and sorption will be significantly correlated with Log Kow. Therefore, it is expected that distribution coefficients will be ordered in the following manner diclofenac (4.51) > ibuprofen (3.97) ≈ naproxen (3.18).

**WP071 The impact of carbon nanotubes (CNT) and ultraviolet light on the release of polymer additives from their microplastic matrices into the environment**

*I. Walker, Duke University / Civil and Environmental Engineering; M.D. Montaño, University of Vienna / Environmental Geosciences; L. Ferguson, Duke University / Nicholas School of the Environment Department of Civil and Environmental Engineering*

Engineered nanomaterials and nanoparticles are increasingly used in consumer products due to their properties and ability to be placed into composites. Nanoparticles such as carbon nanotubes are placed into polymer matrices to improve tensile strength, UV inhibition, flame resistance, electrical and thermal conductivity and reduce gas permeability. Many studies have investigated the impact of release of these nanoparticles into the environment and their ecotoxicological effects. However, few studies have investigated how the inclusion of carbon nanotubes in polymer matrices can impact the release of polymer additives. Polymer additives can be released through mechanisms of pH-mediated hydrolysis, oxidation, UV degradation, mechanical abrasions, and thermal degradation. The release of these additives into the environment are of concern due to additives like Bisphenol A and nonylphenol which are known to act as endocrine disruptors. In this study, a 5 day leaching experiments of cryomilled epoxy containing varying concentrations of carbon nanotubes (0, 0.01, 0.05, 0.1%) was completed. The three polymer additives that were studied are Bisphenol A (BPA), Bisphenol A diglycerol ether (BADGE), and Nonylphenol. The epoxy was placed in water under conditions of no light, and a temperature of 65 °C. This experiment was performed with one set of epoxy exposed to 5 days of 500 Watt UV exposure, while a control was run in parallel where epoxy was not exposed to UV. Daily measurements of polymer additive concentrations were taken to investigate how the concentration of carbon nanotubes and UV exposure increase the release of these polymer additives into an aqueous environment.

## Improving Chemical Assessments Using Toxicokinetic Data

**WP072 In vitro-in vivo and cross-life stage extrapolation of uptake and biotransformation of benzo[a]pyrene in the fathead minnow**

*C. Grimard, University of Saskatchewan; A. Mangold-Döring, M.T. Schmitz, RWTH Aachen University / Institute for Environmental Research; H. Alharbi, University of Saskatchewan / Toxicology Centre; P.D. Jones, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre; J. Giesy, University of Saskatchewan / Department of Veterinary and Biomedical Sciences and Toxicology Centre; M. Brinkmann, M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre*

An ever-increasing number of chemicals are used in our society that are eventually released into the environment. Current regulations to assess toxicological risks associated with these chemicals rely on extensive live-animal testing. Because of the costs and ethical concerns with regard to animal testing, the 3R principle (i.e., reduction, replacement, refinement) demands that animal experiments should be substituted with alternative test methods whenever possible. Computational models have been proposed as powerful in silico alternatives to animal experiments. Among these, toxicokinetic (TK) models have received particular attention because they can be used to predict the time course of a toxicant's concentration at the target site. Thus, they are not only useful to inform bioaccumulation assessments, but also help interpreting and extrapolating toxicological effect data. Current TK models are shown to be highly accurate for neutral organic chemicals if species specific chemical biotransformation is accounted for. Potential inter-species and life stage differences in biotransformation kinetics, however, are currently not well-understood. To bridge this gap, the goal of this study was: (a) to characterize in vitro transformation kinetics of the rapidly biotransformed model chemical benzo[*a*]pyrene (BaP) during different life stages of the fathead minnow (*Pimephales promelas*) using the S9 stability assay, (b) to develop and apply TK models for early life stage and adult fathead minnows to extrapolate biotransformation from in vitro to in vivo, and (c) to validate model predictions using data from in vivo flow-through exposures to graded concentrations of water-borne BaP. In addition to the study of substrate depletion, we will also account for life stage-dependent relative abundances of different BaP metabolites through ultra high-performance liquid chromatography and high resolution accurate mass mass spectrometry (UPLC-HRAM MS). Because different BaP metabolites have been shown to be associated with different toxicological effects, our models may also help to understand life stage-dependent differences in toxicological effects. In a next step, we will also characterize inter-species differences in biotransformation. Based on data acquired to date, we conclude that toxicokinetic models in combination with in vitro assays are a powerful alternative to in vivo experiments and can also account for life stage-specific differences in biotransformation.

**WP073 Quantitative in vitro to in vivo extrapolation of biotransformation rates for bioaccumulation assessment: Focus on organic sunscreen agents in trout**

*L.J. Saunders, Simon Fraser University; A.D. Hoffman, P.N. Fitzsimmons, J.W. Nichols, USEPA / ORD / NHEERL Mid-Continent Ecology Division; F. Gobas, Simon Fraser University / Resource & Environmental Management*

Recent studies demonstrate the utility of in vitro to in vivo extrapolation (IVIVE) approaches for estimating the impact of biotransformation on chemical bioaccumulation in fish. However, rigorous evaluation of the IVIVE approach requires studies that generate well-matched in vitro and in vivo data from the same species. Here we present results from both in vitro and in vivo experiments that measured biotransformation rates of two organic sunscreen agents (ultraviolet filters; UVFs), ethylhexyl trimethoxycinnamate (EHMC) and octocrylene (OCT) (log $K_{OW}$ of 5.8 and 6.9, respectively) in rainbow trout. For the in vivo studies, trout were exposed to three dietary concentrations of each UVF to investigate the relationship between dietary exposure concentration and observed accumulation and elimination. EHMC and OCT were significantly metabolized, resulting in mean in vivo biotransformation rate constants ($k_{MET}$) of 0.35 ± 0.05 and 0.09 ± 0.01 $d^{-1}$, respectively. In vivo $k_{MET}$ values did not differ between dietary exposure concentrations, indicating that UVF concentrations in the fish were not high enough to saturate biotransformation enzymes. In vitro biotransformation rates were measured in hepatic and intestinal S9 fractions under demonstrated first-order conditions ($C_i << K_M$). These values were then extrapolated to the whole animal to estimate $k_{MET}$. The $k_{MET}$ values determined for EHMC and OCT using in vitro data (hepatic plus intestinal) exhibited good agreement with measured values. Importantly, however, these comparisons suggest that biotransformation of EHMC occurs largely in the liver, while intestinal biotransformation plays a major role in elimination of OCT. Finally, the fraction unbound ($f_U$) was measured in S9 fractions and blood plasma for EHMC, OCT, and several other hydrophobic test chemicals representing a range in $\log_{KOW}$ (4-8). Measured $f_U$ values were then compared to predictions generated using available binding algorithms. We conclude that future use of quantitative IVIVE methods for bioaccumulation assessment requires greater consideration of extrahepatic metabolism and improved algorithms for estimating unbound chemical fractions in vitro and in blood.

**WP074 Assessing biotransformation and bioconcentration factors of fragrance materials using in vitro approaches**

*A. Lapczynski, D.T. Salvito, Research Institute for Fragrance Materials (RIFM) / Dept of Environmental Science; K.M. Johanning, KJ Scientific LLC / dba of Pura Vida Connections LLC*

Bioaccumulation potential measured as the bioconcentration factor (BCF) is one of the components for the PBT (persistent, bioaccumulative, toxic) criteria and risk assessment of chemicals by regulatory agencies in some regions of the world (e.g. REACH and ECHA). Biotransformation of chemicals is the largest source of uncertainty in bioaccumulation assessment. Currently, in vitro methodologies utilizing the rainbow trout metabolic assay not only are gaining interest, but are being used increasingly by several sectors as a crucial component in model-based estimates of BCFs and as part of a line of weight of evidence presented to regulators. The rainbow trout metabolic assay utilizing liver S9 fractions and cryopreserved hepatocytes to test chemical biotransformation has gone through a Ring Trial for an OECD validation process (OECD Project 3.13 coordinated by ILSI HESI) and the Test Guidelines and Guidance are being reviewed by the OECD assigned panel. In the present study four fragrance materials (Cyclabute, Melafleur, Trimofix and Verdox) with known measured BCF values obtained using OECD 305 method were tested for biotransformation utilizing both rainbow trout liver S9 fractions and cryopreserved hepatocytes. The results indicate that all four fragrance materials were metabolized in both biological systems at different rates, but in all cases the BCFs determined were comparable to the measured in vivo BCF values. The in vitro metabolic assay is a powerful tool that can be used to determine BCF of test chemicals and provide data to build the database information on fragrance materials for fish metabolism and modeling.

**WP075 Multi-compartmental toxicokinetic modeling of fipronil in tilapia: Accumulation, biotransformation and elimination**

*H. Li, Jinan University; J. You, Jinan University / School of Environment; W. Wang, Hong Kong University Sci. Technol. / Department of Ocean Science*

Bioaccumulation and biotransformation are the critical processes modifying the toxicity of easily metabolizable chemicals. In the present study, tissue-specific accumulation, biotransformation and elimination of a pesticide fipronil in tilapia (*Oreochromis niloticus*) were quantified by combining in vivo measurements and a newly developed multi-compartmental pharmacokinetic model. Waterborne fipronil was taken up via gills and metabolized rapidly and solely to fipronil sulfone, which had three-fold higher whole body concentration and 30-fold longer half-life in tilapia than the parent compound. The highest concentrations of fipronil and fipronil sulfone were detected in the liver, followed by intestine, gill, bile, carcass and blood. Significant decrease of fipronil residues in the liver and intestine during exposure period strongly suggested the metabolism in these two organs. Intestinal transformation of fipronil was as important as hepatic transformation in the waterborne exposure. Significant transport of fipronil and fipronil sulfone in the liver-bile-intestine system implied that hepatobiliary excretion and enterohepatic re-absorption played important roles in fipronil metabolism and system circulation of the parent compound and the metabolite. The multi-compartmental model quantitatively demonstrated the highly dynamic inter-compartmental transport and rapid branchial clearance of fipronil in fish. Modeling results also suggested that uptake and biotransformation were the stronger driving forces for the inter-compartmental transport of xenobiotics in fish than the inherent partitioning capacity.

**WP076 Parameter Optimization and Statistical Analysis of PBTK Models for Fluoranthene Exposure in Rainbow Trout**

*I. Edhlund, Clemson University ENTOX; C.M. Lee, Clemson University / Environmental Engineering and Earth Sciences Department*

Physiologically based toxicokinetic (PBTK) modeling in fish offers great promise in environmental risk assessment, potentially speeding up dose-response studies while minimizing animal testing. Some limitations exist in the PBTK field, such as difficulty of model development and a lack of application specific software tools to help modelers. These limitations have slowed the progress of PBTK modeling for risk assessment. In a closely related field, physiologically based pharmacokinetic (PBPK) modeling has been used for drug development. Several recent publications have discussed the requirements for PBPK modeling in regulatory submission which are analogous to the needs of PBPK modeling. The requirements include standards for distribution and documentation of models, statistical methods for optimization and validation of models, databases for physiological parameters, and better software tools. Our previous research addressed some of these requirements by presenting Petri Nets as an open source, unified method for simulating, documenting, and distributing PBTK models in fish. The current research expands on this by offering an open source tool for optimizing PBTK parameters, performing sensitivity and variability analyses, and conducting statistical evaluations of the PBTK models. The software is demonstrated by comparing different PBTK models of fluoranthene exposure in rainbow trout. The models differ in the metabolizing compartments, where specific assumptions regarding phase I vs phase II metabolizing enzymes are tested. Various algorithms are compared to optimize parameters for each model. Statistical analysis results are used to determine the best fit among the models.

**WP077 General Unified Threshold Model of Survival (GUTS) Model of the Effects of Perfluorooctanic Acid on Loggerhead (*Caretta caretta*) Sea Turtle Cells**

*J.D. Pierro, Texas Tech University / TIEHH / Environmental Toxicology; A.L. Peace, Texas Tech University / Department of Mathematics and Statistics; S.J. Webb, Texas Tech University / TIEHH / Department of Environmental Toxicology; B.M. Higgins, NOAA National Marine Fisheries Service; C.A. Godard-Codding, Texas Tech University / TIEHH / Department of Environmental Toxicology*

Loggerhead (*Caretta caretta*) sea turtles are a threatened species, and yet little toxicological research has been conducted on them. This study entails toxicity testing of Perfluorooctanic Acid (PFOA) on loggerhead sea turtle cells, followed by the production of a mathematical model that predicts survival based upon the empirical data. PFOA is a common component in non-stick coating on pans, a surface repellent in carpet, paper, and cardboard, and an ingredient in fire-fighting foam. This toxicant is known for its cytotoxicity, mutagenicity, immunotoxicity, adverse developmental effects, and negative impacts on renal and hepatic systems in multiple animal models, including reptiles. Cytotoxicity of PFOA on loggerhead skin was examined using the MTT viability assay to assess primary skin cell cultures exposed to environmentally relevant concentrations for 24, 48, 72, and 96 hours. This toxicological data was then used in the General Unified Threshold Model of Survival (GUTS) to provide a framework for the prediction of loggerhead sea turtle cell survivability overtime. GUTS delivered a guideline for parameterizing sound toxicokinetic toxicodynamic (TKTD) models that effectively looked at the sensitivity of loggerhead cells to PFOA. There are two survivability models that resulted from the use of GUTS – individual tolerance (IT) and stochastic death (SD). IT forecasted survivability based on the individual sensitivity of each cell; all cells have individual tolerance levels for the contaminant. The SD approach predicted survivability based on the idea that all cells share a common adverse effect threshold, and similarly have decreased likelihood of survivability at the same rate. The SD and IT approaches provided valuable and novel insight into the survivability risks PFOA poses to loggerhead sea turtles. Both SD and IT models were analyzed for effectiveness using confidence intervals and profile likelihoods. Each model served as a tool for conducting standard ecological risk assessments through the establishment of a fifty percent lethal concentration ($LC_{50}$) prediction at various exposure time points. These models provided the first GUTS models for this marine reptile and the first application of GUTS to cell populations rather than individual animals, pioneering the advent of TKTD models for endangered species that cannot undergo normal toxicity testing.

**WP078 Updated Models for Predicting Biotransformation Impacts on Chemical Bioconcentration in Rainbow Trout**

*J.A. Arnot, ARC Arnot Research & Consulting / Department of Physical & Environmental Science / Department of Pharmacology and Toxicology; M. Embry, HESI; J.M. Armitage, AES Armitage Environmental Sciences, Inc / Physical and Environmental Sciences; J.W. Nichols, USEPA / ORD / NHEERL / Mid-Continent Ecology Division*

Biotransformation may substantially reduce chemical accumulation in fish, and is a recognized source of uncertainty in many bioaccumulation assessments. Here we describe and compare two one-compartment toxicokinetic models that can be used to predict the effect of hepatic biotransformation on bioconcentration factors (BCFs) in rainbow trout (*Oncorhynchus mykiss*). Both models employ established methods to extrapolate in vitro intrinsic clearance rates measured using liver S9 fractions or isolated hepatocytes to the whole animal; however, one model relies of QSARs to predict rates of chemical uptake and elimination while the other describes these processes in physiological terms. Compared to the QSAR-based model, the physiological model more explicitly addresses how differences in fish size and water temperature affect rate constants for chemical uptake and elimination (e.g., branchial uptake) in the fish. In addition, the physiological model provides a more direct link to previously published estimates of whole-body biotransformation rate constants ($k_B$), derived from in vivo BCF and dietary bioaccumulation tests in various fish species. BCFs predicted by the physiological model in the absence of biotransformation are somewhat higher than those generated by the QSAR-based model, due to differences in predicted chemical partitioning. However, the physiological model predicts lower BCFs for compounds that undergo biotransformation at all but very low levels of biotransformation activity. This difference in predicted BCFs varies with log $K_{OW}$ and the biotransformation rate, and in some instances exceeds 1.5-fold ($BCF_{QSAR}/BCF_{Phys}$). The utility of the physiological model was demonstrated by calculating $k_B$s for a suite of polycyclic aromatic hydrocarbons using measured in vitro biotransformation rate data. The resulting $k_B$s exhibit remarkably good agreement with in vivo and in silico (QSAR) estimates. Finally, uncertainty in model selection for BCF calculation was put into context by highlighting variability and uncertainty in measured in vivo BCFs.

**WP079 Developing and testing models to integrate toxicokinetic data for assessing bioaccumulation in mammals**

*J.A. Arnot, ARC Arnot Research & Consulting / Department of Physical & Environmental Science / Department of Pharmacology and Toxicology; J.M. Armitage, AES Armitage Environmental Sciences, Inc. / Physical and Environmental Sciences; E. Papa, University of Insubria / Department of Theoretical and Applied Sciences (DiSTA); M. Embry, HESI; A. Sangion, University of Insubria / Department of Theoretical and Applied Sciences (DiSTA); L. Bertato, A. Pohlenz Perez, University of Insubria; K.L. Foster, KFER Karen Foster Environmental Research / Trent University, Applications of Modelling & Quantitative Methods (AMOD); A. Looky, ARC Arnot Research and Consulting Inc.; J. Wyatt, E. Ramos, University of Toronto; L. Toose, Liisa Toose Environmental Research*

Historically, the globally accepted model for bioaccumulation (B) assessment has been fish, and B screening and assessment has been driven by the octanol-water partition coefficient ($K_{OW}$) and data and assessment endpoints for aquatic species; however, nearly two decades of evidence has highlighted the need to examine B in air-breathing organisms as well. Emerging regulatory guidance, e.g., REACH Chapter R11: PBT / vPvB Assessment, includes B screening threshold criteria for air-breathing organisms linked to $K_{OW}$ and the octanol-air partition coefficient ($K_{OA}$). It is also acknowledged that considerations of the dietary absorption efficiency of the chemical and biotransformation rates are also necessary for B assessment. Tools, models and data streams are emerging to aid in B assessment for mammals such as in silico models to predict chemical partitioning and biotransformation half-lives and in vitro and in vivo data that can be used to parameterize toxicokinetic (TK) models such as in vitro biotransformation rates estimated from hepatocytes. While certain tools for simulating B in mammals and other air-breathing organisms exist, it is desirable to further develop and refine tools and data streams more explicitly and to evaluate (test) these frameworks. This project expands the development and evaluation data and models for B and exposure and risk assessment for mammals. A particular focus of this project is to address data gaps and uncertainty in biotransformation half-lives. The initial objective of the project is to assimilate critically evaluated data from various sources of in vitro and in vivo TK data (rodents and humans), as well as field B data in mammals (e.g., biomagnification factors). This poster will describe initial efforts to assimilate these data, as well as highlight future project goals and tasks (i.e., exploring new Quantitative Structure-Activity Relationships (QSARs) to predict biotransformation rates and other key TK data).

**WP080 Literature-Derived Bioaccumulation Models for Polychlorinated Biphenyls in Plants and Small Mammals**

*S. Yu, P.C. Fuchsman, K. Fetters, L. Brown, Ramboll*

We reviewed literature on the bioaccumulation of polychlorinated biphenyls (PCBs) in plants and small mammals, to support the wildlife exposure characterization for an ecological risk assessment. Suitable field studies for this analysis reported soil and whole-body (or similar) tissue PCB data from the same site, and all studies included were reviewed for appropriate study design, documentation, and data quality. For plants, extensive data are available from phytoremediation research and other studies; we selected five representative field studies that provided data for multiple non-agricultural plant species. For small mammals, a comprehensive review of peer-reviewed and gray literature was necessary to obtain an adequate data set, and seven field studies were identified. Bioaccumulation regressions were selected over point-estimate bioaccumulation factors for application in the food web model, if a statistically significant linear relationship ($p< 0.05$) existed between soil and tissue PCB concentrations, because such regressions provide a more robust estimate of bioaccumulation across a range of soil concentrations. Due to limited availability of lipid and organic carbon data, analyses were performed without normalizing for these factors. Additionally, lipid and organic carbon normalized data were analyzed for a subset of the small mammal data, representing sites contaminated with less-chlorinated PCB mixtures. For plants, bioaccumulation of PCBs in wetland and upland species did not differ. Therefore, a single statistically significant regression equation based on all available data for wetland and terrestrial plants was used in the food web model. For small mammals, bioaccumulation of PCBs was found to be significantly higher in shrews than in other small mammals (i.e., mice and meadow voles), consistent with the higher trophic position and soil ingestion rates of shrews compared to other small mammals. Therefore, bioaccumulation was estimated separately for shrews and other small mammals, and the regressions were both statistically significant and used in the food web model. The resulting bioaccumulation models were sufficiently robust to allow site-specific sampling to focus on other food web components with higher bioaccumulation potential, without the need to sample and analyze site-specific PCB concentrations in plants and small mammals.

**WP081 Multi-Species Approach in Physiologically Based Toxicokinetic (PBTK) Modelling in Support of Ecological Risk Assessment**

*A. Mangold-Döring, RWTH Aachen University / Institute for Environmental Research (Biology V); C. Grimard, University of Saskatchewan; D. Green, University of Saskatchewan / Toxicology Centre; N.S. Hogan, University of Saskatchewan / Department of Animal and Poultry Science and Toxicology Centre; L.P. Weber, University of Saskatchewan / Veterinary Biomedical Sciences; H. Hollert, RWTH Aachen University / Institute for Environmental Research; M. Hecker, M. Brinkmann, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre*

The production and release of chemicals by our society has been described as one of the greatest threats to the sustainability of human activities on this planet. Legislations of varying rigor have been implemented globally and seek to minimize impacts of chemicals on the environment through ecological risk assessments (ERA). The foundation of ERA are standardized toxicity data which are generated in laboratory experiments with model species. However, these species are not necessarily representative of native species of concern in an ecosystem. Furthermore, a wealth of data from non-model species is available in the scientific literature but cannot be utilized in ERA because the data were not derived in compliance with test guidelines. Therefore, approaches are needed that enable inclusion of these data, such as models, that enable transposing these datasets into a format that is useful in ERA. One class of models that facilitate extrapolation between levels of biological organization, exposure conditions, and among species are physiologically based toxicokinetic (PBTK) models. In our previous research we successfully re-parameterized a single-species PBTK model for multiple species and integrated this model into a multispecies modeling framework. In contrast to this "top-down" approach, here we present a "bottom-up" multispecies PBTK modeling framework which will be based on available data from the 222 freshwater fishes found in Canada. This approach – unlike all previous models – does not require full sets of model parameters to define individual species fully but will rather make use of a database of all available data to describe the statistical distributions of model parameters. These distributions are then used to feed into random number generators in stochastic Monte Carlo simulations to make probabilistic cross-species toxicokinetic predictions. In addition to enabling cross-species extrapolations in ERA, our novel stochastic multispecies PBTK model provides a framework that can help address various environmentally relevant questions by providing predictions for specific taxonomic, ecological, or geographic groups of fishes. As such, our new model will potentially enable more environmentally relevant predictions using already existing data, and could ultimately lead toward more sustainable use of existing data.

**WP082 The Bioaccumulation Assessment Tool (BAT): A quantitative weight of evidence approach for bioaccumulation assessment**

*L. Toose, Liisa Toose Environmental Research; J.M. Armitage, AES Armitage Environmental Sciences, Inc. / Physical and Environmental Sciences; L. Hughes, ARC Arnot Research & Consulting; K.L. Foster, KFER Karen Foster Environmental Research / Trent University, Applications of Modelling & Quantitative Methods (AMOD); M.R. Embry, Health and Environmental Sciences Institute (HESI); J.A. Arnot, ARC Arnot Research & Consulting / Department of Physical & Environmental Science / Department of Pharmacology and Toxicology*

Chemicals are assessed for bioaccumulation (B) potential in regulatory programs using various methods, metrics and criteria. The Bioaccumulation Assessment Tool (BAT) was developed to standardize the collection, evaluation and the integration of various lines of evidence (LOE) with available toxicokinetic (TK) information and related B classification criteria to aid decision-making. The BAT provides a transparent and consistent framework for the evaluation of neutral and ionizable organic chemicals in aquatic and terrestrial organisms. It uses a quantitative weight of evidence (QWOE) approach which includes assessments for the relevance, reliability (confidence) and outcome of each B-metric source. Each substantive LOE (e.g., bioconcentration factor (BCF), biomagnification factor (BMF), trophic magnification factor (TMF), biotransformation rate, etc.) is subject to a standardized data quality evaluation resulting in a data reliability score by which the outcome of the LOE can be weighted. The Data Evaluation Templates (DETs) have been derived from standard test protocols (OECD) and expert judgment when standard protocols are not yet developed. Physical-chemical properties can be used or the user may enter biologically-relevant partition coefficients in place of default assumptions that assume octanol as surrogate for biological components (i.e., lipid). Estimates for biotransformation rates can be included from in vitro assays (i.e., S9, hepatocyte, microsomal), from in silico (QSAR) and in vivo study predictions. Empirical, in vivo study data including lab BCFs and BMFs and field data as well as in silico data (e.g., BCF-QSARs) can be assessed for reliability and included in the QWOE. We provide an overview of the BAT and demonstrate its application with two case studies. The first example is a typical "data poor" scenario in which only chemical structure information is available. From chemical structure relevant physical-chemical property and biotransformation rate data are obtained from QSARs and entered into the BAT. The second case study is for a relatively "data rich" chemical for which various LOE exist (e.g., 3 lab BCFs, various BCF-QSARs, biotransformation rate QSARs, in vitro biotransformation rates).

## Emerging Flame Retardants: State-of-the-Art Knowledge and Addressing Research Gaps

**WP083 Emerging flame retardants: A review of current policy approaches and critical research needs to inform evidence-based policy**

*V. Singla, University of California, San Francisco / Program on Reproductive Health and the Environment / Obstetrics, Gynecology and Reproductive Sciences; T. Woodruff, University of California, San Francisco / Program on Reproductive Health and the Environment*

The phase out of PBDEs and HBCDD resulted in a large number of halogenated and non-halogenated chemicals being used as replacement flame retardants in furniture, children's products, electronics and building materials. Studies find almost 50 unique replacement flame retardants in U.S. indoor dust samples alone. Chemical policies have generally managed flame retardants through a paradigm of allowing use while conducting an in-depth, quantitative risk assessment of specific chemicals to inform risk management. Risk assessments include studies of human exposures and effects, and if the chemical is found to be harmful, health damages may already have occurred prior to regulatory decisions. Further, risk management has usually focused on ceasing manufacture and import while not addressing existing products containing flame retardants. This is especially problematic for persistent and bioaccumulative chemicals where products in situ, disposal and recycling will result in the chemicals' presence and exposures for decades after manufacture is banned. However, there is increasing recognition that this paradigm is insufficient to address current chemicals and their exposures before harm or keep pace with the proliferation of new chemicals. This presentation will review new policy approaches being taken by businesses, cities, states, countries and international bodies to attempt to address existing and emerging flame retardants such as: disclosure of information on flame retardants in products; considering classes of flame retardants instead of single chemicals; regulating recycling/ disposal of flame-retarded products; and alternatives assessments for flame retardants. For example, the 2016 Lautenberg amendments to the U.S. Toxic Substances Control Act mandate that exposures to persistent, bioaccumulative and toxic (PBT) chemicals be eliminated to the extent practicable—meaning that for the first time, the Environmental Protection Agency is required to assess existing products containing PBT flame retardants. The Consumer Product Safety Commission is currently evaluating scientific approaches for considering all halogenated flame retardants as a class for regulation. The types of scientific information needed for new policy efforts will be compared and contrasted with what is needed for risk assessment, with recommendations for making research on emerging flame retardants relevant and translatable to inform policy.

**WP084 Greener Fire Safety Solutions for Interior Automotive & Building Insulation**

*T. Reilly, Clariant Plastics & Coatings USA / BU Additives*

For several decades, there have been numerous peer reviewed scientific studies documenting human health and environment concerns of certain organohalogen flame retardants. TDCPP and TCPP are organohalogen flame retardants used in large volume within North America (re. automotive, Building & Construction). The U.S. Consumer Product Safety Commission has recently expressed concerns about the use of organohalogen FRs in certain consumer goods. This presentation will review two large volume FR applications where organohalogen flame retardants are used (interior automotive, building insulation). The audience will be informed that Greener FR solutions are already commercially available which meet existing fire safety requirements.

**WP085 First Steps Towards Characterization of Polyhalogenated Alkane (PXA) Flame Retardants**

*L. Chibwe, A.O. De Silva, Environment and Climate Change Canada / Aquatic Contaminants Research Division; A. Myers, Ontario Ministry of the Environment and Climate Change; E.J. Reiner, University of Toronto / Laboratory Services Branch; K.J. Jobst, Ontario Ministry of Environment and Climate Change; D.C. Muir, Environment and Climate Change Canada / Aquatic Contaminants Research Division*

Brominated/chlorinated alkenes have been used for over 20 years as flame retardants, but are not currently registered in Europe under REACH. As polyhalogenated alkanes (PXAs), they are expected to resemble chlorinated paraffins in toxicity and environmental behavior. The objective of this work is to characterize a commercial brominated/ chlorinated alkene product as an initial step towards understanding the environmental occurrence and persistence of PXAs. A sample of Doverguard 8207, purportedly containing $C_{12-30}$ brominated/chlorinated alkenes (CAS# 68527-01-5) was run by four different high resolution techniques: GCxGC-EI(+)-HRMS, GC-APCI(-)-HRMS, LC-APCI(-)-Orbitrap MS, and FTICR-MS in negative mode. Medium (MCCP) and long chain (LCCP) chlorinated paraffins were also analysed for comparison. Analysis by GCxGC-EI(+)-HRMS results indicated that 68527-01-5 consisted mainly of chains lengths of 18 or more carbons, substituted with several chlorine and bromine atoms. GC-APCI(-)-HRMS yielded five prominent PXA ions with proposed elemental compositions of $C_{18}H_{31}Br_2Cl_4$-, $C_{18}H_{31}BrCl_5$-, $C_{18}H_{30}BrCl_6$-, $C_{18}H_{30}Br_2Cl_5$-, and $C_{18}H_{29}Br_2Cl_6$-. Although molecular ions were not observed for several of these PXAs, their identification was confirmed through FTICR-MS analysis. The addition of DCM between the source and column resulted in exclusive formation of [M+Cl]- adducts for the CP standards, in agreement with previous studies. The most prominent PXA ions identified by LC-APCI(-)-Orbitrap MS, in order of decreasing abundances, were $C_{18}H_{32}Br_2Cl_5$-, $C_{18}H_{31}$Br2$Cl_6$-, $C_{18}H_{30}Br_2Cl_7$-, $C_{18}H_{31}Br_3Cl_5$-, and $C_{18}H_{33}Br_2Cl_4$-. LC-Cl-enhanced APCI (-)-Orbitrap appears to form [M+Cl]- ions, and corroborates the formation of either [M-H]- or [M-X]- ions in GC-APCI(-)-HRMS, based on the prominent PXA ions observed in both methods. The data obtained so far confirm industry information that this substance has a Cl:Br ratio of ~2.6:1 but do not entirely support the data description of the product as $C_{12}$-$C_{30}$ bromo/chloro-alkene. Assuming that bromo-chloro-$C_{18}$ alkanes are the major constituents, 68527-01-5 contains very hydrophobic molecules. Log Kows for the main $C_{18}$ alkanes ions in 68527-01-5 were estimated by correlations with LC retention time of a suite of 21 hydrophobic organics. Estimated log Kow for major Br/Cl-PXA components with C18 chains ranged from 6.4 to 6.9. This was lower than estimated using KOWWIN for representative Br/Cl-C18 PXAs which ranged from 10-11.

**WP086 Measurement of physicochemical properties of EH-TBB, BEH-TEBP, and TPHP, and differences in their properties between pure substance and mixture**

*H. Kuramochi, National Institute for Environmental Studies, Japan / Center for Material Cycles and Waste Management Research; K. Yui, National Institute for Environmental Studies, Japan; S. Endo, Osaka City University / Urban Research Plaza & Graduate School of Engineering; S. Sakai, Kyoto University / Environment Preservation Research Center; Y. Chen, University of Toronto at Scarborough; F. Wania, University of Toronto at Scarborough / Physical and Environmental Sciences*

Recently, environmental occurrences of non-PBDE (polybrominated diphenyl ethers ) brominated flame retardants (BFRs) such as “novel BFRs,” “emerging BFRs,” etc., have been reported by various research groups. In order to understand the environmental fate and mechanism of contamination of these chemicals, knowledge of their physicochemical properties, such as vapor pressure ($p_i$), water solubility ($S_w$), and 1-octanol–water partition coefficient ($K_{ow}$) is necessary. Therefore, we have measured these properties for several non-PBDE BFRs. In this study, we newly measured the properties of 2-ethylhexyl-2,3,4,5-tetrabromobenzoate (EH-TBB) and bis(2-ethylhexyl)-3,4,5,6-tetrabromophthalate (BEH-TEBP). The following is a brief summary of the methods used to measure $S_w$, $K_{ow}$, and $p_i$ values. The $S_w$ and $K_{ow}$ at 298 K were measured with a direct coupled column linked chromatographic technique and the slow stirrer method, respectively. We used the generator column method for the $p_i$ measurement at elevating temperatures. The $p_i$ value at 298 K ($p_i^o$) was determined by fitting the vapor pressure data with the Clausius−Clapeyron equation. Compared with some PBDEs and non-PBDE BFRs measured in our previous works, $p_i^o$ values of EH-TBB ($6.20\cdot10^{-6}$ Pa) and BEH-TEBP ($1.08\cdot10^{-8}$ Pa) were similar to those of BDE-99 (PBDEs with 5 bromines, $3.67\cdot10^{-6}$ Pa ) and BDE-153 with 6 bromines ($1.28\cdot10^{-8}$ Pa), respectively. In terms of log $K_{ow}$ and $S_w$, however, EH-TBB (7.02 and $6.15\cdot10^{-4}$ mg/L) and BEH-TEBP (7.65 and $1.19\cdot10^{-6}$ mg/L) were lower than BDE-99 (7.35 and $3.47\cdot10^{-3}$ mg/L) and BDE-153 (8.05 and $5.04\cdot10^{-5}$ mg/L) , respectively. EH-TBB and BEH-TEBP are main BFR components in a commercial product Firemaster 550. This product also contains another organophosphorous flame retardants such as triphenylphosphate (TPHP). Actually, a liquid mixture of those compounds is used. In this study, we investigated if there are any differences between pure state and mixture states in terms of physicochemical properties. We expected the differences could not be predicted by the ideal solution assumption, since the activity coefficient values of the three flame retardants in their mixtures estimated by COSMOtherm were higher than unity. Therefore, we measured the properties for pure TPHP, and then tried to measure $p_i$ and $S_w$ of the three components in a mixture state. At our presentation, we show the difference among the pure and mixed-state properties.

**WP087 Investigation of flame retardants incorporated into plastic enclosures of liquid crystal display monitors for personal computers on Japanese market**

*H. Matsukami, N. Kajiwara, National Institute for Environmental Studies / Center for Material Cycles and Waste Management Research*

The restriction against polybrominated diphenyl ether (PBDE) flame retardants (FRs) according to the RoHS Directive in the EU was introduced the increasing application of alternative halogenated FRs (AHFRs) and organophosphorus FRs (PFRs) in polymeric materials of electronic products all over the world. However, emerging concerns are raised about environmental contamination and human health risks posed by AHFRs and PFRs. Information on the types and concentrations of FRs in polymeric materials of electronic products currently on market is crucial for the assessment and prediction of environmental contamination and human health risks posed by FRs derived from the use and processing of electronic products. Nevertheless, no definitive information exists for the presence of FRs in plastic enclosures of liquid crystal display monitors for personal computers. We investigated the presence of PBDEs, AHFRs, and PFRs in the plastic enclosure samples collected from 45 liquid crystal display monitors for personal computers by GC-EI-QMS and LC-ESI-MSMS measurements. These monitors were manufactured by 15 display technology companies in China, Japan, South Korea, and the United States through 2001 to 2013 and, consequently, they were put on Japanese market in 2015. Of the 45 monitors, all the monitors measured in this study have fulfilled the RoHS threshold for PBDE concentrations (0.1%). Two monitors manufactured before the RoHS Directive were determined to contain tetrabromobisphenol-A with the same concentrations of 14%, whereas two monitors manufactured after the RoHS Directive were determined to contain two AHFR mixture including decabromodiphenyl ethane and 2,4,6-tris(2,4,6-tribromophenoxy)-1,3,5-triazine with the total concentration range from 13 to 14%. The 21 monitors manufactured over the course of the period between 2001 and 2011 were determined to contain three oligomeric PFRs, such as bisphenol A bis(diphenyl phosphate), resorcinol bis(diphenyl phosphate), and resorcinol bis(dixylyl phosphate), with the concentration range from 4.4 to 9.2%. The remaining 20 samples were expected to contain unknown halogen-free FRs on the basis of the results from element screening using a handheld X-ray fluorescence analyzer.

**WP088 Nationwide Distribution of 19 Organophosphate Flame Retardant (OPFRs) in Indoor Dust, Outdoor Dust and Soil in China**

*Y. Wang, Wadsworth Center / New York State Department of Health / College of Environmental Science and Engineering; X. Han, Y. Yao, Nankai University / College of Environmental Science and Engineering; W. Li, H. Zhu, Wadsworth Center / New York State Department of Health; H. Sun, Nankai University / College of Environmental Science and Engineering; K. Kannan, Wadsworth Center / New York State Department of Health / Division of Environmental Health Sciences*

Organophosphate flame retardants (OPFRs) have received attention in recent years due to their widespread usage (e.g., in plastics, electronic products), increasing production (>680,000 tons/year), occurrence in environmental matrices and adverse impact on human health. A few studies in China showed elevated contamination by OPFRs in certain localized regions. However, the studies on nationwide distribution of OPFRs are limited. In the present study, 19 OPFRs were measured in 44 indoor dust (ID), 97 outdoor dust (OD) and 100 soil (S) samples collected from different regions of China. ∑19OPFRs level in indoor dust (2380 ng/g; median) was much higher than outdoor dust (446 ng/g) and soil (36.4 ng/g) samples. OPFR concentrations in outdoor matrices showed a positive correlation with the population density of various regions in China. Northeastern China with the traditional industrial base, and the Eastern and Southcentral China with high population density and economic development had significantly higher levels of OPFRs than the other areas. Samples from Guangdong province, which is the world center for electronic waste recycling, contained extremely high OPFR level (ID:5700 ng/g), indicating that e-waste is still an important source of OPFRs. Tris(2-chloroisopropyl) phosphate (TCIPP) had the highest detected frequency (DF; >95%) and concentration (ID:690, OD:85.8, S:14.5 ng/g). Cresyl diphenyl phosphate (CDPP) and Isodecyl Diphenyl Phosphate (IDDP) were also detected (DF>80%) at considerable levels (ID:3.85-10.6, OD:2.04-5.48, S:0.39-0.14 ng/g) revealing their increasing usage in China. Aryl-OPFRs showed significant correlations ($r$=0.326-0.855, $p$< 0.05) with each other in all three matrices. There was a significant but weak correlation between OPFRs concentration in paired indoor-outdoor dust ($r$=0.475, $p$< 0.01) and outdoor dust-soil ($r$=0.437, $p$< 0.01) samples. Adults intake (EDI) through dust ingestion was estimated at 0.55 ng/kg bw/d ∑19OPFR while children intake at 6.84 ng/kg bw/d. EDI values from outdoor environment were less than 5% of that from indoor and the dust ingestion was the major pathway (>98%) of OPFRs exposure.

**WP089 Occurrence of OPFRs/plasticizers in indoor air and the associated human exposures**

*Y. Wang, Wadsworth Center / New York State Department of Health / College of Environmental Science and Engineering; U. Kim, Korea Institute of Toxicology; W. Li, Wadsworth Center / New York State Department of Health; K. Kannan, Wadsworth Center / New York State Department of Health / Division of Environmental Health Sciences*

The occurrence and profiles of 15 organophosphate flame retardants/plasticizers (3 chlorinated [Cl]-OPFRs, 3 aryl compounds, 9 non-Cl alkyl and other compounds) were investigated in indoor air and dust from various types of microenvironments (total n=64) in and around the Albany area of New York State. Indoor dust from the floor was collected from 3 houses and 3 fire stations to investigate partitioning characteristics of OPFRs/plasticizers between vapor phase and particulate phase of air and in dust. The total concentrations of organophosphate esters (OPEs) in bulk air were found at several tens to hundreds of ng/m3. Among the eight categories of microenvironments, samples collected from automobile parts shops contained the highest concentrations of OPEs in indoor bulk air (mean: 258 ng/m3), followed by electronics shops, nail salons and interior design shops. Daily intake of OPEs via the inhalation, dermal contact, and ingestion of indoor air/dust will be presented.

**WP090 An assessment of the exposure of the Irish population to selected brominated flame retardants via indoor air and dust**

*S.J. Harrad, The University of Birmingham; D. Drage, The University of Birmingham / School of Geography Earth and Environmental Sciences; M.A. Abdallah, University of Birmingham / Division of Environmental Health and Risk Management / College of Life and Environmental Sciences; N. Wemken, M. Coggins, National University of Ireland Galway*

This study assesses for the first time, exposure of the Irish population to polybrominated diphenyl ethers (PBDEs), hexabromocycododecane (HBCDD), and decabromodiphenyl ethane (DBDPE) in common indoor microenvironments. To do so, passive air sampler (PAS) and floor dust samples were collected from Irish homes, cars, offices and primary school classrooms (n=30 per microenvironment) between August 2016 and January 2017. PAS consisting of a sorbent (XAD-3) impregnated polyurethane foam disk (PUF) were deployed for 60 days, placed on elevated surfaces in homes, offices, and schools, and the floor behind the passenger or driver's seat in cars. Dust samples were collected by vacuuming floors following methods previously described. Concentrations in both air and dust of PBDEs and HBCDD in Ireland were of similar magnitude to those reported previously for the UK. In contrast, concentrations of DBDPE in air (median: 100 pg/m$^3$, range: 0.72-7000 pg/m$^3$) and dust (6900 ng/g; range: < 6.0 – 540000 ng/g) are to our knowledge the highest reported globally to date. These data suggest that DBDPE is being used substantially in Ireland.

**WP091 Analysis of Polybrominated Diphenyl Ether, Novel Brominated Flame Retardants and Organophosphate Flame Retardants in Dust from Canadian Fire Stations**

*F. Brown, D.H. Tarrant, R. Gill, J. Dhaliwal, California Environmental Protection Agency / Department of Toxic Substances Control / Environmental Chemistry Laboratory; R. Sarala, California Environmental Protection Agency / Environmental Chemistry Laboratory; S. Patton, Commonweal; J. Park, M. Petreas, California Environmental Protection Agency / Department of Toxic Substance Control / Environmental Chemistry Laboratory*

The long term and widespread use of flame retardants (FRs) such as polybrominated diphenyl ethers (PBDEs) and their replacements such as novel (non-PBDE) brominated flame retardants (NBFRs) and organophosphate flame retardants (OPFRs), as well as their potential for environmental and biological adverse effects, have been exhaustively documented. House dust is one matrix that contains very high levels of many persistent organic pollutants (POPs), including some of these FRs discussed above, and one source of house dust of particular interest is dust from the living quarters of fire stations. By nature of their jobs, firefighters are exposed to a wide variety of contaminants at fire events, which they can carry back to the station on their turnout gear. In addition, their living quarters contain the same products that civilians have in their homes (e.g., upholstered foam furniture, computers and other electronics), which also potentially contribute to high levels of FRs in dust. Thus, firefighters are exposed to these high levels of FRs, as biomonitoring studies have demonstrated. In coordination with the International Association of Fire Fighters (IAFF), vacuum cleaner bags from vacuums used to clean 24 fire station living quarters from four different Canadian provinces (British Columbia, Alberta, Manitoba, Ontario) were sent to our laboratory (2018), along with questionnaires regarding station characteristics, operations and practices. Contents were sieved and the fine fraction collected and used for analysis for: (1) PBDEs and NBFRs by high resolution GCMS; and (2) OPFRs by gas chromatography / tandem mass spectrometry (GC-MS/MS). Results from the Canadian samples are compared and contrasted with those obtained from our previous studies, including: (1) residential house dust collected from 204 Northern California homes (2001 – 2007, 2010); (2) dust from 20 Southern California fire stations (2010 – 2011); and (3) fire station dust from 25 fire stations (2015) from five different US states (California, Minnesota, New Hampshire, New York, and Texas). The views expressed are those of the authors and do not necessarily reflect the views of the State of California.

**WP092 Modelling the Fate of Organophosphate Esters in Toronto Stormwater**

*T.F. Rodgers, University of Toronto / Chemical Engineering and Applied Chemistry; E. Passeport, University of Toronto / Department of Civil and Mineral Engineering; M.L. Diamond, University of Toronto / Department of Earth Sciences*

Semi-volatile organic compounds (SVOCs) are a class of chemicals released in large quantities in urban areas from a variety of diffuse sources. The traditional focus of SVOC regulation has been for compounds which are persistent, bioaccumulative and have the potential for long range transport (PBT), which include polychlorinated biphenyls (PCBs), organochlorine pesticides and polybrominated diphenyl ethers (PBDEs). These compounds are generally hydrophobic and are therefore not typically found at high concentrations in surface waters. However, this is not the case with other SVOCs that are now receiving greater attention, some of which being used as replacements for the more traditional SVOCs as their usage is restricted through regulation. Reemtsma et al., (2016) have referred to these compounds as persistent mobile organic compounds (PMOCs) and have proposed mobility (M) as the new source of concern to replace "B" (bioaccumulation) in the persistent-bioaccumulative-toxic paradigm. Organophosphate esters (OPEs) are an example of SVOCs that could be considered as PMOCs. OPEs can be categorized into chlorinated compounds (Cl-OPEs), which are largely used as flame retardants, and non-chlorinated OPEs (non-Cl-OPEs) that are used as flame retardants and plasticizers. We investigated the transport and fate of OPEs through Toronto, Canada by modifying the Multimedia Urban Model of Diamond and Co-workers (2001) to better represent the transport and fate of PMOCs. Currently, we are developing a general model of contaminant fate in BCs, called the "Bioretention Blues" model, in order to investigate the efficacy of BCs for reducing loadings of PMOCs to surface water ecosystems using OPEs in Toronto as a case study. Our results indicated that stormwater is an important pathway by which OPEs enter surface water ecosystems, accounting for between 88-96% of loadings to nearshore Lake Ontario delivered by Toronto streams. Our results show that soil is effective in preventing >80% of loadings of non-Cl-OPEs through transformation, but was much less effective for Cl-OPEs, degrading < 20% of inputs to the soil while the rest entered either ground or surface water. These results show that BCs may be effective in mitigating the loadings of non-Cl-OPEs, but may be less effective for Cl-OPEs. Improvements to BC design, such as the use of organic capturing amendments, may be necessary to mitigate the loadings of Cl-OPEs and other PMOCs.

**WP093 Presence and distribution of 25 emerging flame retardants from five wastewater treatment plants in Canada**

*M. Woudneh, SGS AXYS Analytical Services, Ltd.; S. Smyth, Environment and Climate Change Canada; B. Chandramouli, SGS AXYS; C. Hamilton, SGS AXYS / Client Services; R. Grace, J. Cosgrove, SGS AXYS*

In this study, we report on the occurrence and phase distribution of a diverse suite of emerging non-polybrominated diphenyl ether (non-PBDE) flame retardants (FRs) in the liquid and solid waste streams of five wastewater treatment plants (WWTP) in Canada. The flame retardants studied included 6 dechlorane and related FRs, Di(2-ethylhexyl) tetrabromophthalate (BEHTBP), 2-Ethylhexyl 2,3,4,5-tetrabromobenzoate (EHTBB), 1,2-Dibromo-4-(1,2-dibromoethyl)cyclohexane (TBECH), 4 tribromophenyl ether and related FRs, and 12 monoaromatic FRs.. Influent, effluent and biosolid samples were collected from 5 WWTP in Canada. The samples were analyzed using liquid-liquid or liquid-solid extraction with liquid-liquid and gel permeation cleanups (GPC) and GC-(ECNI)-MS instrumental method. Distribution of the analytes dissolved in the aqueous phase and adsorbed to the solid phase were measured and their partitioning will be discussed. The measured values will also be compared to measured concentrations of organophosphate and PBDE flame retardants from the same treatment plants. This data contributes to our understanding of the occurrence, fate, behaviour and relative environmental significance of some of the important emerging flame retardants.

**WP094 Development and testing of a novel method to measure tetradecabromo-1,4-diphenoxybenzene in biosolid sludge from Canadian waste water treatment plants**

*K. Stroski, University of Manitoba / Chemistry; C.S. Wong, University of Winnipeg / Department of Chemistry; R.J. Letcher, Environment and Climate Change Canada / Ecotoxicology and Wildlife Health Division*

Tetradecabromo-1,4-diphenoxybenzene (tetradeca) is a highly brominated flame retardant which has been shown to degrade photolytically to produce lower brominated polybrominated-diphenoxybenzenes, compounds which show similar structural components of those reported as contaminants in the eggs of Great Lakes herring gull (*Larsus argentatus*). Currently there are no reports of tetradeca or its potential products in environmental samples including sediment in the Great Lakes area. Given the large size and hydrophobicity of tetradeca as well as its use in commercial flame retardant mixtures (SAYTEX 120), we hypothesize that biosolids from Canadian waste-water treatment plants (WWTPs) may be a sink for these compounds. The present study investigated tetradeca and some of its debrominated photolytic by-products in biosolid samples gathered from WWTPs that have previously shown to contain flame retardants. The biosolid samples were collected in 2014 to 2017 from 20 WWTPs serving urban centres across Canada. The biosolid samples were also from WWTPS differing in treatment type, including digestion (aerobic or mesophilic anaerobic), dewatering, alkaline stabilization and/or pelletization. A novel analytical method for measuring tetradeca on low-resolution mass spectrometry (MS) was adapted from a published high-resolution MS method while extractions utilized a Soxhlet extractor where previously accelerated solvent extraction was used. The newly developed method is more accessible to a wider range of laboratories, allowing further studies on tetradeca to be performed. This study represents to our knowledge the first look at tetradeca in biosolids and will in the future be expanded to previously gathered samples through time to generate potential temporal distribution of this compound in Canadian WWTPs.

**WP095 Relationships of polybrominated diphenyl ethers with algal organic matter and fatty acids in sediment cores, South China**

*Y. Huang, Guangzhou Institute of Geochemistry / Chinese Academy of Sciences / State Key Lab of Organic Geochem; Y. Ran, Guangzhou Institute of Geochemistry / Chinese Academy of Sciences*

The effects of algal organic matter (AOM), fatty acids (FAs), and climate change on the deposition history of polybrominated diphenyl ethers (PBDEs) in the subtropical lake and reservoir sediment cores, South China were investigated. The sedimentary fluxes of PBDEs were estimated. The results show that the patterns of PBDEs are dominated by BDE-209, followed by BDE-47, BDE-99, and BDE-183. Algae make a dominant contribution to the sedimentary organic matter. The downcore contents of PBDEs and AOM in these cores show decreasing trends. AOM contents are significantly related to PBDEs in the cores, indicating the importance of algal productivity. Contents of FAs in the meso-eutrophic reservoir cores are significantly correlated with those of AOM and PBDEs, further confirming the role of algae to the transfer and deposition of PBDEs. Climate warming is observed to enhance the algal productivity in the reservoirs, thus elevating the deposition of PBDEs. Finally, the fluxes of PBDEs in the meso-eutrophic reservoir and the oligotrophic reservoir are estimated to be 2.22 ng/cm$^2$ yr and 0.959 ng/cm$^2$ yr, respectively, which increase with the increasing trophic level.

**WP096 Short-, Medium-, and Long-Chain Chlorinated Paraffins in Wildlife from Paddy Fields in the Yangtze River Delta**

*X. Du, University of California, Riverside; Y. Zhou, Tongji University / Key Laboratory of Yangtze River Water Environment / Ministry of Education / College of Environmental Science and Engineering; Y. Qiu, Tongi University*

Short-chain chlorinated paraffins (SCCPs) were added to Annex A of the Stockholm Convention on Persistent Organic Pollutants in April, 2017. As a consequence of this regulation, increasing production and usage of alternatives, such as medium- and long-chain chlorinated paraffins (MCCPs and LCCPs, respectively), is expected. Little is known about the environmental fate and behavior of MCCPs and LCCPs. In the present study, SCCPs, MCCPs, and LCCPs were analyzed in nine wildlife species from paddy fields in the Yangtze River Delta, China, using atmospheric pressure chemical ionization-quadrupole time-of-flight mass spectrometry. SCCPs, MCCPs, and LCCPs were detected in all samples at concentrations ranging from < 91-43000, 96-33000, and 14-10000 ng/g lipid, respectively. Most species contained primarily MCCPs (on average 44%), with the exception of collared scops owl and common cuckoo, in which SCCPs (43%) accumulated to a significantly (i.e. $p< 0.05$) greater extent than MCCPs (40%). $Cl_6$ groups were dominant in most species except for yellow weasel and short-tailed mamushi, which contained primarily $Cl_7$ groups. Principal components analysis, together with CP concentrations and carbon stable isotope analysis showed that habitat and feeding habits were key factors driving CP accumulation and congener group patterns in wildlife.

### WP097 Organophosphate Ester Flame Retardants in San Francisco Bay

R. Sutton, San Francisco Estuary Institute; Y. Wu, Indiana University, Bloomington / Cooperative Wildlife Research Laboratory / Department of Zoology; D. Chen, Jinan University / School of Environment

As the largest estuary on the West Coast of the Americas, the San Francisco Bay drains approximately 40% of the state of California, and supports a dense local urban population. These features make the region an excellent laboratory for studies of anthropogenic contaminants. The Regional Monitoring Program for Water Quality in San Francisco Bay (RMP) supports strategic studies of contaminants of emerging concern (CECs) in the Bay, including monitoring of polybrominated diphenyl ether (PBDE) flame retardants and their alternatives. The results of a pilot study characterizing a broad array of flame retardants in multiple Bay matrices suggested organophosphate esters (OPEs) merit further study. OPEs are used as flame retardants and plastic additives and are water soluble. Some members of this class have predicted no effect concentrations (PNECs) less than 1 µg/L. Analysis of over a dozen OPEs in ambient Bay water samples collected in 2017 will be presented.

### WP098 Tissue-distribution and in-ovo maternal transfer of PBDEs and non-PBDE flame retardants in Great Lakes Herring Gulls

T.A. Smythe, Carleton University / Chemistry; L. Mattioli, R.J. Letcher, Environment and Climate Change Canada / Ecotoxicology and Wildlife Health Division

Herring gulls (*Larus argentatus*) of the North American Great Lakes are primarily consumers of the aquatic ecosystem, but are also opportunistic and will feed on terrestrial diet items. Herring gulls have been a sentinel species for long-term contaminant monitoring for the past 40 years. Conventional techniques of avian monitoring rely on the measurement of whole (i.e. homogenized) eggs or pools. Generally there are few studies that have examined the extent of the tissue-specific distribution of chemicals of emerging environmental concern (CECs), and the extent of maternal transfer from mother birds to their offspring *in ovo*. This study investigated the tissue-specific (i.e. liver, adipose, muscle, blood (plasma and red blood cells), and brain) distribution of polybrominated diphenyl ethers (PBDEs) and several non-PBDE flame retardants (FRs) in mother herring gulls from Chantry Island, Lake Huron, and the extent of *in-ovo* transfer to their eggs (i.e. yolk and albumen). Comparisons were made to the distribution profiles of per- and polyfluorinated alkyl substances (PFASs) and organophosphate esters (OPEs) previously measured in the same maternal gulls and eggs. The predominant BDE congeners in both herring gull tissues and eggs were BDE-47, -99, -100, -153, -154, and -209, while Dechlorane Plus isomers and hexabromocyclododecane (HBCDD) were the principal non-PBDE FRs. Total PBDE concentrations were > 10x higher than combined non-PBDE FR concentrations in all tissues, while rates of maternal transfer were similar (6-7%) for each compound. PBDEs and HBCDD showed similar concentrations in both gull red blood cells (RBCs) and plasma, in comparison to OPEs and PFASs, which preferentially accumulated in the RBCs and plasma, respectively. The extent of maternal transfer was substantially greater for PFASs (~80%), while OPE transfer was intermediate of the PFASs and PBDE/non-PBDE FRs. This is also the first known report on the presence of methoxylated polybrominated diphenoxy benzene contaminants in an animal body compartment (i.e. liver, muscle, and adipose) in concordance with previously reported measurements in Great Lakes herring gull eggs. These results emphasize the importance of understanding the distribution and extent of maternal transfer of CECs for future monitoring. For example, the low extent of maternal transfer for more highly brominated compounds may indicate that relying solely on egg measurements may underestimate total body burdens of birds.

### WP099 Prioritization of 10 organic flame retardants using an avian hepatocyte toxicogenomic assay

F. Page-Lariviere, S. Chiu, S.P. Jones, A. Farhat, D. Crump, J. O'Brien, Environment and Climate Change Canada / National Wildlife Research Centre

As the number of chemicals developed and used by industry increases, the inherent limitations of traditional toxicology approaches become an unavoidable issue. To help meet the demand for toxicity evaluation, new methods, such as high-throughput toxicity screening, are currently being developed to permit rapid determination of toxic, molecular and/or biochemical effects of a wide range of chemicals. In the present study, we demonstrate the utility of an avian in vitro toxicogenomics screening approach to determine the cytotoxic and transcriptomic effects of 10 organic flame retardants (OFRs) currently of international priority for ecological risk evaluation in order to prioritize and inform future toxicological studies. Hepatocytes from two avian species, chicken and double-crested cormorant, were prepared and exposed for 24 hours to various concentrations (0 to 300 µM) of OFRs among which were p-tert-Butylphenyl diphenyl phosphate (BPDP) and phenol, isopropylated, phosphate (3:1) (IPPP). Cell viability, the 7-ethoxyresorufin-*O*-deethylase (EROD) assay, and transcriptomic analysis using species-specific ToxChip PCR arrays were performed to evaluate the in vitro effect of these OFRs. Of the 10 OFRs assessed, BPDP and IPPP elicited the strongest cytotoxic and transcriptomic response in both chicken and double-crested cormorant hepatocytes and are therefore recommended as priority candidates for further toxicological investigations.

### WP100 Biomarkers responses in the fish *Prochilodus lineatus* after TCPP and TDCP exposure

M. Lauer, Universidade Estadual de Londrina / DCIF; C. Martinez, Universidade Estadual de Londrina / Ciencias Fisiologicas

Organophosphate flame retardants (OPFR) are widely used, are found in the environment and accumulate by the biota. The aim of this study was to evaluate the effects of TCPP and TDCP in the neotropical fish *Prochilodus lineatus*. Juveniles were exposed for 96h to 1.5 and 30 µg/L of TDCP, to 2 and 200 µg/L of TCPP, and to a mixture of 1.5 µg/L of TDCP and 2 µg/L of TCPP. A control treatment was also run. Gills and liver were removed for analysis of Glutathione S-transferase (GST) and ethoxyresorufin-O-deethylase (EROD) activities, and lipid oxidation levels (LPO) and GSH content. No mortality was observed. No statistical difference was observed in EROD and GST activity in the gills between treatments. EROD in the liver of animals exposed to the mixture of OPFR was higher than those of the animals exposed to only TCPP or TDCP, but no difference occurred in relation to the control animals. GST activity was inhibited in the liver of animals exposed to the mixture of OPFR in relation to the animals exposed to 30 µg/L of TDCP and TCPP, but there was no difference in relation to control animals. GSH content in the liver was not altered by OPFR exposure, but it was elevated in the gills of the fish exposed to the mixture in relation to those exposed to TDCP and 200 µg/L of TCPP. No lipid damage was observed after OPFR exposure. These results indicate that some biomarkers can be altered by OPFR exposure and that the exposure to the mixture of TCPP and TDCP caused more alterations than the exposure to TCPP and TDCP separately. More studies are necessary to establish the mechanism of toxicity of TCPP and TDCP to fish

**WP101 Tris (1,3-dichloro-2-propyl) phosphate exposure during gastrula induces anemia in zebrafish embryos**

*V. Cheng, University of California, Riverside / Environmental Toxicology Graduate Program; S. Dasgupta, University of California, Riverside / Department of Environmental Sciences; D.C. Volz, University of California, Riverside / Environmental Sciences*

Tris(1,3-dichloro-2-propyl) phosphate (TDCIPP) is a high-production volume organophosphate flame retardant commonly detected within indoor dust following migration from end-use products. Therefore, the potential for TDCIPP-induced developmental toxicity raises concern for pregnant women and children exposed through inhalation and ingestion of TDCIPP-contaminated dust. Within early zebrafish development, initiation of exposure to TDCIPP at 0.75 h post-fertilization (hpf) results in epiboly delays by 6 hpf, dorsalization by 24 hpf, and adverse effects on mesoderm-derived tissues by 72 hpf. Therefore, as red blood cells (RBCs) are derived from the mesodermal germ layer, the objective of this study was to determine whether initiation of TDCIPP exposure at 0.75 hpf results in adverse effects on RBC abundance by 72 hpf. Embryos were exposed to vehicle (0.1% DMSO), 0.047 µM butafenacil (an herbicide and potent inducer of anemia in zebrafish embryos), or TDCIPP (1.56 or 3.12 µM) from 0.75-72 hpf or 10-72 hpf, and 72-hpf embryos were fixed and stained with *o*-dianisidine to quantify hemoglobin as a read-out for RBC abundance. Initiation of TDCIPP exposure at 0.75 hpf resulted in a concentration-dependent decrease in hemoglobin abundance in the absence of gross malformations. However, initiation of exposure at 10 hpf significantly decreased the magnitude of effect on hemoglobin abundance at 72 hpf relative to initiation of exposure at 0.75 hpf, suggesting that the effect of TDCIPP on RBCs was dependent on exposure during gastrulation (~5-10 hpf) – a critical stage of embryogenesis that includes germ layer (e.g., mesoderm) development. Overall, our findings demonstrate that TDCIPP exposure during early embryogenesis results in anemia by 72 hpf – a phenotype that may be associated with TDCIPP-induced disruption of normal germ layer development.

**WP102 mRNA-Sequencing Identifies Liver as a Potential Target Organ for Triphenyl Phosphate in Embryonic Zebrafish**

*A. Reddam, C.A. Mitchell, S. Dasgupta, D.C. Volz, University of California, Riverside / Environmental Sciences*

Triphenyl phosphate (TPHP) is a commonly used organophosphate flame retardant and plasticizer in the United States. Over the past decade, there has been a marked increase in the use of TPHP due to the phase-out of certain brominated flame retardants. Using zebrafish as a model, previous studies have shown that TPHP exposure from 24 to 72 hours post fertilization (hpf) results in severe cardiac looping defects by 72 hpf – a phenotype that is dependent on exposure during pharyngula (24-48 hpf) and mitigated by pre-treatment with non-toxic concentrations of a pan-retinoic acid receptor (RAR) agonist (fenretinide). Therefore, the objectives of this study were to 1) rely on mRNA-sequencing to identify pathways before and after cardiac looping (30 and 48 hpf, respectively) that may be impacted following exposure to 10 µM TPHP from 24-48 hpf and 2) determine whether pre-treatment with 2 µM fenretinide from 24-30 hpf mitigates cardiotoxicity-related pathways within embryos exposed to TPHP from 30-48 hpf. Based on mRNA-sequencing, TPHP exposure from 24 to 30 hpf and 24 to 48 hpf significantly affected the abundance of 305 and 274 transcripts, respectively, relative to vehicle (0.1% DMSO) controls. In addition to minor effects on cardiotoxicity- and nephrotoxicity-related pathways, Ingenuity Pathway Analysis (IPA) of significantly affected transcripts from 30- and 48-hpf embryos revealed that hepatotoxicity-related pathways were strongly affected following exposure to TPHP alone. Moreover, while pre-treatment with fenretinide mitigated TPHP-induced cardiac looping defects at 72 hpf, IPA revealed that fenretinide was unable to block TPHP-induced effects on cardiotoxicity-, nephrotoxicity-, and hepatotoxicity-related pathways at 30 and 48 hpf. Overall, our mRNA-sequencing-based data suggest that, in addition to the heart, the embryonic liver may be highly susceptible to TPHP exposure during early development. Therefore, future research is needed to 1) confirm that TPHP exposure alters the normal trajectory of liver development (based on phenotypic data) within zebrafish embryos and 2) identify the mechanism of action that leads to potential TPHP-induced effects on hepatocytes within zebrafish and human cell-based systems.

**WP103 Tris(1,3-dichloro-2-propyl) phosphate (TDCIPP) exposure during early-blastula alters the normal trajectory of zebrafish embryogenesis**

*S. Dasgupta, V. Cheng, S. Vliet, C.A. Mitchell, D.C. Volz, University of California, Riverside / Environmental Sciences*

Tris(1,3-dichloro-2-propyl) phosphate (TDCIPP) is a high-production volume organophosphate flame retardant used around the world. Due to leaching from end-use products into indoor dust, concerns remain about the potential effects of TDCIPP on human populations, particularly during early development. Using zebrafish embryos, we previously showed that initiation of TDCIPP exposure at 0.75 h post fertilization (hpf) leads to defects in embryogenesis, marked by epiboly arrest (4-6 hpf) and dorsalization (24 hpf). Interestingly, at 24 hpf, TDCIPP-induced dorsalization phenocopied embryos exposed to the bone morphogenetic protein (BMP) pathway inhibitor dorsomorphin (DMP), suggesting that TDCIPP may have a similar target as DMP. Therefore, using a combination of mRNA sequencing, pharmacologic, and immunohistochemical strategies, our overall objectives were to investigate the impact of TDCIPP on BMP signaling and identify other potential targets and downstream effects. We first showed that embryos are most sensitive to TDCIPP-induced effects when exposed within early-blastula (2-3 hpf). We also found that pre-treatment with 4'-hydroxychalcone (a BMP agonist) significantly mitigated TDCIPP-induced deformities. However, phospho-Smad1/5/9 immunostaining revealed that DMP – but not TDCIPP – blocked normal BMP signaling gradient, suggesting that TDCIPP does not impact BMP signaling. Similarly, mRNA-sequencing data revealed that TDCIPP did not significantly affect transcripts involved in BMP signaling. Interestingly, at the beginning of segmentation (10-12 hpf), TDCIPP exposures resulted in a decrease in transcripts that regulate mesoderm differentiation (*tbx16, tbx6, tbx6l,* and *msgn1*). Indeed, Tbx16 immunostaining revealed that the mesoderm was disrupted in TDCIPP-treated embryos, resulting in less-developed mesoderm-derived structures (e.g., somites and notochord). We also found that TDCIPP affected development of red blood cells (which are also mesoderm-derived) and eye, with decrease in hemoglobin, eye area, eye pigmentation, and retinal neurons by 72 hpf. Overall, our results suggest that initiation of TDCIPP exposure during early-blastula alters the normal trajectory of early embryogenesis, leading to abnormal development of vital tissues and organs within the embryo. As early developmental processes are conserved across all vertebrates, our findings suggest that TDCIPP has the potential to induce similar effects following *in utero* exposure in mammals.

**WP104 Effects of a brominated organophosphate flame retardant on amphibians during their aquatic life stages**

*S.A. Robinson, S.D. Richardson, Environment and Climate Change Canada / Wildlife and Landscape Science; A. McFee, Carleton University / Biology; A.O. De Silva, Environment and Climate Change Canada / Aquatic Contaminants Research Division; V. Trudeau, University of Ottawa / Biology*

The transition from tadpole to frog (metamorphosis) and sex differentiation are tightly controlled by the endocrine systems including hormones. Exposure to even low concentrations of certain environmental contaminants can change normal hormone processes that can have severe effects on biological development and thus the production of healthy, reproductively capable individuals. We evaluated the sex-steroid and thyroid disrupting potential of a high-risk brominated organophosphate flame retardant identified on Canada's Chemicals Management Plan

(CMP) priority new substances list as a suspected endocrine receptor binder. We assessed the toxicity and tissue residues of the flame retardant, 2,2-bis-(bromomethyl)-3-bromo-1-propanol phosphate (multiple CAS: 19186-97-1, 134376-16-2, 36483-58-6; molecular formula: $C_{15}H_{24}Br_9O_4P$) in two Canadian native species, *Lithobates sylvaticus* and *L. pipiens*. This substance would be used in consumer products and primarily enter the environment via waste water treatment effluents and the application of biosolids. First, we conducted standard 96 h acute toxicity tests to establish lethal and sub-lethal acute effects. We then used this information to select sub-lethal concentrations for chronic exposures to *L. pipiens*. We determined the lethal concentration that resulted in 50% mortality and assessed for growth differences and malformations in hatchlings exposed to the flame retardant at concentrations up to 245 µg/L compared to controls. Finally, *L. pipiens* tadpoles were chronically exposed for 30-days to sub-lethal concentrations of this compound, and growth, developmental stage and sex differentiation were assessed. Our study supports the hazard profile risk assessment of a CMP3 priority new substance by providing some of the first aquatic vertebrate toxicity data for this compound.

**WP105 Environmentally relevant concentrations of Triphenyl Phosphate induced Gonadal Intersex and Changed Reproductive Behavior in Japanese Medaka**

*Y. Li, C. Wang, F. Zhao, S. Zhang, R. Chen, T. Yang, J. Hu, Peking University*

Triphenyl phosphate (TPhP) as a typical kind of organophosphorus flame retardants (OPFRs), has been frequently detected in surface water and wildlife. To evaluate the reproductive toxicity of TPhP for fish, we exposed Japanese Medaka (Oryzias latipes) from hatching to sexual maturity (100 dpf) at 134.1, 299.1, and 1429.5 ng/L, and it was found that TPhP could induce gonadal intersex of male medaka at the lowest concentration. Chasing time of male fish before mating was increased about 2-fold in 299.1 ng/L exposure group, and it was regulated by the ratio of estrogen and androgens. Successful mating rate was significantly reduced from 100% at control to 56.25% at 1429.5 ng/L. TPhP also decreased fertilization and hatching rates of eggs, and the lowest observable effective concentration (LOEC) of TPhP to significantly inhibit fertilization and hatching rates were 1429.5, and 299.1 ng/L, respectively. We first demonstrated that TPhP could cause problems in fish testicular development and reproductive behaviors at environmentally relevant concentrations.

## Fate and Effects of Chemicals from Diffuse Sources and Stormwater

**WP106 Investigation of hemolytic effects in coho salmon exposed to urban stormwater**

*S. Blair, Washington State University; C. Barlow, The Evergreen State College; J. McIntyre, Washington State University*

Coho salmon are uniquely sensitive to urban stormwater, as demonstrated in the recurrent acute mortality phenomenon affecting coho in urban Puget Sound lowland streams. Symptoms include increased surfacing and loss of equilibrium prior to death, suggesting that cardio-respiratory distress may lead to the acute mortality. Chemical toxicity is implicated because abiotic factors in urban streams such as dissolved oxygen and temperature are within levels that are safe for fish. Although the causative agents in stormwater runoff remain unknown, oxidative stress may result from mixtures of numerous anthropogenically-sourced pollutants, such as metals, pesticides, and polyaromatic hydrocarbons. An oxidative stress mediated disturbance may be particularly damaging to circulating red blood cells, resulting in hemolysis. In the current study, we assessed indicators of intravascular hemolysis in juvenile coho exposed to highway runoff. Free hemoglobin released into the blood plasma due to acute and chronic hemolysis has been linked to numerous vascular abnormalities in humans and may therefore offer a potential pathway for cardio-respiratory distress in coho suffering from severe oxidative stress.

**WP107 Urban stormwater runoff causes cardiac injury in forage fish embryos**

*L. Harding, University of Washington / Aquatic and Fishery Sciences; M. Tagal, N. Scholz, J. Incardona, NOAA Fisheries / Northwest Fisheries Science Center; J. McIntyre, Washington State University*

Non-point source pollution, including untreated urban runoff, is the foremost water quality threat to aquatic habitats throughout the United States. In the Pacific Northwest, the impacts of toxic stormwater have been extensively studied for Pacific salmon and their prey. However, comparatively little is known about the vulnerability of marine forage fish such as Pacific herring (*Clupea pallasii*) and surf smelt (*Hypomesus pretiosus*). These keystone species spawn adhesive eggs on intertidal and shallow sub-tidal substrates, in close proximity to land-based runoff. To examine the impacts of stormwater runoff on forage fish embryonic development, we exposed herring embryos to 0, 12, 25, or 50% stormwater runoff beginning just prior to the onset of a visible heartbeat (5 dpf) through hatching (11 dpf). Embryos exposed to stormwater runoff accumulated up to 74 ng/g total polycyclic aromatic hydrocarbons (PAHs) including high levels of phenanthrene, pyrene and fluoranthene. Consistent with PAH exposure, *cyp1a* mRNA levels were significantly upregulated in embryos exposed to at least 12% stormwater for 2 or more days. Stormwater exposure caused significant reductions in larval length and eye size, suggesting developmental delay or reduced growth. In addition, herring exposed to stormwater runoff exhibited cardiac injury including both functional (e.g., altered contractility) and morphological (e.g., decreased ventricle area and altered ventricle shape) heart defects. In summary, stormwater runoff increased *cyp1a* mRNA expression, reduced embryonic growth and induced cardiac injury in Pacific herring embryos. These effects are remarkably consistent with the cardiac injury phenotype observed in oil-exposed fish and could result in delayed adverse outcomes such as reduced cardiorespiratory fitness and subsequent mortality.

**WP108 Tire dust toxicity on aquatic invertebrates**

*C. Duchet, Washington State University / Department of Evolutionary & Environmental Biology; B. Leonard, Washington State University, Puyallup; J. Prat, WSU / Puyallup Research & Extension Center; J.D. Stark, Washington State University / Dept of Entomology; J. McIntyre, Washington State University*

Road runoff contributes in large part to the total pollutant budget of receiving waters. Besides combustion engine emissions, brake and tire wear are major contributors to traffic-related particulate matter. Tire particulate waste released into the environment per capita is estimated at 0.81 kg/year. Tire dust has a complex chemical composition and some of its components are water soluble. During rain events chemicals from tire dust can be leached into stormwater runoff. Coho salmon (*Oncorhynchus kisutch*) are acutely sensitive to chemicals that leach from tires. A laboratory study was conducted to compare the acute sensitivity of coho salmon to that of sensitive aquatic invertebrate, the crustacean *Ceriodaphnia dubia*. A tire dust mix was made by grinding nine different tires (new and used) from light duty vehicles. A 10 g/L tire leachate was produced using a closed recirculating system, allowing water to run through the tire dust mix for 24 h. The eluate was tested at 1%,10%, 20%,100% concentrations to assess the toxicity of tire dust on the survival of *C. dubia* at 48 h and on the reproduction after 8 days of exposure. Whereas tire leachate was acutely lethal to coho salmon at 0.1 g/L ($LC_{50}$), the $LC_{50}$ for *C. dubia* was approximately 10-fold higher. Reproductive endpoints were the most sensitive to tire mixture leachate. Although *C. dubia* is widely considered a highly sensitive organism, this study demonstrates the variability in organismal response to constituents of road runoff and highlights that relying on one single-species test may not be representative.

**WP109 Assessment and management of stormwater impacts on sediment recontamination: You don't need to measure everything, just the right things**

*I. Drygiannaki, Texas Tech University / Department of Civil Environmental and Construction Engineering; B. Anandha Rao, Texas Tech University / Civil and Environmental Engineering; D. Athanasiou, Texas Tech University / Civil, Environmental, and Construction Engineering; M. Rakowska, National Research Council of the National Academies/USEPA / AED / Civil and Environmental Engineering; D.D. Reible, Texas Tech University / Civil and Environmental Engineering; G. Burton, University of Michigan / School for Environment and Sustainability; B. Chadwick, SPAWAR Systems Center Pacific / Environmental Sciences; G.H. Rosen, SPAWAR Systems Center / Energy and Environmental Sustainability; M. Colvin, SPAWAR Systems Center Pacific / Energy and Environmental Sustainability; R. Pitt, The University of Alabama; E. Strecker, B. Steets, M. Otto, Geosyntec Consultants*

Stormwater sources are difficult to understand because of the poor characterization of the irregular, event-driven inputs and the difficulty of managing diffuse sources of large volumes of runoff. The study objective is to develop methodologies to quantify the consequences of ongoing low-level sources on chemical concentrations, contaminant availability, and effects on biological receptors in surficial sediments. The study area was in Paleta Creek near Naval Base San Diego (NBSD), in California. Two storm-events were captured for particle size characterization and chemical analysis. Receiving and outfall waters collected using auto-samplers, which were triggered at each location during two different seasons. The samples were analyzed for a variety of metals, PAHs, and PCBs, as a function of particle size. Sediment traps and sediment cores were also collected from the Creek and subjected to bulk chemical analysis. The fractionated water and sediment samples were processed for metal extraction using the modified EPA method 3005A and 3050B, respectively, and were analyzed using ICP-MS and MERX-T. Persistent organic pollutants in water samples were Liquid-Liquid Extracted (LLE) using the modified EPA Method 3510C, while sediment was extracted by Pressurized Fluid Extraction (PFE with ASE 350) using the modified EPA Method 3545A. PAH analysis was performed on HPLC and PCBs on GC/MS. Results showed that storm-events were dominated by coarse particles initially most likely to lead to sediment recontamination in the near field of the receiving water (e.g., PAH, and Cd). Cu was associated to the dissolved and clay fraction, however the depositing loads were more influenced by resuspension and redistribution of sediment than stormwater. Data suggested that PAHs and PCBs, due to low bioavailability as determined with passive sampling and bioaccumulation testing, are not a strong contributor to sediment toxicity which appeared to be better correlated to the presence of pyrethroids in the traps. The study indicated that the size-segregated contaminant loads and simultaneous receiving water measurements were very helpful in relating the stormwater discharges to sediment recontamination. The particle associations in stormwater along with spatial distribution particularly in sediment traps, and less in the sediment cores, can identify contributing locations, effective remedial approaches, and help to propose best practices for stormwater and sediment management.

**WP110 Characterizing water quality background concentrations of aluminum, PCBs, and radioactivity on the arid Pajarito Plateau, New Mexico**

*B.G. Church, S.A. Tobiason, Windward Environmental LLC; A.B. White, E.M. Day, S.J. Veenis, A.R. Groffman, D.J. Carlson III, Los Alamos National Laboratory*

If NPDES permit action levels are set near or below background concentrations, achieving compliance is difficult or impossible and might serve only to attempt to reduce naturally occurring constituents. In regard to a NPDES stormwater permit for Los Alamos National Laboratory (LANL), which is situated on the arid Pajarito Plateau near Santa Fe, New Mexico (NM), studies show that aluminum and gross alpha radiation concentrations are attributable to Bandelier tuff, the major geologic media in the area. Meanwhile, atmospheric deposition of polychlorinated biphenyls (PCBs) contributes to an anthropogenic baseline, measurable in reference watersheds. As a result, exceedances of NPDES permit action levels and state water quality criteria (WQC) for these constituents are erroneously attributed to LANL discharges. To address this situation, a framework was established to generate water quality background threshold values (BTVs) that characterize natural background (NBG), anthropogenic baseline, and developed background conditions using statistical methods. Water quality data were evaluated for potential spatial and temporal dependencies, as well as relationships with suspended sediment concentration (SSC), a parameter positively correlated with storm water runoff. Data were stratified or normalized to SSC to address dependencies prior to calculating BTVs for 18 constituents, resulting in a total of 43 BTVs. A subset of those BTVs are discussed herein. Most BTVs were calculated using ProUCL as 95-95 UTLs based on gamma, lognormal, normal, or nonparametric methods. The resulting anthropogenic baseline PCB BTV of 0.058 µg/L is 90 times higher than the NM human health WQC (0.00064 µg/L). The NBG gross alpha BTV is 190 pCi/g SSC, which, after back-transformation using the 25$^{th}$ and 75$^{th}$ percentile of NBG SSC, ranges from 170 to 1,900 pCi/L, well above the NM WQC (15 pCi/L). Two NBG aluminum BTVs were developed (for subareas of Pajarito Plateau) of 17 and 76 mg/g SSC, which, after back-transformation, range from 15 to 1,700 mg/L and 68 to 78 mg/L, respectively; these values are much higher than the NM hardness-based WQC (ranging from 0.37 to 1.9 mg/L as total aluminum). These results suggest that BTVs should be taken into account before concluding that exceedances of state WQC and related LANL NPDES permit action levels are attributable to LANL discharges, leading to unwarranted actions such as engineered controls, 303(d) listings, and developing TMDLs.

## Alternative Animal Ecotoxicity Testing: New and Novel Approaches for Predicting Environmental Hazards and Risk Assessment

**WP111 Evaluation of Cu and CuO nanoparticle environmental impacts using laboratory small-scale microcosms**

*F. Wu, L. Crandon, Oregon State University; B.J. Harper, S.L. Harper, Oregon State University / Department of Environmental and Molecular Toxicology*

Copper based nanoparticles (NPs) are widely used in industrial and commercial products as sensors (49%), catalysts (20%), surfactants (6%), antimicrobials (4%), and for other purposes (21%). The high production volume and increasing use of copper-based NPs make the ecological risk of metallic copper or copper oxide (Cu and CuO) NPs a concern. The physico-chemical properties of copper-based NPs can impact their dissolution and aggregation behavior with concomitant impacts on their environmental toxicity. Here, we investigated NP dissolution, organismal uptake and aquatic toxicity of Cu, CuO NPs at 0, 0.1, 1, 5 or 10 mg Cu/L using a previously developed 5-day multi-species microcosm comprised of algae (*C. reinhardtti*), bacteria (*E. coli*), crustaceans (*D. magna*), and zebrafish (*D. rerio*). We hypothesized that Cu and CuO NPs can elicit differential toxicity to the organisms due to alterations in the bioavailability of dissolved copper species and variations in organismal nanoparticle uptake. The actual concentrations of dissolved Cu released from the NPs were compared to $CuCl_2$ ionic controls at the same concentrations to determine the relative contribution of particulate and dissolved Cu on organism uptake and toxicity. We found that both NPs had higher uptake in *D. magna* and zebrafish than equivalent ionic exposures, suggesting that both Cu-based NPs are taken up by organisms. Cu NP exposures significantly inhibited algal growth rate, *D. magna* survival, and zebrafish hatching while exposure to equivalent concentrations of $CuCl_2$ and CuO NPs did not. This indicates that Cu NPs themselves likely elicited particle-specific toxicity to the tested organisms. The increased potential of Cu relative to CuO NPs to generate reactive oxygen species could have contributed to the differential toxicity observed. Overall, this work was the first study to utilize a rapid assay design to evaluate the fate and eco-toxicological impacts of Cu and CuO NPs in an aquatic community.

**WP112 Inflammation of gill epithelia in fish causes increased permeation of polar organic chemicals via disruption of tight junctions**

*U. Fuchylo, University of Saskatchewan / Toxicology Centre; M. Brinkmann, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre; H. Alharbi, University of Saskatchewan / Toxicology Centre; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre*

In fish, the gill epithelial layer controls paracellular permeation of chemicals through epithelial tight junctions. Previous research has indicated that the integrity of epithelial tight junctions can be adversely impacted by gill inflammation. A loss of junction integrity could lead to greater uptake of harmful contaminants, effectively increasing their toxicity. In this study we investigated if inflammation could induce disruption of tight junctions in fish gill epithelia, and if this in turn increases passive transport of chemicals across the epithelia. Inflammation was experimentally induced in a permanent rainbow trout gill cell line (RTgill-W1) through exposure to non-cytotoxic concentrations of lipopolysaccharide (LPS). Transepithelial electrical resistance (TEER) was used to indicate epithelial tight junction integrity. Cells were also co-exposed to LPS and oil sands process-affected water (OSPW) to determine if the hypothesized reduction in tight junction integrity would result in greater transport of OSPW across the gill cell epithelial layer in vitro. Quantitative real-time PCR (qPCR) was carried out to characterize changes in transcript abundance of genes responsible for tight junction proteins (e.g. claudins). Cells exposed to LPS showed significant reduction in TEER after 24 h of exposure. qPCR data showed that the abundance of transcripts of genes coding for tight junction proteins (i.e. Claudin 28b and 10e) were significantly decreased in cells exposed to 20, 50, and 100 mg/L LPS. Furthermore, chemical analyses revealed a significant increase in transport of constituents of OSPW across the gill cell epithelial layer at all concentrations of LPS. These in vitro findings were confirmed by *a*n in vivo exposure experiment with fingerling rainbow trout that showed a comparable increase in OSPW content in fish exposed to both LPS and OSPW for 48 h, compared to fish exposed to OSPW alone. These results indicate that fish living in environments high in pathogens could be at risk of greater uptake of contaminants of environmental concern (i.e. chemicals in OSPW) than previously thought. This in turn highlights the need to further assess the risks that exposure to pathogens may pose from a toxicological perspective.

**WP113 Ecological Threshold for Toxicological Concern (eco-TTC) – Applications for Environmental Risk Assessment in Various Contexts**

*M.R. Embry, Health and Environmental Sciences Institute (HESI); M.G. Barron, USEPA / Gulf Ecology Division; A. Beasley, The Dow Chemical Company / TERC; S.E. Belanger, The Procter & Gamble Company / Central Product Safety Dept; M.A. Bonnell, Environment and Climate Change Canada / Ecological Assessment Division; J. Brill, The Procter & Gamble Co. / Environmental Stewardship and Sustainability; D. Chang, USEPA / OCSPP / OPPT / RAD; K.A. Connors, The Procter & Gamble Company / Environmental Stewardship and Sustainability Organization; D. De Zwart, DdZ Ecotox / Centre for Sustainability Environment and Health; M. Halder, European Commission Joint Research Centre / DG Joint Research Centre IHCP EURL ECVAM; S.A. Hughes, Shell Health – Americas / Shell Health Risk Science Team; A. Kienzler, European Commission – Joint Research Centre / DG Joint Research Centre IHCP EURL ECVAM; T.J. Norberg-King, USEPA / NHEERL / Mid-Continent Ecology Division; R.R. Otter, Middle Tennessee State University / Biology; H. Sanderson, Aarhus University / Environmental Science; P.W. Wilson, Sanofi U.S., Inc. / Health, Safety and Environment*

The Threshold for Toxicological Concern (TTC) is well-established for assessing human safety but has only recently been explored in the ecological context. Ecological TTCs (eco-TTCs) summarize the wealth of ecotoxicological information as Predicted No-Observed Effect Concentrations (PNECs) on diverse chemical substances in the form of probability distributions. These enable the prediction of untested chemicals based on a structural attribute, mode of action, or functional use. The approach may be useful to assess chemicals at early tiers of the risk assessment process, providing hazard perspective on chemicals that lack QSARs, guiding product development discussions, and assisting read across or category justifications. A database was developed based on recent assessments of published data and international chemical management programs. This data is associated with physical chemistry data and curated taxonomic information for the organisms tested, including a process to conclude acute and chronic effects as well as identify the PNEC for exposed ecosystems based on depth and breadth of data. Several mode of action schemes are also included to facilitate development of a best approach for grouping compounds. To make these data accessible and useful, the dataset was transitioned into a MySQL format, allowing for a format that is relational and scalable, facilitating easy access, sharing, and integration with other datasets and tools. The dataset is accessed via a web-based query system that is integrated with a PNEC calculator and probability distribution tools. The interface allows users to explore the data, upload additional datasets, derive threshold values based on specific criteria, and explore use and application of the eco-TTC concept. A workshop was held to discuss and evaluate the feasibility of the approach, including evaluation of several case-studies based on particular decision-contexts (e.g., prioritization and screening, chemical risk assessment, site specific risk assessment, mixtures, product development, criteria development). The discussions and conclusions will be presented, including exploration of how this approach could be applied and integrated into evaluation strategies. *The views, conclusions and recommendations expressed in this article are those of the author and do not necessarily represent views or policies of the European Commission, Environment and Climate Change Canada, or the U.S. Environmental Protection Agency.*

**WP114 Estrogenic effects of thyroid hormone disruption in zebrafish**

*R. Kim, J. Park, Korea Institute of Toxicology*

Thyroid hormones have been implicated in many physiological actions, such as metabolism, development, growth, and reproduction. The influences of thyroid hormone in gonadal development has been intensively studied in rodent species, and recently several studies in fish have highlighted the effect of reproduction by thyroid hormone disruption. We investigated the reproductive effects by thyroid hormone disruption in transcriptomic levels. Exposure of 3,5,3'-triiodo-l-thyroxine (T3, 1 nM) or propylthiouracil (PTU, 10 uM) to zebrafish induced estrogenic effect by regulating some key genes involved in steroidogenesis (estrogen production) and progesterone-mediated oocyte maturation pathway, including estrogen receptor (esr1 and esr2b) and vitellogenin (vtg1 and vtg2). by analyzing these molecular biomarkes, is information, suspected thyroid hormone disrupting chemicals, bisphenol S (BPS), tris (1,3-dichloro-2-propyl) phosphate (TDCPP), and di-(2-ethylhexyl)-phthalate (MEHP) were evaluated in the reproductive effects and found out that only MEHP showed distinct changes in these gene expression, which might be from thyroid hormone disruption. However it is necessary to evaluate qualitative and quantitative evidence of thyroid hormone disruption in zebrafish prior to conclude the association of thyroid hormone disruption caused by MEHP with the estrogenic effects. This study could provide important information on the reproductive toxicity caused by internal thyroid hormone disruption and also contribute to find novel biomarker(s) for screening estrogenic effect by chemicals that could cause thyroid hormone disruption.

**WP115 Application of Adverse Outcome Pathways to Non-Chemical Stressors: Examples assessing Sea Lamprey Parasitism and Warmed Winter Water Temperatures**

*T. Firkus, C.A. Murphy, Michigan State University / Department of Fisheries and Wildlife*

The adverse outcome pathway (AOP) concept is designed to describe a mechanistic-based progression from a molecular initiating event to an adverse outcome based on a perturbation from a chemical stressor. Although the AOP framework has gained considerable traction among toxicologists, its acceptance and use is limited. The inclusion of non-chemical stressors into the AOP framework has potential to broaden its applicability by creating a unified system through which interactions between chemical-based and ecology-based stressors can be assessed. This integrated system may improve the robustness of AOP networks and add credibility to adverse outcome pathway-based regulatory decision making and risk assessment. Non-chemical stressor based AOP development will require several small changes to the AOP framework such as allowing for initiating events at non-molecular levels of organization. We illustrate potential avenues for AOP development by incorporating two non-chemical stressors that include mechanical and thermal stressors. The first describes how epithelium loss from sea lamprey (*Petromyzon marinus*) parasitism leads to decreased sperm quantity and quality in a host lake trout (Salvelinus namaycush). The second describes how warmed winter water temperatures initiate early reproductive development leading to reproductive dysfunction during the normal spawning period. Expanding the AOP framework to include non-chemical stressors may improve AOP network development, contribute to quantitative AOP development, and will entice other disciplines to be involved and apply the AOP framework to their study systems.

**WP116 Development of a Novel Cell-Based Model for Assessing Potential Toxicity of Seafood Through Bioanalytical Tools**

*G.E. Sutherland, M.E. Franco, Baylor University / Department of Environmental Science; Z.C. Winfield, Baylor University; S. Usenko, R. Lavado, Baylor University / Environmental Science*

The health benefits of a diet high in fish are well-known, but unfortunately there are also significant health concerns associated with eating fish exposed to a variety of contaminants. Methylmercury, PCBs, and Dioxins are currently considered by many states for seafood consumption advisories; however, there is little known about the risks of many other chemicals now routinely detected in fish. With a growing need to reevaluate the compounds being considered in fish consumption risk assessments and subsequent consumption advisories, the need for a method of determining mechanisms of toxicity associated with seafood consumption is ever-present. The current study utilizes in vitro systems to model the human dietary pathway in a co-culture model to facilitate the identification of contaminants driving adverse biological responses. To reproduce the complexity and cellular interplay that occurs in the digestive system, the current study uses an intestinal cell model, the human adenocarcinoma Caco-2 cell line that spontaneously differentiates in vitro, expressing several morphological and functional characteristics of mature small intestinal enterocytes. For the liver, human HepaRG cells were used, which can undergo a complete hepatocyte differentiation program. HepaRG cells express high functional levels of most of the major xenobiotic metabolizing cytochrome P450s (CYPs), most of which are poorly expressed or not inducible in other liver cell lines. Intestinal Caco-2 cells were cultured on a transwell insert, with hepatic HepaRG cells cultured underneath, replicating the natural flow in digestive movement, and allowing for metabolic activity to take place. Chemical extractions were conducted utilizing fish and oyster standard reference material (SRM) from the National Institute of Standards and Technology (NIST). Dosing of this extract to the digestive co-culture model has shown cytotoxic effects, and further analysis of CYP induction and quantification of oxidative stress is described. These bioanalytical tools are used to identifying significant biological responses that are outside the predicted effect level of current screening advisories, and can help in supporting revisions of current regulations to protect human health.

**WP117 Quantitative ability of the CALUX assay for simple environmental extracts: A case study with estrone-spiked pond water**

*J.C. Brennan, R.W. Gale, J.K. Leet, D.E. Tillitt, USGS / Columbia Environmental Research Center*

Chemically-activated luciferase expression (CALUX) cell bioassays are relatively inexpensive, internationally utilized screening tools for various types of environmental pollutants such as dioxin-like chemicals (DLCs) or endocrine active substances (EAS). The dioxin CALUX cell bioassay is one of two U.S. Environmental Protection Agency-approved methods for quantifying levels of DLCs in many different sample types (the other method being gas chromatography-high resolution mass spectrometry [GC-HRMS]). However, CALUX assays are more problematic for quantifying levels of EAS due to the greater complexity of endocrine-active pathways in comparison to the well-characterized biochemical pathway and chemistry for DLCs. Nevertheless, many studies report estimates of ‘estrogen equivalents’ (EEQs) in complex samples and may compare these values to levels of estrogens detected by analytical chemistry methods (such as liquid chromatography quantitative time-of-flight MS [LC-QTOF-MS]). For complex samples such as environmental water or sediment, the EEQ values obtained by LC/MS often underestimate those generated by EAS assays. For simple samples, however, we explored the suitability of estrogen CALUX bioassays for quantitative purposes in water samples from laboratory studies. A series of control, estrone (E1), and E1/atrazine-spiked water samples for an in vivo fish exposure study was quantified with LC-QTOF-MS and analyzed with two estrogen CALUX cell bioassays, the OECD-approved VM7Luc4E2 cell bioassay and the VM7LucERbc9 cell bioassay (which is the VM7Luc4E2 cell line stably transfected with estrogen receptor beta). A method for screening environmental samples in 384-well plates was established in our laboratory for both of the estrogen CALUX cell bioassays with minimum detection limit (MDL) and half-maximal activity ($EC_{50}$) values of approximately 0.02-0.07 pg E1 and 0.24-0.28 pg E1, respectively. Concentrations of E1 in water as determined by LC-QTOF-MS were approximately 1 ng/L in the control tanks, 10-100 ng/L in the dosed tanks, and 10 mg/L in spiked water. Levels of E1 in water samples were then compared to those generated by the estrogen CALUX assays. This information can be used to strengthen laboratory exposure studies, demonstrating further utility of the CALUX assays.

**WP118 EcoToxChip: A toxicogenomics tool for chemical prioritization and environmental management (24 month update)**

*N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre; D. Crump, Environment and Climate Change Canada / National Wildlife Research Centre; J. Head, McGill University / Natural Resource Sciences; N.S. Hogan, University of Saskatchewan / Department of Animal and Poultry Science and Toxicology Centre; J. Xia, McGill University; G. Hickey, McGill University / Macdonald Campus / Natural Resource Sciences; S. Maguire, McGill University / Desautels Faculty of Management*

Our Large-Scale Applied Research Program (LSARP) grant from Genome Canada aims to develop, test, validate, and commercialize quantitative PCR arrays (EcoToxChips) and a data evaluation tool (EcoToxXplorer.ca) for the characterization, prioritization, and management of environmental chemicals and complex mixtures of regulatory concern. In Project Phase 1, EcoToxChips will be developed for laboratory model species representing the most important vertebrate groups in ecological risk assessment (fish-fathead minnow; bird-Japanese quail; amphibian-*Xenopus laevis*). Model species (adult and early-life stage, ELS) will be exposed via standardized tests to 8 environmental chemicals representative of natural resource/environment sectors of Canadian concern and also ones that impact a wide biological space (EE2, chlorpyrifos, benzo(a)pyrene, lead, fluoxetine, selenomethionine, trenbolone, HBCD) (Activity 1). An integrative systems approach based on functional ‘omics (combined global transcriptomic and proteomic profiling, targeted metabolome) and physiological analyses across levels of biological organization will then be applied to characterize relevant toxicity pathways including adverse outcome pathways, AOPs (Activity 2); from this, and other resources, species-specific EcoToxChips consisting of 384 environmentally-responsive genes of regulatory concern will be informed, built, tested, and optimized (Activity 3). EcoToxChip performance will be validated (and further optimized) through an inter-lab study with our collaborators (Activity 4). Under Activities 5-7, knowledge from Phase 1 will be translated to 3 native species (i.e., fish: rainbow trout; bird: double-crested cormorant; amphibian: wood frog). EcoToxXplorer.ca will provide intuitive bioinformatics support and be modeled on our successful cloud-based tools (metaboanalyst.ca). To position the team advantageously with regard to the commercialization and institutionalization of the deliverables, our GE3LS research will produce and leverage social science knowledge about the phenomenon of "institutional entrepreneurship". The anticipated socioeconomic benefits associated with the adoption of our deliverables, namely more focused animal testing, improved regulatory decision-making, and cost-efficiencies. Here we provide a 24 month update of our project (www.ecotoxchip.ca).

**WP119 Design thinking to inform micro-level features of the EcoToxChips and EcoToxXplorer.ca**

*N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences; J. Ewald, McGill University / Macdonald Campuss / Natural Resource Sciences; G. Pain, McGill University / Desautels Faculty of Management; D. Crump, Environment and Climate Change Canada / National Wildlife Research Centre; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre; J. Head, McGill University / Natural Resource Sciences; N.S. Hogan, University of Saskatchewan / Department of Animal and Poultry Science and Toxicology Centre; J. Xia, McGill University; G. Hickey, McGill University / Macdonald Campus / Natural Resource Sciences; S. Maguire, McGill University / Desautels Faculty of Management*

Our Large-Scale Applied Research Program (LSARP) grant from Genome Canada aims to develop, test, validate, and commercialize quantitative PCR arrays (EcoToxChips) and a data evaluation tool (EcoToxXplorer.ca) for the characterization, prioritization, and management of environmental chemicals and complex mixtures of regulatory concern. To help ensure that project deliverables are adopted by end-users, the objective of this work was to incorporate design thinking into the development of the EcoToxChips and EcoToxXplorer.ca. This product design methodology includes 6 steps: 1) Collect data to understand users; 2) Determine how to address users' issues; 3) Generate product ideas; 4) Build product prototypes; 5) Test prototypes; and, 6) Make product. Key activities, outputs, and outcomes were discussed as they pertain to "micro-level" design of the project deliverables. First, a process was established to solicit information from user groups as to the relevance and importance of specific design features. This activity resulted in a 'registry' within which information from 26 informants has been collated to date. Second, with key insights extracted from each interviewee, an inventory of use cases (chemical screening and prioritization; hazard identification/MOA; environmental monitoring) and specific user-journeys (evaluating new chemicals; industry R&D; Great Lakes monitoring) were built to help focus the design of our deliverables. Third, a divergent and convergent phase ensued to help narrow down a set of deliverable features and detail how they may be realized. Finally, prototypes of the EcoToxChip (e.g., 384 well plate with ~30 QC genes and ~350 target genes organized into ~25 toxicity modules, etc…) and the EcoToxXplorer.ca (e.g., cloud-based tool with 3 main components being data upload and QC, statistical and functional analysis, report generation) were developed, and are now being deliberated upon by project team members, collaborators and end-users. To leverage iterative consultations with stakeholders, the most updated prototypes will be presented at SETAC for the at-large community to comment upon, before we launch manufacturing of the EcoToxChips, and continue programming of the EcoToxXplorer.ca.

**WP120 BE-SPME as a predictive screening tool for exposure to petroleum substances in the fish embryo toxicity test (OECD 236)**

*B. Hedgpeth, A.D. Redman, ExxonMobil Biomedical Sciences / Toxicology and Environment Science Division; R.A. Alyea, ExxonMobil Chemical Company / Marine Science Institute; J. Butler, ExxonMobil Research Qatar / Environmental Toxicology and Chemistry Laboratory; M. Lampi, ExxonMobil Biomedical Sciences, Inc. / Toxicology & Environmental Sciences*

The success of the OECD 236 fish embryo test suggests potential utility in animal alternative testing. The objectives of the present study were to characterize the sensitivity of sublethal endpoints in the OECD 236 tests relative to other aquatic species following exposures to petroleum substances. A biomimetic solid-phase microextraction method was employed to measure total bioavailable hydrocarbons as a common exposure metric across compositionally distinct test substances. Results indicate that sublethal endpoints occurred just prior to lethality, though no one phenotype was consistently more sensitive than another. Additionally, whole transcriptome microarray was used to observe the transcriptome profile of developing zebrafish in response to similarly classed test substances. The transcriptome profile was compared amongst test substances as well as between test substance treatments. Using the sublethal morphological threshold established prior, we explored the transcriptome profile of embryos which displayed morphological alterations and embryos which appear to be normal, providing insight into limitations of biological response which precede morphological alterations.

**WP121 Kinetics of Glutathione Depletion and Antioxidant Gene Expression as Indicators of Chemical Modes of Action Assessed in Two In Vitro Models**

*F. Melnikov, Yale University / School of Forestry and Environmental Studies; D. Botta, University of Washington / Environmental and Occupational Health Sciences; A. Voutchkova-Kostal, George Washington University / Chemistry; P. Anastas, Yale University / Department of Chemistry; J. Kostal, The George Washington University / Chemistry; T. Kavanagh, University of Washington*

Here we report a vertically integrated in vitro – in silico study that used seven diverse chemicals (cumene hydroperoxide, t-butyl hydroperoxide, hydroquinone, t-butyl hydroquinone, Bisphenol A, Dinoseb, and peflourooctanoic acid) suspected of inducing OS to probe the relationship between chemical properties, antioxidant gene expression, glutathione (GSH) depletion, and viability effects. Concentration-depend viability effects were assessed by MTT assay in two Hepa-1 liver cell line: a control cell line and a transfected line with increased glutamate-cysteine ligase (GCL) activity and GSH content. Change in of *Gclc*, G*clm*, *Hmox*, and *Nqo1* gene expression and intracellular GSH content in response to sublethal chemical exposure in both cell lines were monitored by RT-qPCR and naphthalene dicarboxaldehyde (NDA) derivatization, respectively. Peroxides and quinones had the largest effects on antioxidant genes expression at 6 or 24 h after exposure and only quinones caused significant GSH depletion. Overall the transfected cell lines were more resistant to chemical toxicity and showed marked decrease in OS biomarkers. The differences in viability effects were largest for peroxides and quinones and absent for Dinoseb. Finally, the temporal expression pattern of *Nqo1* gene differed from other antioxidant genes and was largely affected by quinone exposure. Given the biological data and known multifaceted biological function of quinones, the contributions of redox cycling and arylation to cytotoxicity and GSH depletion were evaluated computationally. Model results agreed with biological observations and indicated that t-butyl hydroperoxide produced ROS more readily than hydroquinone, while hydroquinone is more reactive towards GSH and other intracellular nucleophiles. The results highlight the importance of modes of action and molecular initiating events in chemical toxicity and the vital role of GSH in peroxide and quinone metabolism in vitro. Furthermore, the work emphasizes the opportunities presented by computational chemistry in elucidating modes of action and assessing chemical toxicity.

**WP122 Acute and Chronic Effects of Sodium Chloride on 3 Fish Cell Lines and Their Suitability as in vitro Alternatives**

*T.R. Bouchard, Lakehead University / Biology; P. Lee, Lakehead University*

Millions of animals are used annually for regulatory testing worldwide. Recent changes in government regulations have led to an increased need to find suitable alternatives for animals in testing. One potential alternative is the use of fish cell lines for in vitro toxicity tests. Fish cell lines have been studied as an in vitro alternative as they are derived from the organisms being replaced. In this study we evaluated the suitability of three fish cell lines as in vitro alternatives for acute and chronic toxicity testing. The study utilized the RTL-W1, RTGill-W1, and FHML cell lines and evaluated their responsiveness to acute and chronic exposures to NaCl using a modified crystal violet assay. The cell lines were plated in 96-well plates and then exposed to a solution containing L-15media spiked with NaCl. Exposure periods varied from 24hrs to 48hrs for acute and chronic tests respectively. Exposed cells were stained with crystal violet and their absorbance was measured at 570nm. $EC_{50}$ and $IC_{25}$ values were calculated using the absorbance values and compared to in vivo literature values acquired from the ECOTOX online database. The RTGill-W1 $EC_{50}$ value of 20.02g/L was found to not be significantly different from the Rainbow trout literature value of 8.92 g/L, while the RTL-W1 $EC_{50}$ value of 1.026 g/L was found to be significantly different from the literature value. The FHML cell line $EC_{50}$ value of 16.27 g/L was found to not be significantly different from the literature value of 7.25 g/L. Due to limited chronic literature data involving rainbow trout, $IC_{25}$ values from all three cell lines were compared to literature values for fathead minnows. The RTGill-W1 cell line had an $IC_{25}$ of 5.77 g/L, the RTL-W1 had an $IC_{25}$ of 1.19g/L, and the FHML cell line had an $IC_{25}$ value of 1.51 g/L and none of these values were found to be significantly different from the literature value of 1.72 g/L. These results demonstrate the potential for cell lines to be used for acute and chronic in *vitro* testing. Further studies will work to confirm the results of these tests, as well as to determine if this method can be applied to other toxicants and real world samples.

**WP123 F2-Isoprostanes in fish mucus: A new, non-invasive analysis of oxidative stress biomarkers**

*P. Bulloch, S. Schur, University of Manitoba / Department of Chemistry; D. Muthumuni, University of Manitoba; Z. Xia, W. Johnson, University of Manitoba / Chemistry; V. Palace, IISD Experimental Lakes Area; R.J. Letcher, Environment and Climate Change Canada / Ecotoxicology and Wildlife Health Division; G. Tomy, University of Manitoba / Department of Chemistry*

Prostaglandin-$F_2$-like derivatives, namely the F2 isoprostanes (F2-isoPs), have emerged as a reliable biomarker class for oxidative stress in mammals and fish. F2-isoPs are the free-radical catalyzed products of non-enzymatic lipid peroxidation of arachidonic acid, a fatty acid found in brain tissue and cell membranes. Fish mucus has been investigated in several studies as a potential biological matrix for the analysis of oxidative stress, as it is minimally invasive. It is composed mainly of glycoproteins, but notably contains immunoglobulins, pheromones, lysozyme and proteolytic enzymes. Mucus is known to have important biological functions for fish, ranging from communication and reproduction to osmotic regulation. To date, no method for the isolation and quantification of F2-isoPs in fish mucus has been reported. The aims of this study was to develop an efficient method for the extraction of F2-isoPs from fish skin mucus and to optimize the resolution and quantification of F2-isoPs by high-performance liquid chromatography tandem mass spectrometry. The method was based on an extraction of mucus with methanol under acid conditions. The extract was then centrifuged, filtered, and concentrated. Separations were performed on C18 (2.1mm x 50mm, 3.5µm particle size) column using methanol (0.1% formic acid) and water as the mobile phase. Negative electrospray ionization and specific multiple reaction monitoring ion transitions were used to detect F2-isoPs in mucus. Mass labelled internal standards were used to monitor recovery of native compounds during sample work-up and also to quantify native F2-isoPs. Native isomers of the Class III and VI F2-isoPs were measurable in Northern Pike (*Esox lucius*), lake trout (*Salvelinus namaycush*), and small mouth bass (*Micropterus dolomieui*). This work demonstrates that mucus has the potential to be used as a non-invasive, non-lethal matrix for F2-isoPs analysis in fish.

**WP124 Development of methods for the assessment of vision and neurological function in larval fathead minnows**

*J. Krzykwa, K. Roush, M.K. Sellin Jeffries, Texas Christian University / Department of Biology*

Recent efforts have begun to expand the zebrafish fish embryo toxicity (FET) test to other test species, including the fathead minnow. While studies have suggested that the zebrafish FET test method is transferable to the fathead minnow, there is interest in modifying the fathead minnow FET test to allow for estimation of sublethal adverse effects so that it could be used as a potential replacement for not only acute tests, but also chronic tests. To assess sublethal adverse effects, appropriate sublethal FET test endpoints must first be identified, then their predicative ability must be assessed. Previous studies have identified embryonic eye size as a potential FET test endpoint, and though there is limited evidence suggesting that these alterations are indicative of altered neurological development, studies validating the link between eye size and organism fitness are needed. The overarching goal of this project is to investigate whether reduced embryonic eye size at the conclusion of the FET test is predicative of altered vision or neurological function in larval fathead minnows. However, assays must first be developed to assess of vision and neurological function in larval fathead minnows. Therefore, the objective of the present study was to develop methods to assess vision/neurological function in larval fathead minnows. One method utilized to evaluate vision in fish is the assessment of optomotor response (OMR), an instinctual response in which a fish follows a moving reference point. Factors such as at what age fish reliably exhibited OMR, the necessary acclimation time, and the relationship between larval size and OMR were evaluated. The results of this study indicate that larval fathead minnows exhibit detectable OMR starting at 9 days post fertilization (dpf) and 4 min of acclimation to the chamber is needed. Interestingly, there is a significant relationship between length and OMR response, suggesting that larval size should be taken into account in future studies utilizing OMR as a metric. These results will be utilized in future studies investigating whether reductions in embryonic eye size are predictive of sublethal adverse effects and can also be utilized by other researchers interested in assessing vision/neurological function in larval fathead minnows.

## Sustainability and Ecosystem Services: From Science to Societal Choices

**WP125 Determinants of participating in the Deepwater Horizon oil spill cleanup**

*D. Sharpe, J.A. Kaufman, Emory University / Epidemiology; Z.E. Goldman, Emory University / Environmental Health; A. Wolkin, Centers for Disease Control and Prevention / Office of Public Health Preparedness and Response; M.O. Gribble, Emory University / Environmental Health*

The *Deepwater Horizon* oil rig spilled 4.9 million barrels of oil in the Gulf of Mexico on April 20, 2010. An environmental disaster of such magnitude has detrimental effects on people living in affected areas; engagement of community members in recovery efforts is important for mitigating some adverse effects of oil spills. Few studies have explored factors that determine participation in oil spill cleanups, motivating this study. Publicly accessible data from the Gulf States Population Survey (GSPS) were analyzed to study the determinants of participation in the Gulf oil spill cleanup. Conducted by the Centers for Disease Control and Prevention from December 2010 to December 2011, the GSPS was a telephone survey of 38,361 adults in counties and parishes in Alabama, Florida, Louisiana, and Mississippi impacted by the oil spill. We used survey estimation to account for the complex survey study design and used multiple imputation by chained equations to handle missing data. We estimated the probability of participating in the cleanup among demographic subgroups and used univariate logistic regression models to test whether demographic factors were associated with participation. Approximately 4.6% (95% confidence interval [CI]: 3.7-5.6) of residents in these communities participated in the oil spill cleanup. Participants in cleanup efforts were mostly aged 25-34 years (26.8%; 95% CI: 17.7-35.8), men (56.1%; 95% CI: 45.7-66.5), non-Hispanic white (68.1%; 95% CI: 57.4-78.9), and employed at the time of the survey (64.2%; 95% CI: 53.3-75.1). Many cleanup participants (65.0%; 95% CI: 54.6-75.4) reported very good or excellent overall health at the time of the survey. Different frequencies of specific cleanup tasks were reported: over 70% (95% CI: 61.8-80.5) of cleanup participants assisted with beach or marsh cleanup, while only 3.7% (95% CI: 0.51-6.9) participated in well-head cleanup or controlled burning. Logistic regression analyses indicated that living in an affected coastal county was significantly associated with higher odds of participation in a cleanup (unadjusted odds ratio [OR]: 1.70; 95% CI: 1.29-2.25), as was having excellent or very good physical health (OR: 2.08; 95% CI: 1.14-3.77). Older persons were less likely to participate in the cleanup (OR for 65+ age group vs. 18-24 age group: 0.14; 95% CI: 0.05-0.35). Understanding the demographics of cleanup participants may help future oil spill responses determine how best to recruit community members in this region.

**WP126 Assessing the potential opportunities and tradeoffs of algal growth from wastewater**

*T. Mathews, S. Mandal, Oak Ridge National Laboratory / Environmental Sciences Division; R. Efroymson, Oak Ridge National Laboratory*

Algae holds much promise as a potential feedstock for biofuels, but large-scale algal biomass production has not yet demonstrated the performance required for the economical production of biofuels. To date, the biofuel industry has focused on algal monocultures- single species of algae that have high growth rates and lipid accumulation potentials when cultured under controlled laboratory conditions. However, scaling up monocultural production has remained a significant challenge because monocultures are extremely susceptible to pests and disease. Further, nutrient and water supplies will become limiting as we scale up production unless new approaches are developed to mitigate these resource constraints. The use of wastewater resources that are rich in nitrogen and phosphorus to supplement a portion, or completely replace, traditional fertilizer and water requirements may help significantly reduce algal production costs and conserve freshwater resources. Here we examine the performance of monoculture and polyculture algal crops in two case studies: municipal wastewater, and the waste from biofuel production. We examine the economic and environmental benefits, tradeoffs, and scalability of each of these case studies. Our results suggest that cultivating and managing algal polycultures in wastewater may be a more sustainable and cost-effective solution for the biofuel industry than the current practice of monoculture production.

## Recent Advances in Training, Online Support and Responsible Management Practices for LCA Databases

**WP127 Bringing it all together: Green Design and Assessment (GDA) Workbook**

*A. Nestler, A. Baker, L. Heine, Northwest Green Chemistry*

In order to design products for the circular economy, designers must complete an assessment of key product sustainability attributes at the earliest stage possible. This is essential to avoiding the sunk cost effect and providing ample time to redirect efforts if terminal problems are discovered. Designers understandably struggle to weigh tradeoffs. It's challenging to compare GHG emissions to toxicity, ethical working conditions to cost, or hazardous materials to performance. Guidance for making such decisions is the groundwork needed to usher in a functional circular economy. Northwest Green Chemistry (NGC) created the GDA Workbook, which is free and publicly available online, to help entrepreneurial product designers overcome this barrier. It is rooted in three overarching green chemistry and engineering principles: preserve natural capital, eliminate toxics in products & processes, and design holistically using life-cycle thinking. It informs early-stage assessment and empowers designers to continually improve products. This presentation will include an overview of the workbook with case studies. NGC collaborated with diverse stakeholders to better understand what businesses need to effectively evaluate and optimize product sustainability. An overarching theme was the desire for simple checklist-style guidance to evaluate whole products, not just individual chemicals. Businesses need a way to synthesize chemical hazard assessment, exposure assessment, and life cycle assessment (LCA) into a single, multifaceted evaluation. The Workbook enables this by benchmarking each life cycle stage against sustainable design principles using currently available tools. The GDA Workbook is designed to be accessible for those with varying expertise in sustainability, offering screening and advanced modules, and helping bridge the communications gap between sustainability scientists, designers, engineers, managers, and the public. It can help resource-strapped designers pinpoint problem areas and determine in which technical assessments, like formal LCA, to invest. This proactive approach can be applied by any product or process designer to optimize the sustainability of their product while avoiding unexpected trade-offs or costs. This approach creates an entry point into the complex world of sustainability and the circular economy. The interactive tool offers unique support by aligning tools with principles in support of a resilient circular economy.

**WP128 Data Modalities and Institutional Roles in Life Cycle Inventory Data**

*B. Kuczenski, University of California, Santa Barbara; P. Arbuckle, E. Kahn, USDA*

The current paradigm for life cycle inventory data management, typified by large, centrally maintained databases that are monolithic and infrequently updated, has struggled to provide the granularity and representativeness required for many studies. At the same time, there is no easy way for authors of different LCA studies to collaborate or share their work with one another. While the topic of data interchange and interoperability receives a lot of attention, comparatively little work has focused on workflows and best practices for making data and models available for use. We address this gap by considering the different kinds of information that are relevant to preparing and sharing LCA studies, and the roles of different agents in supporting the task of building a life cycle model. LCI data are often organized in terms of unit processes and flows, because these formative concepts are ubiquitous in the standards and the literature. However, we find they are not well suited for organizing practitioner knowledge. We find that life cycle data contains three distinct modalities, each of which requires a different approach for organizing and sharing. By volume, the vast majority of information in an LCI database is qualitative, also known as metadata, which includes scope, system boundary, representativeness and methodological characteristics. The quantitative mode, by contrast, includes limited, strictly numeric data: the amount of a given flow that is associated with the activity of a given process. We identify a third, semi-quantitative mode that is often neglected in LCI data discussions, namely the adjacency of processes, or which processes are partners in an exchange. For all three modalities, the exchange, and not the unit process, is the most "atomic" unit for storing and sharing knowledge. Beyond the exchange, the product system (and not the unit process) is more representative of how knowledge about systems is gathered and organized. From this perspective, unit processes are aggregations of product systems -- derived rather than primary datasets. We will discuss the differing roles and interests of practitioners, study commissioners, academic researchers, data providers, public agencies, and non-governmental organizations in creating and curating these different kinds of information.

**WP129 LCA and AA: An Integrated Screening Approach**

*H. Plugge, Verisk 3E; E. Griffing, Environmental Clarity; M. Overcash, Wichita State University / Industrial, Systems, and Manufacturing Engineering Department*

In the last few years there has been a trend from detailed assessments at the end of a product design cycle, to screening of risks in an earlier phase, the so-called Test Early, Fail Early paradigm. Various risk screening methodologies have been initiated at the hazard and risk level. A screening approach to LCA is more of a novelty, especially when integrated with health and environmental hazard and risk screening. Alternatives Assessment (AA) especially cries out for a screening approach. The original NAS AA report about 4 years ago described an integrated approach for performing AA's which included LCA in the decision scheme. Previous presentations by the authors have suggested incorporation of an integrated screening approach early in the AA scheme, in order to allow preliminary screening of alternatives, without engaging in multimillion dollar full-blown assessments. A rapid preliminary decision can be reached albeit commonly on an incomplete dataset. The initial tenet of AA is deceivingly simple: maintain functionality. Substitution will never succeed if the alternative does not perform at least equal to the original chemical. Screening health and environmental effects can be calculated using 3E's Green Score methodology. Environmental Clarity 's Life Cycle Inventory (LCI) methodology provides a rapid screening LCA estimate based on process engineering based LCI data. NRE (Natural Resource Energy) and GWP (Global Warming Potential) metrics are used on a cradle to gate (CTG) scope. Results are then presented in a decision matrix allowing (de)selection of alternatives. A case study will be presented based on alternatives and analogues to C3 and C4 alcohols. Contrary to common assumptions C4 alcohols are not at all similar with regard to their physicochemical properties, slightly similar with regard to health effects and more similar with regard to LCA impacts and environmental effects. Screening data for the series ethanol through 1-pentanol will be presented and decision pairs selected and screening estimates provided for all. None of the butanols are equivalent/provide a good substitute to tert-butanol, although isopropanol does, based on functionality.

**WP130 LCA Data Management – Current Status and Future Directions**

*B.W. Vigon, Breveja Environmental Consulting LLC*

Since the publication of the Global Guidance Principles for LCA Databases in 2011, a great deal has been done to develop and implement in a practical way, the recommendations of that workshop. This presentation will summarize those efforts and provide an integrative perspective on how the various activities complement one another. In particular the projects of the Life Cycle Initiative, both the previous phases and the current one, the UN Environment REAL Project, and the GLAD Network, will be covered. The objective of this look-back will be to both highlight earlier identified needs in the data arena and spotlight gaps that still should be addressed going forward. Efforts to date have included development and roadtesting of data review procedures and criteria. These criteria have been or are being incorporated into the meta-data fields available when users log into the GLAD portal. In a parallel vein a basis for assessing database conformance to recommended management practices first listed in the Global Guidance Principles, have been elaborated and tested on multiple databases in developed and developing countries. Both of these advancements have been supported by the Life Cycle Initiative and the UN Environment LCA Databases Helpdesk.

**WP131 LCA in organizations: It can tackle climate change?**

*W.H. Motta, IBICT / Information Science Post-Graduation Program*

Climate change is increasingly recognised as a major challenge, among other problems arising from the experienced ecological crisis. It is widely accepted that the greenhouse gas emissions caused by humans are having a negative impact on the environment, causing serious implications for the ecosystem and consequently for human life. Contributed in a sweeping way in the alteration of the carbon cycle and other cycles of matter and energy in the terrestrial system, leading to the term "Anthropocene" for the present time. Particularly after the commitment that 195 nations made through the Paris agreement (COP 21), the issue became even more widespread and has positioned itself at the top of the political environmental agenda and as one of the main environmental issues addressed by society in general. Due to this reality, the growing awareness of the need for environmental sustainability in personal life and at work has increasingly brought "sustainable" practices to the agenda of organizations. Environmental constraints are increasingly being imposed on organizations and require new levels of operational compliance, thus promoting the need to apply and use new methodologies and tools. Among these methodologies can be pointed out Life Cycle Assessment – LCA, that has been increasingly accepted as a way to assess the environmental impacts associated with all stages of a product's life. It encompasses the entire production chain: the extraction of natural resources, transport, production process, consumption and disposal of products (waste). Taking into account an LCA study being performed considering only the impact category of greenhouse gas emissions, it can for example consider from direct use of fuels to indirect impacts such as employee travel or emissions from other organisations up and down the supply chain. In this context, could LCA in organizations contribute to tackle climate change? In what way has LCA been used by organizations? The present study aims to shed light to this discussion through a literature review analysing the use of LCA by organizations and its potential facing climate change challenges. The evolution of the use of LCA by organizations promises fruitful results in this regard.

**WP132 Life cycle assessment of aquaponics and agriculture informed by literature review**

*F. Wu, University of Wisconsin, Madison / Chemical, Biological and Environmental Engineering; A. Hicks, S. Jacobsen, University of Wisconsin, Madison / Department of Civil and Environmental Engineering*

As the global population continues to grow and resources continue to dwindle, there is an abundant need for prolific and sustainable food systems. Recently, the interest in aquaponics has grown. The number of commercial facilities in the US has more than doubled from 71 to 145 from 2013 to 2015. Aquaponics, a closed loop production system of food and produce products, is one emerging method of food production which may have much lower environmental impacts than conventional food systems, while providing an environmentally sustainable protein source. Fish excrete ammonia which is broken down by bacteria into nitrite. The plants utilize the nitrite and act as filters by removing the nitrite from the recirculating water. By employing the symbiotic relationship between the fish and the plants, aquaponics can reduce the amount of inputs needed and lessen the impact on the environment compared to traditional farming. Life cycle assessment (LCA) is a widely accepted and useful tool that assesses the environmental effects of products and services. Thus, LCA is a holistic approach that quantifies the direct and indirect environmental impacts and can help identify the most sustainable and least sustainable aspects of a product or service. This poster is aiming to introduce and compare the current LCAs that have been performed on aquaponic systems at relative environmental categories to date. Based on current information, most systems use tilapia, a warm water fish, and a variety of vegetable are grown the most popular being herbs, lefty greens, and tomatoes. In addition, although aquaponics offers a promising sustainable food system solution, the profitability of the system can vary depending on location, laws, species of vegetables and fish grown, and markets the products are sold in. This poster review also looks at the techno-economic assessments that have been performed on aquaponic systems.

**WP133 Environmental and economic performance evaluation of decentralized wastewater treatment plants in India using life cycle approach**

*S. Kamble, A. Singh, National Institute of Industrial Engineering / Environmental Engineering and Management; A. Kazmi, Indian Institute of Technology, Roorkee / Department of Civil Engineering; L. Philip, Indian Institute of Technology, Madras / Department of Civil Engineering; M. Starkl, University of Natural Resources and Life Sciences, Vienna / Competence Centre for Decision Aid in Environmental Management*

Life cycle assessment (LCA) was used to evaluate the environmental impacts associated with wastewater treatment plants (WWTPs). Six most commonly used wastewater treatment technologies in India, namely; Sequencing batch reactor (SBR), Membrane bioreactor (MBR), Moving bed biofilm reactor (MBBR), Soil biotechnology (SBT), Aerated lagoons (AL) and Activated sludge process (ASP) have been evaluated. CML Baseline 2000 method was used for assessing life cycle impacts considering eleven potential impact categories. The scope of the study considered operation and maintenance phase, sludge treatment and landfilling, and the transportation of sludge to landfill. Moreover, an economic evaluation was also addressed using life cycle cost (LCC) approach employing present worth method. It is evident from LCA that emissions associated with electricity production for operating the WWTPs, emissions into water bodies from the treated effluent and hazardous heavy metals emissions into effluent and waste sludge have been identified as the main contributors to the overall environmental impact. Marine aquatic ecotoxicity potential was found to be the most significant impact category in the WWTPs under consideration. Among the wastewater treatment technologies, SBT obtained the lowest environmental impact in all the evaluated impact categories, except for eutrophication potential. While, the AL system presented the worst results due to the high electricity and chemicals consumption. On the other hand, the present worth of SBT was estimated to be Rs. 40 million/MLD which is highest as compared to other technologies. This high cost is due to land requirement and high density polyethylene liner cost. MBR is second highest (Rs. 24.7 million/MLD), which is mainly contributed by civil, electro-mechanical and membrane cost. The results of LCA and LCC provide specific insights about the factors which play a major role during the life cycle of wastewater treatment technology and its associated impacts. A comprehensive LCA and LCC have been documented in the present study which can help decision makers to take well informed decisions simultaneously addressing sustainability.

## Assessing Contaminant Effects on Early Life Stages of Marine Organisms

**WP134 Physiological consequences of environmental contamination in an elasmobranch with matrotrophic histotrophy, the Round Stingray**

*K. Lyons, California State Univ, Long Beach / Biological Sciences; K.E. Wynne-Edwards, University of Calgary / Faculty of Veterinary Medicine*

Despite widespread evidence of negative reproductive effects in most other vertebrate taxa from organic contaminant exposure, similar studies in elasmobranchs are limited. We examined a range of physiological biomarkers in two populations of Round Stingray (*Urobatis halleri*) that differed primarily in PCB exposure in southern California (USA). Females, and their embryos, were sampled each month of pregnancy at both sites, while adult males were matched with a 40-day subset of females to investigate the effect of sex and its interaction with PCB exposure and development. Exposure was hypothesized to have negative outcomes for PCB-exposed stingrays compared to the reference population. We found a variety of impacts, ranging from reproduction to osmoregulation. Female fecundity was not affected by PCB exposure; however, exposure exacerbated maternal tissue mass, and quality, loss during pregnancy. Embryos from contaminant exposed sites appeared to not use maternal resources as efficiently as their reference counterparts. Sex-related differences in embryo mass differed between sites, with males being relatively heavier than females in the reference site but not the expose site, suggesting contaminant effects on males begin *in utero*. These contaminant sex-related effects extended into adulthood, as relative liver mass and energy content were lower in comparably-sized adult males than females from the exposed site, whereas fewer differences were found between adults at the reference site. Effects found both *in utero* and in adulthood suggest that contaminants have a significant, and potentially life-long, impact on Round Stingray homeostasis. This has implications for other species with greater contaminant burdens. Contaminant exposure, and its interactive effects with sex and age, should be included as part of effective elasmobranch management.

**WP135 Accumulation, elimination and neuro-oxidative damage under lanthanum exposure in glass eels (*Anguilla anguilla*)**

*C. Figueiredo, T.F. Grilo, MARE Marine and Environmental Sciences Centre; C. Lopes, P. Brito, Portuguese Institute of Sea and Atmosphere IPMA; M. Diniz, UCIBIO / REQUIMTE; M. Caetano, Portuguese Institute of Sea and Atmosphere IPMA; R. Rosa, MARE Marine and Environmental Sciences Centre; J. Raimundo, IPMA / DIVOA*

Rare earth elements (REEs) comprise elements from lanthanum to lutetium that together with yttrium and scandium are emergent contaminants of critical importance for numerous groundbreaking environmental technologies. Transfer to aquatic ecosystems is expected to increase, however, little information is known about their potential impacts in marine biota. Considering the endangered conservation status of the European eel (*Anguilla anguilla*) and the vulnerability of early fish life stages to contaminants, we exposed glass eels, through water, to an environmentally relevant concentration (120 ng.L-1) of lanthanum (La) for 7 days (plus 7 days of depuration). The aim was to study the accumulation and elimination of La in eel's body and subsequent quantification of acetylcholinesterase (AchE), lipid peroxidation and antioxidant enzymatic machinery. Accumulation peaked after 72h-exposure to La, decreasing afterwards, even in continuous exposure. Accumulation was higher in the viscera, followed by the skinless body and ultimately in the head, possibly as a protective mechanism to cope La neurotoxicity. A significant increase in AChE activity was observed in La-exposed glass eels, suggesting that $La^{3+}$ may inhibit the binding of acetylcholine. A depression in lipid peroxidation was registered under La exposure, possibly indicating that $La^{3+}$ may play physiological activities and functions as a free radical scavenger. Catalase activity was significantly inhibited in La-exposed glass eels after 72h, indicating that the availability of La may induce a physiological impairment. The quantification of Glutathione S-Transferase activity revealed no differences between control and La-exposed organisms. Further investigation is needed towards understanding the biological effects of REEs.

**WP136 Assessment of cardiac toxicities in embryos of marine medaka exposed to oxygenated PAHs spiked into artificial sediment**

*S. Uno, Kagoshima University / Faculty of Fisheries; S. Nakamura, Kagoshima University; E. Kokushi, Kagoshima University / Education and Research Center for Marine Resources and Environment; M. Kawano, Kagoshima University / Faculty of Fisheries; K. Anraku, Kagoshima University*

Many kinds of chemicals have been residues in sediments of coastal area, especially closed to the big cities and industrial zone. Some of them are persistent such as polycyclic aromatic hydrocarbons (PAHs), and possibly affect especially in the benthic animals. Oxygenated PAHs (oxyPAHs) have one or more oxygen molecules connected by a double bond to the benzene rings in PAHs. They are discharged directly into the environment with the exhaust gas from diesel engine automobiles and flue gases from various combustion process. After transferring into the water columns, oxyPAHs absorb on the micro-particles and can settle on sediments in the coastal area. Previously, we reported the cardiac malformation caused in freshwater medaka embryos exposed to oxyPAHs such as 7,12-benz(a) anthracenequinone (BAQ) and 9,10-phenanethrenequinone (PHQ). From these results, oxyPAHs possibly cause the cardiac toxicities to fish embryos. If we can find the diagnostics of cardiac toxicities in the early embryos of fish, we consider that the potencies of cardiac toxicities even in larvae can be predicted. In the present study, we tried to assessment the cardiac toxicities in the embryos of marine medaka, Java medaka (*Oryzias javanicus*), exposed to oxygenated or parent PAHs spiked into the artificial sediments. The examined compounds were BAQ, PHQ, 1,4-naphthoquinone (NAQ) as oxyPAHs, and pyrene as parent PAH. Those were spiked into the artificial sediments made with reference to TG218 in OECD test guideline. Ten embryos were embedded in half of them in sediment, which was laid at a glass petri dish, and were developed on the sediment for 12 days post-fertilization (dpf). In the period, the rearing water was not added to the dishes, and sediment contained slight amount of pore water (artificial sea water). The embryos at 5 or 12-dpf were shot video under a microscope. Then, only the cardiac part in the video were left, and others were cropped. The temporal variations of areas on the heart were crimped. We regarded the crimp as a similar to electrocardiogram, and determined arrhythmic heartbeat after measuring heartbeat. In this method, we could clearly observe the cardiac abnormalities for heartbeat and arrhythmic heartbeat in embryos at 12-dpf compared with them at 5-dpf. Especially, NAQ tended to be increased the frequencies of arrhythmic heartbeat in embryos even under lower concentrations (0.33 mg/kg), NAQ can sensitively cause cardiac toxicities.

**WP137 Potential Population-level Impacts of Oil Spills on Puget Sound Pacific Herring Stocks**

*J.A. Spromberg, Northwest Fisheries Science Center / NMFS; S.E. Allan, NOAA / Office of Response and Restoration; N. Scholz, NOAA Fisheries / Northwest Fisheries Science Center*

Localized oil spills that contaminate nearshore spawning areas pose a threat to developing Pacific herring embryos. Fish embryos are particularly susceptible to the developmental toxicity of oil-derived PAHs, which can be acutely lethal or, at lower exposure doses, lead to permanent changes in heart structure, craniofacial morphology, and metabolic processes that cause delayed mortality, or more subtle delayed impacts that may be associated with premature subadult mortality. A variety of localized oil spill scenarios simulating direct and delayed mortality to young of the year were used to examine the potential response of Puget Sound stocks. The healthy stocks remaining in Puget Sound could withstand short term impacts, but the growing number of depressed and unhealthy stocks are vulnerable to an increased risk of localized extinction. Model output predicted that for short term, low level impacts the stock abundance did not exceed the natural variability observed in the population demographic data. This indicates a limited ability to observe in the field any predictions made by the model. High mortality in a single year or impacts across multiple year classes may cause stock abundance changes that exceed natural variability. Despite this, the model does indicate the magnitude of impact on the intrinsic growth rate that could reduce productivity of affected stocks. Additional toxic endpoints and effects thresholds are currently being investigated, including sublethal impacts on cardiac function, immune function, and lipid metabolism that may all lead to delayed mortality. Characterizing these adverse outcome pathways may alter predicted impacts of oil spills on herring stocks by informing, systematic post-spill field assessments measuring exposure concentrations and assessing the proportions of herring embryos, larvae, or juveniles showing specific phenotypes (e.g., cardiac edema) or gene regulation patterns indicative of changes in individual fitness via swimming ability, immune function, or lipid metabolism. These data may be useful for any injury assessment for Pacific herring.

**WP138 Crude oil cardiotoxicity and growth throughout development in Pacific herring (*Clupea pallasi*)**

*A.D. Cypher, NOAA Fisheries / Env Fisheries Division; J. Incardona, T. Linbo, NOAA Fisheries / Northwest Fisheries Science Center*

Several years after the 1989 Exxon Valdez oil spill, the Pacific herring (*Clupea* pallasi) population of the Prince William Sound crashed and never recovered. Despite finding that larval herring are extremely sensitive to low concentrations of polycyclic aromatic hydrocarbons (PAHs), the connection between oil spill events and delayed population-level effects has yet to be established. The developing heart is the primary target of crude oil toxicity and therefore the most likely starting point for the cascade of events leading to reduced recruitment at the population level. By tracking cardiac morphology and growth between larval hatch and metamorphosis to juveniles, this study was intended to evaluate relationships between embryonic cardiotoxicity and delayed population impacts of oil spill events. Herring embryos were exposed to six concentrations of oil ranging from 0 to 5.1 ppb ∑PAHs from 24 hours post fertilization to 10 days and subsequently reared in clean sea water. Oil concentrations were maintained by a dispersion generator which injected microdroplets of Alaskan North Slope crude oil into the exposure system. Larval length, cardiac edema, and ventricle and atrium area and shape were assessed weekly by video microscopy through metamorphosis, approximately 80 days post hatch. Preliminary results indicated that the cardiac morphology of larval herring was more sensitive to oil than the analytical methods for detecting waterborne oil. At near-detection limit concentrations, we observed cardiac edema, reduced ventricular area, enlarged atrium, and altered ventricular shape. This change in shape can reduce cardiac output and consequently aerobic capacity, which could impact survival as fish reach adulthood. This work is part of a larger collaboration intended to evaluate the effects of larval cardiovascular morphology, lipid composition, and gene expression on juvenile bioenergetics and susceptibility to infectious and parasitic diseases.

**WP139 Development of a Novel Acute Toxicity Method for a Marine Copepod: Sensitivity to Copper, Phenanthrene and Ammonia**

*A.J. Kennedy, US Army Engineer Research and Development Center / Environmental Laboratory; T. Biber, Army ERDC; L. Rabalais, US Army ERDC; G. Lotufo, Army Engineer Research and Development Center; D. Farrar, USACE / ERDC / Enviromental Laboratory; A. Bednar, USACE / ERDC*

There are limited acute (48 hour) toxicity test methods for marine species that are considered zooplankton for their entire life cycle. Examples of current standardized marine zooplankton methods include mussel, bivalve and echinoderm development tests that focus on planktonic life forms that consist of only a very short duration of the organism's life cycle or chronic life cycle copepod toxicity tests that involve epibenthic species. A currently available ISO method lists an acute, 24 hour test using a marine planktonic species of copepod that is not indigenous to North America. The objectives of the present study were to (1) develop a novel 48 hour acute toxicity test method using a marine copepod species indigenous to North America that is planktonic for its entire life cycle; (2) make modifications to the test method applicable to sediment elutriate toxicity testing; and (3) determine the sensitivity of this copepod to copper, phenanthrene and ammonia relative to other commonly used marine toxicity test species. The calanoid copepod *Pseudodiaptomus pelagicus* was selected as the test species and was exposed to each of the three model toxicants in five separate 48 hour toxicity tests. The average lethal median concentration (LC50) values for copper, phenanthrene and un-ionized ammonia were 33 ± 13 µg/L, 161 ± 51 µg/L and 1.08 ± 0.30 mg/L. Toxicological endpoints were generated by summarizing data based upon dissolved chemical stability in the water column, with arithmetic means used for copper and un-ionized ammonia and geometric means for the less stable dissolved concentrations of phenanthrene. These LC50 values placed *P. pelagicus* on the more sensitive range of copper and phenanthrene species sensitivity distributions. The copepod was less sensitive to un-ionized ammonia than mussel and urchin development toxicity tests. The results suggest *P. pelagicus* is relatively sensitive to typical contaminants of concern released to the water from sediment elutriates but less sensitive to naturally occurring ammonia levels released from sediments. No effect levels calculated as USEPA benchmark dose low values were determined to provide a frame of reference for when effects due to these chemicals are not expected to occur. Additional research developing this method includes an inter-laboratory comparison.

## Tackling Urban Background: Approaches, Case Studies and Policy Implications

### WP140 Background and Bioaccessible Concentrations of PAHs in Florida Urban Soils

*P. Gao, E. Da Silva, University of Florida / Soil and Water Sciences; T. Townsend, University of Florida / Department of Environmental Engineering Sciences; L. Ma, SW Forestry University / Research Center for Soil Contamination and Environment Remediation*

Soil cleanup standards for contaminated soils can be based on either soil background concentrations or risk-based values. Mounting evidence suggests that understanding contaminant bioavailability in soils is necessary for accurate assessment of contaminant exposure to humans via oral ingestion pathway. Polycyclic aromatic hydrocarbons (PAHs) are a group of contaminants come from biogenic, petrogenic and pyrogenic sources in the environment. The objective of this study was to determine the total and bioaccessible concentrations and distributions of PAHs in Orlando and Tampa urban soils. The results showed the soils were dominated by high molecular weight PAHs in both cities. Benzo(a)pyrene equivalent (BaP-EQ) concentrations in 60-63% samples were higher than residential Florida soil cleanup target level (FSCTL) and 20-25% samples were higher than industrial/commercial FSCTL in Orlando and Tampa. Orlando soils had relatively higher bioaccessible PAHs and BaP-EQ concentrations than Tampa soils, and both cities had similar PAHs bioaccessibility which ranged from 0 to 93%. The bioaccessible BaP-EQ concentrations in both cities were under industrial/commercial FSCTL. High molecular weight PAHs had relative lower bioaccessibility than low molecular weight PAHs due to the hydrophobic characters. Based on molecular diagnostic ratios and PMF model, major sources of both total and bioaccessible PAHs in both cities were similar, mainly coming from pyrogenic, traffic emissions, and biomass and coal combustion. Based on ArcGIS maps, total PAHs concentrations in central business district and areas near high traffic roads were significantly higher than the other areas in both cities.

### WP141 Characterizing Urban Background Levels for Contaminated Site Cleanup

*F. Barnett, USEPA Region 4 / Superfund; T. Frederick, USEPA Region 4; G. Adams, B. Alfano, S. Chan, USEPA / Region Superfund Division; B. Schumacher, USEPA / ORD / NERL; R. Ford, USEPA / Office of Research and Development*

Identifying the source of soil contaminants is vital to decision-making during an environmental cleanup. Soil in long-established cities has accumulated decades of low level concentrations of metals and other chemicals like polynuclear aromatic hydrocarbons (PAHs) caused by urban activity. The combination of natural and anthropogenic background levels of chemicals is known as urban background contamination. These metals and chemicals can intermingle with higher concentrations of chemicals from spills and industrial waste creating challenges in understanding how industrial site contamination is contributing to overall soil concentration levels and in establishing protective and achievable clean-up goals. EPA and state officials collaborated on a multi-city sampling study created to assist hazardous waste site managers differentiate between site-related contamination and contamination from nearby non-point sources (urban background contaminants). This study goal was to design a data acquisition process to characterize levels of contaminants in a city that derive from natural and urban infrastructure sources not related to chemical spills and industrial waste and to develop a project database in which soil concentration data and sampling location metadata are compiled for all sampled cities. EPA worked in cooperation with representatives from the Southeast Region States (Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee) to develop a unified plan for the selection of sampling locations and implementation of a consistent sampling approach for application across all States. The finalized plan was applied at eight cities to evaluate implementation consistency and provide training to participating State personnel then used in a case study to aid in establishing background concentrations for a Superfund site.

### WP142 The Role of Urban Background in Site Investigations: A Spectrum of Ramifications

*M.W. Kierski, Exponent / Ecological and Biological Services Practice; K. O'Reilly, Exponent / Environmental and Earth Science; M. Edwards, Exponent / Environmental and Human Health Consulting*

Many contaminated sites being investigated under federal and state regulatory programs are located in urban centers with their own contamination problems from decades of historical mixed industrial and commercial land use. This presents unique challenges for site investigations in urban centers, as opposed to less urban areas where the levels of contaminants in the ambient environment can be clearly distinguished from the site contaminant sources. This presentation will discuss some recent studies characterizing urban background and explore case studies that demonstrate the spectrum of ramifications of urban background on the remedial action process. The focus will be on priority pollutant polycyclic aromatic hydrocarbons (PAHs) and metals, which have been the focus of the author's own evaluations, and which have been the recent focus of urban investigations by Region 4 of the U.S. Environmental Protection Agency. Some of the ramifications to be demonstrated by the case studies include 1) the effects of urban background on site investigation design, 2) the effects of background on risk assessments performed to address potential human health and ecological risks, and 3) the effects of urban background on the ultimate remedial footprint selected for remedial action. Lastly, a path forward will be proposed for future work that needs to be completed to better address the ramifications of urban background in regulatory policy-making.

## Canadian Oil Sands: Advancing Science in Chemical and Toxicological Characterization, Reclamation and Monitoring

### WP143 A model of contaminant removal from oil sands process-affected water in the Kearl treatment wetland

*A. Cancelli, F. Gobas, Simon Fraser University / Resource & Environmental Management*

Large volumes of Oil Sands Process-affected Water (OSPW) are produced by the Canadian Oil Sands during bitumen extraction. The safe management of this OSPW poses a challenge to industry operations since no discharge of this wastewater is permitted at this time. OSPW is therefore stored in large tailings ponds while industry continues to search and develop feasible and effective solutions to manage this wastewater. One potential solution is to remediate OSPW through passive treatment with treatment wetlands. These systems have been successful at remediating municipal and domestic wastewater, animal wastewater, mine water, industrial wastewater, urban storm water, field runoff, and leachate. The Kearl Treatment Wetland (KTW) is a 1 ha surface-flow treatment wetland containing 3 deep pool and 3 shallow areas, and located on Imperial's Kearl Oil Sands site in northern Alberta, Canada. In this study, we investigate the removal of polycyclic aromatic hydrocarbons (PAHs) using polyethylene samplers (PES) that were deployed in the inlet and outlet of the KTW for two consecutive deployments (July 21 – August 29, 2017, and August 29 – September 29, 2017). The performance of the treatment wetland was evaluated using these estimates of the freely dissolved PAH concentrations at the inlet and the outlet of the KTW. These data were also used test and calibrate a previously developed and parameterized contaminant-fate treatment wetland model that estimates contaminant removal via various biogeochemical processes (volatilization, transpiration, microbial degradation, plant-enzyme biotransformation, sorption to rooting media, burial). There was a consistent decline in analyte concentrations throughout the KTW during both deployments. There was a greater average change ($p < 0.05$) in concentration of contaminants measured in deployment 1 (71.7%, SD 24.2%; n = 20) compared to deployment 2 (39.1%, SD 32.1%; n = 27) resulting from changes to environmental conditions (i.e. precipitation, evapotranspiration, temperature). Model calibration resulted in an overall model bias of 1.02 (95% CI 0.75 – 1.39) suggesting a strong fit of the model estimates and the empirical data. The calibrated model showed that a log $K_{OW}$ (octanol-water partition coefficient) of 3.5 – 5.5 and a log $K_{OA}$ (octanol-air partition coefficient) less than 5.0 result in the highest removal efficiencies through the KTW.

**WP145 Assessment of liver tumor incidence in white sucker collected to determine baseline fish health in the Alberta Oil Sands area**

*M.E. McMaster, Environment and Climate Change Canada / Water and Science Technology / Aquatic Contaminants Research Division; C.J. Bennett, Environment Climate Change Canada / Water Science and Technology; J. Cunningham, Environment and Climate Change Canada / Aquatic Contaminants Research Division; T. Clark, Environment and Climate Change Canada / Water and Science Technology / Aquatic Contaminants Research Division; G. Tetreault, Enviroment Canada / Water Science and Technology; M. Evans, Environment and Climate Change Canada / Water, Science and Technology; G. Marty, British Columbia Ministry of Agriculture / Animal Health Centre*

In 1987, the International Joint Commission identified 43 Areas of Concern (AOC) in the US/Canadian Great Lakes. To qualify as an AOC, the area contained one or more beneficial use impairment (BUI). One of the BUIs identified at a number of locations was fish tumors or other deformities. It was defined as when the inciidence rates of liver tumors or other deformities exceed rates at unimpacted control sites or when survey data confirms the presence of neoplastic or preneoplastic liver tumors in bullheads or suckers. As part of the Joint Canada-Alberta Oil Sands Monitoring Program (JOSMP), fish health within the Athabasca watershed is being evaluated using methods developed for the Canadian Environmental Effects Monitoring programs. On the Athabasca River mainstem, white sucker have been selected as a large bodied sentinel species and 3 years of baseline fish health data has been collected at five sites. During these collections, liver samples were preserved for liver tumor assessment similar to those for the Great Lakes AOC. With three years of sampling 20 males and 20 females for fish health from each site, a sample size large enough to evaluate liver tumor incidence and potential increases due to exposure to natural oil sands compounds from the outcrops of the deposit or potential increase incidence due to increased development could be assessed. As part of the increased geographical extent of the JOSMP program, white sucker were also collected from Lake Athabasca during the fall of 2015 and sampled for liver tumor assessment. Samples were processed in the Environment and Climate Change histological laboratory and final assessment of the slides by the Animal Health Center of the British Columbia Ministry of Agriculture. Final results are still being collected and assessed, but liver tumor incidence will be compared between fish collected at reference sites upstream outside of the oil sands deposit, within the deposit upstream of development, in the deposit downstream of development, from Lake Athabasca further downstream and to reference fish collected within the Great Lakes. PAH data from muscle and liver from a limited number of these fish from these sites will also be presented along with hepatic mixed function oxygenase activity as an indicator of exposure of these fish to PAH related compounds.

**WP146 Development of Aquatic Environment Monitoring Triggers for the Lower Athabasca River**

*B.W. Kilgour, L. Hamilton, C. Proulx, K. Somers, Kilgour & Associates Ltd.; K.R. Munkittrick, Wilfrid Laurier University / Biology; T. Arciszewski, Alberta Energy Regulator*

Oil sands companies currently do not release process affected water to receiving environments, but there is a need and desire to do so in the future. Release of depressurization water is currently limited, but has shown no measurable changes in the receiving environment where this practice has been ongoing since 2008. There are concerns about the potential for effects of the discharge of process waters to the Athabasca River. Environmental Effects Monitoring (EEM) provides a mechanism to test predictions about the potential effects of effluent releases. EEM programs are currently in place for metal mining and pulp and paper sectors in Canada, and have demonstrable efficacy at quantifying effects and identifying potential effluent-related causes of effects. Fish populations have been extensively monitored in the mainstem of the Athabasca River under the historical Regional Aquatics Monitoring Program (RAMP) and the Joint Oil Sands Monitoring Program (JOSMP). Those data can be used as a baseline to judge the potential effects of future process water releases from oil sands operations. The results herein originated from the compilation of fish population (Trout Perch) data that were collected under RAMP and JOSMP from 2009 through 2015. Normal ranges of various measures of fish population performance were modeled in relation to river discharge and air temperature. The resulting models were statistically significant and ecologically meaningful, and thus, provide predictions or forecasts of future conditions for monitoring the potential effects of point-source discharges to the Athabasca River.

**WP147 In vitro assessment of pH-dependent uptake and toxicity of ionizable organic chemicals in fish**

*M. Brinkmann, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre; H. Alharbi, University of Saskatchewan / Toxicology Centre; S. Wiseman, University of Lethbridge / Biology; S. Sura, University of Saskatchewan / Toxicology Centre; G. Morandi, University of Saskatchewan / Department of Veterinary and Biomedical Sciences and Toxicology Centre; H. Peng, University of Saskatchewan / Department of Chemistry; J. Giesy, University of Saskatchewan / Department of Veterinary and Biomedical Sciences and Toxicology Centre; P.D. Jones, M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre*

Uptake and effects of ionizable organic chemicals in fish can significantly differ as a function of ambient pH. These differences are driven by the rate of passive diffusion of the uncharged species across the gill epithelium, which is considerably greater than that of charged species. Consequently, the flux of chemicals will peak at different pH values depending on their acid dissociation constants. Here, we propose a rapid in vitro screening method to assess the pH-dependent uptake of ionizable organic chemicals, specifically weak acids, at the fish gill. To this end, the permanent rainbow trout gill cell line RTgill-W1 was grown in transwell tissue culture inserts for two to three weeks, and allowed to establish tight monolayers as characterized by stable transepithelial electrical resistance (TEER). After acclimatization to the reduced complexity exposure medium L15/ex at pH 6.0, 7.4, or 8.5, the permeation of chemicals from apical to basal transwell chambers was determined during a 24-h exposure period by means of liquid chromatography with high resolution mass spectrometry (LC-HRMS). The neutral red retention assay was conducted prior to exposures to exclude interference of cytotoxicity with the measurements. The assay was then used to investigate individual model chemicals (chlorophenols, carboxylic acids) and a technical mixture (nonylphenol) that had been previously shown to cause pH-dependent toxicity. To explore the applicability domain of the assay, we chose to investigate the pH-dependent permeation of chemicals present in acidic, neutral, and basic fractions, as well as reconstituted total extracts of oil sands process-affected water (OSPW). The acute toxicity of OSPWs has been shown to be mostly associated with the acidic fraction, specifically naphthenic acids. We observed a substantial pH-dependency of the cytotoxicity and permeability of weak acids, as well as the acidic fraction and reconstituted total extract of OSPW. We conclude that our in vitro assay can be used to screen for pH-dependent uptake and toxicity of ionizable organic chemicals in fish. It is intended to validate the test for application to prediction of pH-dependent uptake and effects in vivo. Thus, it may be a highly valuable tool for in vitro-in vivo extrapolation, and prioritization of chemicals in non-target chemical screenings.

**WP148 RNA-sequencing to identify effects of oil sands process-affected water in chronically exposed *Daphnia magna***

*M. Houde, Environment and Climate Change Canada / Aquatic Contaminants Research Division; M. Giraudo, M. Rudy, S.D. Campbell, Environment and Climate Change Canada; R. Frank, Environment Canada / ACRD*

Extensive research has been conducted on the acute toxicity of bitumen-influenced waters and the organic mixtures therein, with assessment of multiple endpoints from organisms of varying taxa. However, there has been a paucity of research focused on sub-lethal or chronic endpoints. Assessment of toxicity endpoints other than acute lethality will provide data of great importance to initiatives intent on monitoring and reclamation within the oil sands region. In the present study, next-generation RNA-sequencing was used to identify biological pathways impacted by the chronic exposure of the model organism *Daphnia magna* to different oil sands process-affected water (OSPW) extracts. One groundwater sample with a solely natural bitumen influence, and a second groundwater sample with a combination of influences from natural bitumen and OSPW, were collected from within the McMurray oil sand formation and fractionated utilizing differences in polarity in an effects-directed analysis approach. Lethality was not observed in 48-h acute assays with *D. magna* assessing the toxicity of soluble organic fractions from different bitumen-influenced groundwaters at 100% whole water equivalents (WWE). Chronic 21-d exposures were conducted for all primary fractions at 25% WWE to ensure survival throughout the duration of the test and to avoid unspecific stress-related gene transcription profiles. Total RNA was extracted from daphnids at the end of exposure and RNA-sequencing of 75 bp paired-end reads performed using an Illumina MiSeq instrument. *De novo* transcriptome assembly and statistical analysis were done using CLC Genomics Workbench pipeline. Quantitative PCR analyses will be conducted to validate the genomic data and cellular markers of interest will be identified, analyzed and compared between fractions. The use of this high throughput technology will help identify potential pathways affected by exposure to OSPW and help align future effect research in aquatic organisms.

**WP149 The impacts of diluted bitumen oil spills on freshwater phytoplankton communities**

*J. Cederwall, Queens University / Biology; J.M. Blais, University of Ottawa / Biology; M.L. Hanson, University of Manitoba / Department of Environment and Geography; S. Higgins, IISD Experimental Lakes Area; A.C. Ortmann, Fisheries and Oceans Canada; J. Rodriguez Gil, University of Ottawa / Department of Biology; R. Rooney, University of Waterloo; A. Zastepa, Environment and Climate Change Canada; D.M. Orihel, Queens University / Department of Biology / School of Environmental Studies*

The impacts of unconventional oil spills in fresh waters are currently poorly understood at the ecosystem-level. New oil pipelines have been proposed across North America to bring diluted bitumen (dilbit), a heavy crude oil diluted with light gas condensates to facilitate transport through pipelines, from the Canadian oil sands region to refineries and other markets. These pipelines span a large geographic area, and in many cases, transverse or come into close proximity of inland water bodies. However, it is unclear how an accidental dilbit spill will affect these freshwater ecosystems. As part of the collaborative BOREAL (Boreal lake Oil Release Experiment by Additions to Limnocorrals) research project, we seek to give a comprehensive picture of the environmental fate of dilbit, its impacts on ecosystem structure and function, and its toxicity to higher trophic levels within a boreal lake ecosystem. At the IISD-Experimental Lake Area in north-western Ontario, Canada, we installed a series of nine limnocorrals (10-m in diameter and 2-m deep) in the littoral zone of a remote lake to test how dilbit affects freshwater ecosystems across a range of environmentally realistic dilbit spill volumes (ranging from 1:100,000 to 1:1,000 oil-to-water ratios). In this subproject, we examined how these experimental dilbit spills affected the structure and function of the phytoplankton community, which constituent an important component of the ecosystem at the base of the aquatic food web. To assess whether dilbit reduced algal biomass, we tracked chlorophyll *a* and flow cytometry for over 10 weeks post-spill. At the same time, we tracked changes in phytoplankton community structure by assessing samples using light microscopy (to species). Finally, we assessed primary production through dissolved oxygen concentrations and Pulse-Amplitude-Modulation to test for impaired photosynthesis via photosystem II. This research will advance our scientific understanding of the effects of unconventional oil in fresh waters and we anticipate our findings will be used by policy makers to develop safe dilbit transportation policies and for consideration in environmental monitoring and remediation strategies.

**WP150 Effects of diluted bitumen on wild small-bodied fish: A freshwater mesocosm study at IISD-Experimental Lakes Area, Northwestern Ontario**

*L. Timlick, University of Manitoba / Department of Environment and Geography; J. Séguin, J.M. Blais, University of Ottawa / Biology; M.L. Hanson, University of Manitoba / Environment and Geography; D. Orihel, Queens University; J. Rodriguez Gil, University of Ottawa / Department of Biology; V. Palace, IISD-Experimental Lakes Area*

A collaborative field study examining the fate, behaviour, and potential toxicological effects of diluted bitumen (dilbit) in fresh water began in 2018 in a boreal lake at the IISD-Experimental Lakes Area (Ontario, Canada). The Boreal lake Oil Release Experiment by Additions to Limnocorrals (BOREAL) project examines model spills of dilbit in seven littoral mesocosms (10m diameter, ~157,000 L volumes) to achieve dilutions ranging from 1:100,000 to 1:1,000 (dilbit:water). Two additional mesocosms, not treated with dilbit, were included as controls. Here we report the effects of chronic exposure (>21 days) on free-swimming, wild finescale dace (*Phoxinus neogaeus*). Exposure was determined by measuring polycyclic aromatic hydrocarbons (PAHs) in tissues and metabolites in the bile. Adult male and female finescale dace were exposed in order to assess reproductive health, while juveniles were included to assess growth. Both life stages were used to assess physiological and molecular responses to dilbit. Assessed metrics of reproductive health and metabolism include calculation of male and female gonadal somatic indices, egg diameter, histological development of gonads in both sexes, and condition factor. Gill and liver histology were examined as well as molecular markers (CYP1A, GST, soc1). Oxidative stress was determined by measuring isoprostane concentrations in tissues. The BOREAL study provides toxicological effects data from the first controlled in situ ecosystem level exposure of dilbit in freshwater.

**WP151 Sublethal Cardiac and Metabolic Effects of Crude Oil in Fathead Minnow (*Pimephales promelas*)**

*D. April, University of Saskatchewan / Toxicology Centre / Veterinary Biomedical Sciences; D.M. Janz, University of Saskatchewan / Veterinary Biomedical Sciences; V. Palace, IISD-Experimental Lakes Area; L.P. Weber, University of Saskatchewan / Veterinary Biomedical Sciences*

Transport of petroleum products in Canada is becoming an increasing public and political concern, in part due to the potential for unintended impacts on aquatic ecosystems. These concerns have necessitated further study, as the current understanding of petroleum toxicity is limited in a number of ways. Specifically, much of the existing research is focused on characterizing early life-stage developmental toxicity, however limited evidence suggests that there may also be sublethal effects on cardiac and metabolic endpoints in adult fish exposed to crude oil. Such effects can potentially impact fish populations by adversely affecting predator avoidance, reproductive success, and overall fitness. Additionally, much of the existing research has focused on specific fractions of petroleum products as opposed to characterizing toxicity of whole compounds. Petroleum compounds are complex mixtures of polycyclic aromatic hydrocarbons, naphthenic acids, and other potential toxicants; so it is crucial to examine the effects of these compounds as they would occur if released to the environment. The aim of this research is to address some of these gaps identified in the literature by examining sublethal cardiac and metabolic effects in individuals of a native fish species (Pimephales promelas) that were sub-acutely exposed to environmentally relevant concentrations of a whole-compound Canadian crude oil. A water accommodated fraction (WAF) of crude oil was prepared by mechanical dispersion and used to dose receiving waters, simulating exposure resulting from an aquatic spill. Fish were then exposed to concentrations of either 0% (Control) 0.3%, 3%, or 30% WAF for 7 days in a static 48 hr renewal protocol. Following the exposure, cardiac structure and function was assessed using ultrahigh-resolution B-mode and pulse-wave Doppler ultrasound. A second parallel set of exposures was carried out under the same parameters in order to assess fish for swim performance and standard metabolic rate (SMR). Swim performance was assessed using swim tunnel respirometry, whereas SMR was assessed using intermittent flow respirometry. The results of this research will add to our understanding of sublethal toxicities of complex petroleum mixtures to adult fishes. Future work will focus on characterization of diluted bitumen toxicity, as well as comparison of the results between the two studies.

**WP152 Impacts of Petroleum Toxicity on Marine Mammals, Reptiles, and Fish: A Review**

*E.J. Ruberg, T.D. Williams, Simon Fraser University / Department of Biological Sciences; J.E. Elliott, Environment Canada / Science and Technology Branch Ecotoxicology and Wildlife Health Division*

With the continuing potential for increased shipment of both conventional crude oil and unconventional petroleum like diluted bitumen out of the port of Vancouver, there is a need to assess the toxicological consequences of chronic or catastrophic petroleum spillage on the marine wildlife of Canada's Pacific coast. Currently there are only a handful of papers in the peer reviewed literature on the effects of diluted bitumen on marine wildlife. Additionally, there is a need for a current and comprehensive literature review of petroleum toxicity on marine wildlife prior to planning further research. Our review aims to summarize information gathered from petroleum toxicity and determine what can be applied to diluted bitumen toxicity. The focus will be on marine vertebrates, specifically mammals, reptiles, and to summarize and update a 2015 review on fish. Effects consist of both lethal and sublethal endpoints including gene expression, physiology, and fitness. A search was conducted on the Web of Science database, using search parameters for papers from 1900 to 2018, with no filters applied. Papers examining a single component of petroleum (e.g. pyrene, cadmium) were excluded from the search. The majority of papers were on effects of oil spills, as well as laboratory studies conducting exposures of PAHs, components of petroleum, or a petroleum product on marine vertebrates. The results of this literature review will help inform academics, researchers, and policy makers on how to better protect B.C.'s marine wildlife from oil spills.

**WP153 Developing reference materials for advancing chemical and toxicological characterization of soluble organics in oil sands process-affected waters**

*R. Frank, Environment Canada / ACRD; H. Malle, R. Strub, Environment and Climate Change Canada; S. Rowland, University of Plymouth / School of Geography Earth and Environmental Sciences; V. Snieckus, Snieckus Innovations; M. Rudy, S.D. Campbell, R. Vanderveen, Environment and Climate Change Canada; M. Hewitt, Environment and Climate Change Canada / Canada Centre Inland Waters*

Advanced separation and high resolution mass spectrometry methodologies have allowed for significant advancement in the understanding of the chemical composition of the complex organic mixtures within oil sands process-affected water (OSPW) and other bitumen-influenced waters over the past 10 years. However, quantitative assessment of the mixture components has remained unreliable due to the absence of relevant reference materials. Quantitative analysis of these complex organic mixtures is vital for monitoring and reclamation research initiatives as currently there are no definitive means to accurately establish water quality guidelines from toxicological assays nor can the quantity of tailings migration be accurately assessed. To address this need, current research is underway to develop certified reference materials (CRM) for use in chemical and toxicological characterizations of OSPW-derived organics. These CRMs include synthesized individual reference compounds as well as comprehensive mixtures of extracted OSPW-derived soluble organic compounds. Recent collection of active OSPW samples was coordinated through Canada's Oil Sands Innovation Alliance (COSIA) and provided >100L water from each of 9 different active OSPW containments, with several collections taking place over multiple locations throughout the sampled tailings pond. This variable sampling will allow for the creation of a comprehensive CRM mixture of soluble organics found within active OSPW containments, and will also allow for a thorough investigation of the chemical variability that exists within and between OSPW sources.

**WP154 Naphthenic Acid Diagnostic Ratio Analysis; a New Approach for Identification of Alberta Oil Sands Process-Affected Water and Environmental Monitoring**

*P. Brunswick, Environment and Climate Change Canada / Pacific and Yukon Laboratory for Environmental Testing; M. Hewitt, Environment and Climate Change Canada / Canada Centre Inland Waters; R. Frank, Environment and Climate Change Canada; G.C. van Aggelen, D. Shang, Environment and Climate Change Canada / Pacific and Yukon Laboratory for Environmental Testing*

A new approach to environmental monitoring of the naphthenic acids, sourced from oil sands tailings containment ponds, is proposed using relative percent difference ratios. The oil sands process water (OSPW) tailings are high in these persistent organic compounds that have been under review because of their high toxicity. The proximity of the ponds to waterways and aquafers is a source of environmental concern, and there is a need for procedures that distinguish anthropogenic seepage from natural sources of naphthenic acids. The authors propose a novel biomarker ratio analysis of data collected during LC/QToF quantitative analysis. The analytical method identifies compounds to ≤5 ppm mass accuracy by formula and was adapted to include heteroatomic sulfur containing homologues. Responses for selected biomarkers were compared in ratio by relative percent difference, in a similar manner to that relied upon internationally for forensic oil spill analysis. These diagnostic forensics allowed for the comparison between duplicate samples both graphically and by relative %Difference. No interferences have been observed for surface and groundwater control samples. Based on the currently selected biomarker ratios, OSPW samples from different industrial sites could be identified as a definitive "no match" result, while those from within one industrial site were a "match". Temporal OSPW samples taken at different times from the same site showed a "match" over the short term but not over one year. The rapidity of this diagnostic ratio calculation and simplicity of visual presentation, in addition to its ability to set values on the relative %Difference results for "match", "probable match", or "no match", make it an excellent potential tool for regulatory purposes. Observed relative %Differences for currently selected biomarkers will be discussed, with the aim of proposing a new procedure for the future environmental monitoring of naphthenic acid seepage, spill, or breach.

**WP155 Evaluating the roles dissolved and particulate fractions of eroding natural oil sands in Athabasca Rivers using water accumulated fractions**

*A. Cude, University of Waterloo / Department of Biology; S. Birks, InnoTech Alberta / Water Management; C. Lu, University of Waterloo / Biology; A. Pereira, InnoTech Alberta / Environmental Analytical Services; G. Dixon, University of Waterloo / Department of Biology*

In the tributaries and mainstem of the Athabasca River in the oil sands region, inputs of bitumen-derived constituents from natural oil sands as well as potential contaminants associated with mining activities will affect water quality, thus raising concerns of cumulative impacts on aquatic organisms. The partitioning of bitumen-derived constituents into air, water and sediment during natural erosion influences the exposure to and effects of constituents on aquatic organisms. There is a need to better understand the environmental impacts associated with bitumen-derived constituents as a function of erosional processes in order to address the issue of potential cumulative impacts. The objective of this study was to isolate the dissolved and particulate fractions of bitumen ore mixed with water and evaluate the toxicity of the individual and combined fractions on the survival of *Hyalella azteca*. Two bitumen ore samples were evaluated; 1) bitumen ore collected from a McMurray Formation exposure in the MacKay River valley and 2) bitumen ore collected from an open pit mine and stored at the InnoTech Sample Bank. Bitumen ore was mechanical mixed for 24 h in water to simulate erosion, and then filtered to separate the dissolved and particulate fractions. Toxicity tests were conducted using a 96-h *H. azteca* survival test at bitumen concentrations of 0-2.5 dry wt g/L for four different treatments: bitumen ore (unmixed), bitumen ore (mixed), dissolved fraction and particulate fraction. The results for both bitumen ore samples indicate significantly higher toxicity for all treatments that contain particulates relative to the dissolved fraction. Water chemistry analyses of metals and polycyclic aromatic compounds (PAC) were used to estimate threshold concentrations. Threshold concentrations were compared with available data on environmental concentrations of metals and PACs in suspended sediments collected from the Athabasca River. Interestingly, within the age range (2- to 9-day old) of neonates recommended for testing (Environment Canada, 2013), it appears that younger neonates (2- to 4-day) are more sensitive to fine particulates than older neonates (7- to 9-day old) in 96 h water exposures. The findings of this study are important to establishing a comprehensive environmental monitoring program and developing an effective watershed management strategy in the oil sand region.

**WP156 Comprehensive two-dimensional gas chromatography mass spectrometry for the analysis of substituted and unsubstituted polycyclic aromatic compounds**

*I.G. Idowu, W. Johnson, University of Manitoba / Chemistry; O. Francisco, University of Manitoba; T. Obal, Maxxam Analytics International Corporation / Scientific Services; C. Mavin, Environment and Climate Change Canada; P. Thomas, Environment and Climate Change Canada / National Wildlife Research Centre; C. Sandau, Chemistry Matters; J. Stetefeld, University of Manitoba / Chemistry; G. Tomy, University of Manitoba / Department of Chemistry*

Alkylated polycyclic aromatic compounds (APACs) are a complex class of environmental contaminants that are ubiquitous and known to be toxic. Each PAC group consists of multiple compounds and the number of theoretically possible isomers can reach into the thousands. Currently, each PAC group is quantified collectively as a single group of compounds. However, individual PACs can reveal important information on how the PACs were formed and this information may be used to determine sources of PACs in samples, potentially even for similar PAC sources. To date, one-dimensional gas chromatography (GC) has been used to characterize the profile of these compounds in the environment. It is hypothesized that many of the limitations with the 1D GC approach to characterizing APACs can be circumvented using GC×GC. Here we apply comprehensive two-dimensional GC coupled to high-resolution time of flight mass spectrometry (GC×GC-HFTOF/MS) to aid in the separation, identification and quantitation of APACs in three environmental matrices: mussel tissue (*Mytilus edulis*), lubricating oil and coal. In the absence of authentic analytical standards, differences in the mass spectral fragmentation pattern of isomers were used to confirm the identity of isomers within a PAC group. A detailed diagnostic characterization of each PAC grouping in the 3 environmental samples is presented. The GC×GC-HFTOF/MS method was validated according to the EURACHEM guidelines and used to quantify a biological standard reference material (SRM 2974a) from the National Institute of Standards and Technology. The method met all the standard method performance requirements such as trueness, precision and measurement of uncertainty and is fit for quantifying these compounds in biota. Furthermore, the method was used to identify and quantify additional PAC compounds in the SRM 2974a material which to date have not been certified. With appropriate statistical analytical tools, the described GC×GC method can be used as a tool for more robust source fingerprinting and source apportionment of PACs in the environment.

**WP157 Identification of Halogenated Polycyclic Aromatic Compounds in Biological Samples from Alberta Oil-Sands Region**

*Z. Xia, I.G. Idowu, University of Manitoba / Chemistry; C. Marvin, Environment and Climate Change Canada / Aquatic Contaminants Research Division; P. Thomas, Environment and Climate Change Canada / National Wildlife Research Centre; W. Johnson, O. Francisco, J. Stetefeld, G. Tomy, University of Manitoba / Department of Chemistry; B. Crimmins, Clarkson University / Civil and Environmental Engineering*

Halogenated polycyclic aromatic compounds (HPACs) were identified in biological samples from the Alberta Oil-Sands Region (AOSR) using gas chromatography high-resolution time-of-flight mass spectrometry (GC-HRTOF-MS) at a resolving power of 25,000. Knowledge of the electron ionization (EI) fragmentation behavior of individual HPAC isomers, achieved by injecting authentic standards in full-scan MS mode, was paramount in identifying a suite of HPACs in samples from the AOSR. Numerous compounds were detected in the high resolution total ion chromatogram in the extracts of 4 biological species from the AOSR: river otter livers (*Lutra Canadensis*) and muscle tissue of northern pike muscle tissue (*Esox lucius*), snails (*Gastropoda*) and lake whitefish (*Coregonus clupeaformis*), many of which remain unidentified. However, careful examination of the high-resolution accurate mass data and retention times ($r_t$), suggest that 3 HPACs were positively identified in our AOSR samples. Dichloro-anthracene/phenanthrene, bromo-anthracene/phenanthrene and dibromo-fluorene were identified based on their $r_t$ and the measured mass accuracy (± 3ppm) of 2 characteristic ions prominent in their EI mass spectra. Lipid corrected concentrations of the mono- and dibromo-PACs were estimated to be *ca*. 170.5 and 111.4 ng/g in snails while concentrations of the dichloro-PACs was significantly smaller in lake whitefish and river otter.

**WP158 Determination of Polycyclic Aromatic Hydrocarbons in Surface Water using Simplified Liquid-Liquid Micro-Extraction and Pseudo-MRM GC/MS/MS**

*H. Kwok, Environment and Climate Change Canada / Pacific Environmental Science Centre; J. Yan, P. Brunswick, Environment and Climate Change Canada / Pacific and Yukon Laboratory for Environmental Testing; M. Haberl, CARO Analytical Services; G. Park, C. MacInnis, T. Nguyen, L. Chow, G.C. van Aggelen, D. Shang, Environment and Climate Change Canada / Pacific and Yukon Laboratory for Environmental Testing*

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous pollutants found throughout the environment, formed from natural and anthropogenic incomplete combustion such as forest fires and burning of fossil fuels. The monitoring of PAH concentration in surface water is a crucial part of water quality surveillance programs implemented by government agencies. In cases of accidental oil spills, PAH analysis is an important tool for rapid spill source identification and environmental impact assessment. The solubility of PAHs in water is very low; therefore extraction typically requires a complex procedure with large volumes of water and extraction solvent to achieve trace level detection and quantitation. This liquid–liquid micro-extraction (LLME) GC/MS/MS approach sought to simplify the classic liquid-liquid extraction technique and optimize instrument performance for analysis of 18 PAHs in surface water. This LLME method utilizes a pseudo multiple reaction monitoring (PMRM) mode, a technique in which the third quadrupole monitors the same m/z as for the first quadrupole precursor ion. The use of helium as the only collision gas improved the sensitivity by significantly reducing both PAH compound fragmentation and baseline noise. For PAH determination, the PMRM approach proved superior to the classical quadrupole MRM technique in terms of enhanced sensitivity. With observed improvements in sensitivity, micro-extraction using only 4 mL of a novel binary solvent became possible, with corresponding reduction in time consuming sample preparation procedures and toxic solvent usage. Quantifying and qualifying ions, in addition to retention times, were used to verify trace level PAHs. During method validation, the limit of quantitation (LOQ) in surface water was observed to be 10 $ngL^{-1}$ for the target PAHs. The recovery of individual PAHs was in the range of 80 to 114% from a surface water matrix, with a corresponding precision between 1.4 and 4.8% RSD. The robustness and accuracy of this method was demonstrated by its success in repeated proficiency test studies and during routine use in environmental sample testing. Analysis of chemically enhanced water accommodated fraction (CEWAF) samples from toxicological LC50 bioassays has proven its applicability in the presence of crude oil and oil spill dispersants.

**WP159 Source identification of nitrogen heterocyclic polycyclic aromatic compounds in snow, sediment, and air samples from the Oil Sands Area of Alberta**

*L. Chibwe, Environment and Climate Change Canada / Aquatic Contaminants Research Division; C.A. Manzano, Universidad de Chile / Department of Chemistry; D.C. Muir, B. Atkinson, Environment and Climate Change Canada / Aquatic Contaminants Research Division; J. Kirk, Environment and Climate Change Canada / Global Tox; C. Marvin, C. Teixeira, Environment and Climate Change Canada / Aquatic Contaminants Research Division; D. Shang, Environment and Climate Change Canada / Pacific and Yukon Laboratory for Environmental Testing; T. Harner, Environment and Climate Change Canada / Air Quality Research Division*

The Athabasca Oil Sands (AOS) deposits located in Northern Alberta, Canada, are considered the world's third largest oil reserve. Long-term data sets on major contaminants, such as polycyclic aromatic compounds (PACs), have been gathered in the past few years as part of the Alberta-Canada Joint Oil Sands Monitoring program, initiated in 2012. Potential sources of PACs in the AOS area include natural erosion of geological formations, forest fires, bitumen upgrading, diesel combustion, and airborne dust from roads and mining operations. Focus has been limited on a list of mostly unsubstituted PACs, even though over 200 sulphur-containing PACs were recently identified in AOS environmental samples. This study was designed to explore nitrogen heterocyclic PAC isomers (NPACs) currently not being monitored in snowpack, lake sediment and passive air samples collected at varying distances from the main AOS developments during 2014-2015. Additionally, source samples including petroleum coke (pet coke), haul road dust, and unprocessed oil sands were also analyzed. All samples were analyzed using two-dimensional gas chromatography with time-of-flight mass spectrometry (GC×GC/ToF-MS). Over 200 NPACs were identified and classified into at least 18 isomer groups, including *c1*-carbazoles, *c2*-carbazoles, *c3*-carbazoles and benzocarbazoles, based on their mass spectra and their location in the 2D-chromatogram. Relative concentrations of the NPACs decreased with distance from the main developments, and with increasing depth of lake sediments, but were detected at least 50 km of the major developments. Additionally, pet coke had a more distinct distribution compared to the road dust and unprocessed oil sands ores and was similar to the near-field environmental samples. These results suggest that pet coke is a potential source for the identified NPACs in near-field sites, and that these compounds have the potential to be used as source indicators for future research in the AOS area.

**WP160 Source apportionment of PAHs in snow and lake sediments in the Athabasca oil sands region using stable and radiocarbon isotopes**

*J.M. Ahad, Natural Resources Canada / Geological Survey of Canada; H. Pakdel, Institut National de la Recherche Scientifique / Centre Eau Terre Environnement; P.R. Gammon, M.M. Savard, Natural Resources Canada / Geological Survey of Canada*

Previous work has demonstrated the potential of compound-specific stable and radiocarbon isotope analysis to delineate sources of polycyclic aromatic hydrocarbons (PAHs) in Canada's oil sands region [1-4]. In this study, compound-specific stable carbon ($\delta^{13}C$) and hydrogen ($\delta^{2}H$) isotope analyses were carried out on PAHs in sediment cores collected from two lakes in the Athabasca oil sands region (AOSR): one located close to the geographic centre of surface mining operations, and the other situated close to a large steam-assisted gravity drainage (SAGD) facility. Compound-specific isotope ratios of PAHs and radiocarbon ($^{14}C$) contents of solvent-extractable organics in snow particulates deposited on the ice-covered surfaces of fourteen lakes across the AOSR were also determined to quantify the contribution of anthropogenic dust transported directly to these ecosystems. Radiocarbon isotope ratios indicated a significant contribution (up to ~ 80%) of petrogenic or fossil (i.e., $\Delta^{14}C$ = -1000‰) carbon in snowpack dust at some sites. More negative $\Delta^{14}C$ values were found in samples closer to the geographic centre of AOSR mining operations and containing higher levels of particulate matter and PAHs. Stable carbon and hydrogen isotope ratios pointed to petroleum coke (petcoke) as a major source of PAHs (over 90% contribution at several sites) at lakes closest to the mining operations, with forest fire contributions becoming increasingly more significant (up to 100%) at greater distances. The information obtained by isotopic analysis provides the high level of quantitative PAH source apportionment required for effective environmental management practices in the AOSR.

## Evolutionary Ecotoxicology Then and Now: Decades of Progress in the Science of Evolution to Pollutants

**WP161 Can epigenetic transgenerational inheritance be incorporated into ecological risk assessment frameworks?**

*J. Shaw, CSIRO / Land and Water*

Incorporating transgenerational effects into risk assessment procedures has been previously suggested. However, a review of existing literature indicated that contaminant-induced transgenerational inheritance may be less common than reported. Our literature search identified numerous studies claiming transgenerational impacts, but with little compelling evidence. Therefore, we identified a need for more robust multi-generation epigenetic studies that can adequately evaluate transgenerational inheritance. Specifically, experiments that extend beyond what could be deemed "direct exposure" to F1 and F2 gametes, and also experiments that include subsequent non-exposed generations to evaluate transgenerational recovery times. Also, appropriate experimental replication is required to account for the highly variable nature of epigenetic responses and to address the apparent irreproducibility of current studies. Studies are also needed to correlate epigenetic end points with observable detrimental organism changes before a need for risk management can be properly determined. Furthermore, epigenetics focused studies should include concentrations lower than current "$EC_{10–20}$" or "Lowest Observable Effect Concentrations" for the organism's most sensitive phenotypic end point, as evaluating the effect of higher concentrations is usually already adequately done using more inexpensive endpoints. We propose a regulatory framework and optimal experimental design that enables transgenerational epigenetic effects to be assessed and incorporated into conventional ecotoxicological testing in a more useful manner.

**WP162 Evolved resistance and aryl hydrocarbon receptor pathway gene expression in Gulf killifish (*Fundulus grandis*) from the Houston Ship Channel**

*P. Bruns, Baylor University; E.M. Oziolor, University of California, Davis / Environmental Toxicology; C.W. Matson, Baylor University / Environmental Science*

Wild populations inhabiting chronically contaminated environments may evolve resistance to the adverse effects of toxicant exposure. For example, Gulf killifish (*Fundulus grandis*) populations from highly contaminated portions of the Houston Ship Channel (HSC) have evolved resistance to the teratogenic effects of exposure to some aryl hydrocarbon receptor (AHR) agonists (*e.g.*, PAHs, PCBs). Similar resistance has been found in populations of the closely related Atlantic killifish (*F. heteroclitus*) from highly polluted sites on the Atlantic coast. In both cases, resistance is known to be associated with a recalcitrant AHR. In *F. grandis*, this recalcitrance has only been studied via CYP1A activity. However, it has been shown previously in *F. heteroclitus* that the expression levels of other CYP1 genes are not all similarly reduced in resistant fish. Differences in the relative transcriptional responsiveness of these other AHR pathway genes may play a role in the variability observed among adapted *Fundulus* populations. This study examined AHR related gene expression in *F. grandis* during developmental exposure to AHR agonists. Comparison of the results for reference and resistant populations further characterizes the molecular responses to toxicant exposure that lead to the resistance observed in HSC populations.

**WP163 Metabolomics-DNA methylation cross-talk in killifish from the New Bedford Harbor Superfund site**

*S. Bea, N. Chatterjee, University of Seoul; D. Jung, Korea Environment Institute / Institute of Health and Environment; R.T. Di Giulio, Duke University / Nicholas School of the Environment; D.E. Nacci, USEPA / Atlantic Ecology Division; D. Yoon, Pusan National University; S. Kim, Pusan National University / Department of Chemistry; J. Choi, University of Seoul / School of Environmental Engineering*

The Atlantic killifish (*Fundulus heteroclitus*) is an estuarine species that are found along the eastern coast of North America. Killifish is considered a good model species to study the adaptive response to chronic exposure to pollutants such as TCDDs, PCBs, and PAHs. Studies have shown that different populations of killifish have adapted to extremely polluted environments, including Superfund sites. One such population is the PCB-adapted population inhabiting the Superfund site at New Bedford Harbor, MA (NBH). Previous studies have shown that this population is resistant to PCB-mediated developmental toxicity. In this study, to identify whether adaptation to PCB exposure has also occurred at the epigenetic level, we investigated the global epigenetics (DNA methylation) and metabolomics and stress response gene expression in brain and liver tissues from the NBH killifish, as well as from a nearby reference site (Scorton Creek, SC). We found significant alteration of several metabolites (such as, choline, betaine, histidine, methioninemyo-Inositol, sn-Glycero-3-phosphocholine etc.) in the NBH killifish compared to the fish from reference site. Furthermore, a marked global DNA hypomethylation was evident in the NBH killifish which is clearly tissue (liver > brain) and gender (female > male) specific. Taken together, we postulate a possible metabolomics-epigenetics (DNA methylation) cross-talk in killifish due to PCB exposure. Possible involvement of this mechanism on the adaptation of killifish to PCB exposure needs to be further investigated. Acknowledgement : This work was supported by the Mid-career Researcher Program (2017R1A2B3002243) through the National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT and Future Planning.

**WP164 Overview and mechanisms of resistance in the freshwater crustacean *Hyalella azteca***

*K.M. Major, University Of Massachusetts, Boston / School for the Environment; A. Grove, Eastern Washington University / Biology; D.P. Weston, University of California / Department of Integrative Biology; M.J. Lydy, Southern Illinois University, Carbondale / Center for Fisheries Aquaculture and Aquatic Sciences; C. Higbee, J. Joyner-Matos, Eastern Washington University / Biology; H.C. Poynton, University Of Massachusetts, Boston / School for the Environment*

*Hyalella azteca* are freshwater, epibenthic amphipods widely used in environmental toxicology to study the impacts of human activities and are highly sensitive to pesticides and metals. However, resistance to a variety of pollutants have been documented in *H. azteca*, where certain populations have tolerance levels 5-1000 fold higher than sensitive individuals. For example, populations with resistance to pyrethroid and organophosphate insecticides have been found throughout urban and agricultural areas of California as well as urban areas of New England. In the chain lakes of the Coeur d'Alene River Basin in northeast Idaho, *H. azteca* have been discovered living in areas contaminated with toxic levels of Pb, Zn, Cd, As, and Cu. Amphipods from this area are also over 100 times more tolerant to Zn than sensitive laboratory populations. The goal of this research is to uncover the molecular mechanisms responsible for resistance in these populations across United States. We are drawing on examples of parallel evolution in insects and crustaceans to show that similar mechanisms of resistance evolve repeatedly. Through these studies, we are also developing molecular assays to identify resistance in natural populations, which will facilitate surveys to understand the prevalence of resistance and its correlation to other indicators of ecosystem impairment.

## Advancing the Adverse Outcome Pathway Concept for Mitochondrial Dysfunction

**WP165 The organochlorine pesticide toxaphene affects fish development and acts as a mitochondrial toxicant**

*V. Perez, University of Florida / Physiological Sciences; N. Wu, Huaiyin Normal University / School of Life Science Jiangsu / Collaborative Innovation Center of Reginal Modern Agriculture and Environmental Protection; J. Schmidt, N.D. Denslow, C.J. Martyniuk, University of Florida / Physiological Sciences*

Toxaphene is a restricted use pesticide that is produced by reacting chlorine gas with camphene. It was heavily used as a pesticide in the Lake Apopka region in Florida for agricultural purposes in the 1960's and 1970's, and today it remains elevated in the soil despite being banned fifty years ago. The objective of this study is to determine the effects of toxaphene exposure on early life stages of zebrafish, a model fish species used widely for developmental toxicity research. Zebrafish were exposed to 0.011-1.11 µg/L from 6 hours post fertilization (hpf) to 96 hpf. Significant mortality was observed in embryos exposed to toxaphene >1.11 µg/L. Deformities were noted at lower doses (>0.11 µg/L), and included edema as well as spinal and cranial deformities. As ATP production is important for development and may be related to the observed deformities, mitochondrial bioenergetics of 24 hour embryos were assessed following exposure. ZF embryos were exposed to 0, 11.1, or 111 µg/mL toxaphene (0.5% v/v DMSO) for 24 hours starting at the blastula stage (~3 hpf). Oligomycin, the uncoupler Carbonyl cyanide-4 (trifluoromethoxy) phenylhydrazone (FCCP), and sodium azide were used to challenge the mitochondria in a stress test. Embryos at 24 hpf were treated with 11.1 and 111.1 µg/L and showed lower basal respiration and lower ATP-dependent respiration compared to vehicle and water controls, suggesting that the capacity of the mitochondria to produce ATP was compromised following exposure to toxaphene. Expression of transcripts related to oxidative stress and apoptosis were also tested and normalized gene expression for caspase 3, caspase 9, superoxide dismutase 1 and superoxide dismutase 2 were not changed in relative abundance. However, heat shock protein 70 was significantly induced (more than 50-fold) in the highest treatment group, suggesting that the embryos were under a significant general stress response. We propose that altered bioenergetics in early development can result in delayed hatch and compromised survival of wild species, and studies are underway to invertigate indigenous populations of fish.

**WP166 Toxicity assessment of Tebuconazole in zebrafish (*Danio rerio*) embryos and larvae: Focus on mitochondrial bioenergetics and activity**

*V. Perez, C.L. Souders II, University of Florida / Department of Physiological Sciences; C. Tischuk, University of Florida; C.J. Martyniuk, University of Florida / Physiological Sciences*

Triazole fungicides are increasingly used in areas of the US to combat mold and fungi, in order to protect vegetables, citrus, ornamental plants and field crops. Tebuconazole is one such fungicide which is considered to be relatively non-genotoxic, however the EPA classifies this compound as a putative human carcinogen. To learn more about the potential adverse effects associated with tebuconazole in non-target aquatic organisms that inhabit areas in which agricultural run-off occurs, we exposed early life stage zebrafish to the fungicide. Zebrafish embryos at 6 hpf were exposed to 2.5, 25, 50, 100 µM tebuconazole in 0.1% v/v DMSO for 24 hours and mitochondrial performance was evaluated. Twenty-four hour old embryos treated with 100 µM showed lower basal respiration and lower spare capacity compared to vehicle controls, suggesting that the capacity of the mitochondria to produce ATP was compromised following exposure to tebuconazole. In addition, survival decreased in a dose dependent manner over 96 hours. For behavioral assays assessing dark photokinesis (0.1, 1 and 10 µM tebuconazole), 10 µM tebuconazole showed a soporific effect on larval locomotor behavior while in the light/dark preference test (0.01, 0.1 and 1 µM tebuconazole), there was some evidence that the fish spent more time in the dark, suggesting less anxiety. Future studies are focused on identifying the specific mechanisms that may explain altered bioenergetics and behavioral phenotypes following exposure to tebuconazole.

**WP167 Mitochondrial toxicants: Will parental exposure during development lead to later life and heritable effects?**

*C. Bergemann, D.F. Mello, Duke University / Nicholas School of the Environment; C. Shoben, Duke University / Biology; L. Perez, Duke University; L.R. Baugh, Duke University / Biology; J.N. Meyer, Duke University / Nicholas School of the Environment*

Chemical exposure during development can have dramatic and sustained impacts, especially if the chemicals target the mitochondrial electron transport chain. Altered mitochondria function can contribute to the initiation of metabolic and degenerative diseases. However, few studies have isolated the effects of chemical exposure during development (and prior to conception) on organisms later in life and in offspring. In this study, we used the model organism *C. elegans* which has many advantages: a fully sequenced and annotated genome, a short and well-characterized reproductive cycle, and the ability to test many individuals at once. We hypothesized that pre-conception exposure to rotenone, a widely-used pesticide and piscicide that inhibits mitochondrial respiration complex I, would result in lifelong effects and would impact the offspring. For experiments, the parental generation (P0) were exposed to rotenone (0.25 and 1 µM) or vehicle (1% DMSO; control) for 48 hours from egg hatch to the L4 larval stage. Post-exposure, animals were transferred to plates for another 48 hours and allowed to lay eggs. Preliminary data showed that after 48-hours of exposure, the P0 generation had a dose-dependent decrease in growth that continued into adulthood at 96 hours. Functional respiratory measurements in whole nematodes with the Seahorse XFe24 revealed a dose-dependent decrease in the basal oxygen consumption rate (OCR; -29.4% and -50.26%) and non-mitochondrial OCR (-19.4% and -67.7%). There was also a trend for a decrease in mitochondrial spare capacity, basal mitochondrial, and ATP linked OCR. In the progeny (F1), growth and respiration at 48 hours showed no difference between offspring from exposed and control P0 animals. Mitochondrial and nuclear DNA copy number ratio remained unaltered in either the P0 or F1 generation in all treatments. These preliminary data suggest that mitochondrial function is impaired in parental (exposed) animals but recovers in the next generation based on the parameters analyzed. Future experiments will include other mitochondrial toxicants, transcriptomics and epigenetic analysis, as well as the effect of modified caloric intake.

**WP168 Adverse effects of chemical contaminants on neurodegeneration in vitro**

*O. Odia, Texas Tech University / TIEHH / Department of Environmental Toxicology; A. Martinez, E. Smith, Texas Tech University / TIEHH*

Numerous causes of neurogenerative diseases have been associated with environmental contaminant exposures, however, due to its complex etiology, it is difficult to distinguish general neurotoxicity effects from specific neurodegenerative effects. Also, from an invitro perspective, the use of neuron astrocyte, co-cell culture to study neurodegeneration is deserving of further study since this is more realistic than contaminant exposures to a primary neuron culture in addition to the protective role of the astrocyte in normal invivo conditions. In this study, a neuron-astrocyte co-culture was used in as a realistic method to evaluate the effects of chemical contaminants on neurodegeneration from exposures of the neural stem cells to fully differentiated astrocyte neuron coculture in a model that simulates a 3 D exposure format.

**WP169 Investigating mechanisms and consequences of chemical-induced mitochondrial DNA mutagenesis**

*T. Leuthner, Duke University / Integrated Toxicology and Environmental Health; J.N. Meyer, Duke University / Nicholas School of the Environment*

Over millions of years, mitochondria have evolved careful coupling of internal chemistry with external environment to provide energy and important signaling molecules required for development and survival across many forms of life. This depends in part on the function of proteins coded in the mitochondrial genome (mtDNA). MtDNA has long been studied across fields including population genetics, evolutionary biology, and more recently, medicine and toxicology. However, the processes that regulate which mitochondrial genomes are transmitted across generations are not fully understood. I aim to identify potential homeostatic processes in the cell that help organisms defend against mtDNA damage from genotoxicants that cause mtDNA mutations that could have significantly deleterious effects on organism and population health. To do so, I exposed the model nematode, *Caenorhabditis elegans*, to various concentrations of ubiquitous pollutants and known carcinogens: cadmium (Cd) and aflatoxin $B_1$ ($AFB_1$). There is a significant dose-dependent increase in the number of lesions in the mtDNA in both Cd and $AFB_1$ treated C. elegans: from 0.05 to 0.3 lesions/10kb (1mM and 50mM of Cd respectively) and from 0.25 to 0.5 lesions/10kb (5mM and 25mM $AFB_1$ respectively). I also observe a dose-dependent decrease in fecundity. Additionally, there is a significant exacerbation of mtDNA damage in *C. elegans* mutants that are deficient in processes involved in the selective removal of damaged and defective mitochondria: *pink-1* and *dct-1* (two-fold and 1.5-fold, respectively). There is also a significant reduction in the fecundity of the mutants compared to wildtype *C. elegans*, suggesting increased susceptibility to toxicity potentially mediated via mitochondrial dysfunction. Together, the mtDNA damage and reproduction results suggest that these processes may be involved in the removal of mitochondria that have accumulated mtDNA damage. We are currently performing targeted sequencing of mtDNA in *C. elegans* after exposure to Cd and $AFB_1$ to investigate whether or not these mitochondrial homeostatic processes are necessary for removal of mtDNA damage prior to accumulation of mtDNA mutations. This is important to understand because the “footprints” that chemicals leave via specific changes in mtDNA sequences could be developed as biomarkers as well as in risk assessment, since mtDNA markers are widely used in predicting health and measuring genetic diversity of populations.

**WP170 Adverse Outcome Network Development for Acetylcholinesterase Inhibition in Zebrafish (*Danio rerio*)**

*K. Conrow, Arizona State University; N. Vinas, US Army / Engineer Research and Development Center; K.H. Watanabe, Arizona State University / School of Mathematical and Natural Sciences*

Acetylcholine (ACh) is a diverse neurotransmitter that is involved in many processes from cognition to muscle activation. The enzyme acetylcholinesterase (AChE) hydrolyzes ACh in order to eliminate it from the body, and when AChE is inhibited ACh levels increase. An excess of ACh at cholinergic synapses overstimulates both muscarinic- and nicotinic-receptors. These receptors are found in most organs in the body, thus the effects of AChE inhibition can result in multiple adverse outcomes affecting a wide variety of functions. Moreover, a wide variety of chemicals including organophosphates, carbamates and some high nitrogen compounds can inhibit AChE. AChE inhibition has a large impact, but relatively little research has been focused on developing related adverse outcome pathways (AOPs) or a network for this molecular initiating event. This presentation focuses upon the construction of adverse outcome pathways for acute symptoms of AChE inhibition in zebrafish (*Danio rerio*). Using a comprehensive literature review, we identified key upstream events essential to the development of specific pathophysiologies that include seizures, altered retinal structure, and paralysis. Applying those studies, we constructed key event relationships for the development of an AChE inhibition AOP network including identification of data needed for development of quantitative models. Preliminary AOP network results will be presented with references supporting each relationship so that we can more fully represent the wide reaching effects of AChE inhibition as a molecular initiating event.

## Ecotoxicology of Amphibians and Reptiles

**WP171 Spadefoot toads (*Spea multiplicata*) as ecological receptors for metals from uranium mine containment ponds**

*B.K. Kunz, D. Cleveland, J. Hinck, USGS / Columbia Environmental Research Center*

Containment ponds associated with breccia pipe uranium mines in the Grand Canyon watershed create surface water habitats in otherwise arid areas. These habitats attract a variety of wildlife species, including breeding spadefoot toads (*Spea multiplicata*), which opportunistically use the ponds for oviposition and larval development. Because containment pond waters contain elevated concentrations of uranium and co-occurring metals (e.g., copper, cobalt, nickel, and arsenic), *S. multiplicata* are potentially exposed to these metals for the duration of the aquatic larval period. However, it is unknown whether these chronic exposures detrimentally affect the larvae. Previous USGS studies have identified copper and cobalt as toxicity drivers for invertebrates exposed to containment pond water, but there is a general lack of ecotoxicological data on metals for *S. multiplicata*. It is also unknown whether metals bioaccumulated by *S. multiplicata* larvae are transferred into terrestrial food webs when the toads metamorphose. We conducted three types of exposures with *S. multiplicata* to evaluate the chronic toxicity and accumulation of containment pond metals by amphibians: 1) a 10-day exposure to field-collected water from a containment pond at the Canyon Mine (Arizona, USA), 2) a 10-day exposure to field-collected sediment from the same pond, and 3) 44-day single-metal exposures to copper or cobalt that lasted the duration of the larval period. All tests were conducted with newly hatched larvae. Endpoints were *S. multiplicata* survival, growth, development, and body burdens of metals. This study helps predict the consequences of breccia pipe uranium mining on native amphibian populations, and determine the potential for toad-mediated transfer of metals from mine containment ponds into surrounding habitats.

**WP172 The combined effects of pesticides and fertilizer on amphibian stress and bioaccumulation in a terrestrial environment**

*R. Van Meter, Washington College / Biology and Environmental Science; R. Adelizzi, Washington College; D. Glinski, Dublin City University*

Tank mixtures, in which multiple agrochemicals are labelled for combined application to a crop, are popular within the agricultural community because they are time- and cost-effective. However, these applications leave non-target organisms, such as amphibians, at risk of exposure to numerous, potentially harmful chemicals at the same time. Here we explore the effects of a common herbicide (atrazine and alachlor) and fertilizer (urea) tank mixture on juvenile frog stress levels, acetylcholinesterase (AChE) biomarker analysis, as well as bioaccumulation. Southern leopard frogs (*Lithobates sphenocephala*) were reared from eggs through post-metamorphosis at Washington College, Chestertown, MD. At 30-90 days post-metamorphosis, 96 frogs were placed individually in terrestrial microcosms sprayed with an individual chemical or tank mixture for the duration of an 8-hour exposure. Following exposure, all frogs were transferred to clean, aquatic microcosms for 1-hour to obtain corticosterone samples followed by euthanasia. Brain tissues were obtained from all 96 frogs to evaluate acetylcholinesterase then whole-body tissue homogenates were analysed for bioconcentration. Atrazine had a significant effect in increasing corticosterone stress levels among frogs, particularly when combined with alachlor and urea ($p< 0.01$). Stress levels were highest among frogs in the combined atrazine, alachlor and urea tank mixture treatment. Atrazine increased AChE levels ($p< 0.01$) among exposed frogs while urea decreased AChE ($p=0.01$), although no interactive effects of chemical combinations emerged. Bioconcentration of atrazine in frog tissues was 64% greater in the tank mixture containing all 3 compounds as compared to the individual atrazine treatment and alachlor bioconcentration was 54% greater in the full tank mixture relative to the alachlor treatment alone. Agrochemicals can lead to altered stress and impaired physiological responses in amphibians, and when in combination their effect is not easily predicted. These biological changes may limit reproduction, immune response, predator avoidance and many other critical physiological functions. Although challenging, an improved understanding of the effects of co-exposure to environmental contaminants in amphibians is important for their conservation.

**WP173 Investigating the Effects of Agricultural Land Use on Wood Frog (*Lithobates sylvaticus*) Habitat in the Prairie Pothole Region – Northern Great Plains**

*G. Ruso, University of Saskatchewan; C.A. Morrissey, University of Saskatchewan / Biology; N.S. Hogan, University of Saskatchewan / Department of Animal and Poultry Science and Toxicology Centre; C. Sheedy, AAFC / Trace Residue Analysis and Immunochemistry; T. Jardine, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre*

The wood frog (*Lithobates sylvaticus*) is a wide-ranging species common to the prairie pothole region and may serve as an indicator species for aquatic ecosystem health. Large-scale changes in land use, such as conversion to agriculture, present challenges to amphibians in terms of habitat degradation and pollution as wetlands may act as sinks for contaminants. To investigate the effects of agricultural land use on wood frog habitat we measured various indicators of wetland state, assessed wood frog abundance, and tested water samples for a suite of pesticides from five study areas, two reference and three agriculture-dominated, in central Saskatchewan, Canada in 2017 and 2018. Despite regular application of pesticides, detection frequency was low in all study areas, perhaps owing to below average rainfall. Seventeen of the 24 tested wetlands had pesticides present, but of the 166 pesticides scanned for, only 14 were detected. The most commonly detected pesticides were the herbicides MCPA and 2,4-D, and the neonicotinoids imidacloprid and clothianidin, with higher detection rates in the three agriculture-dominated areas. Surveys for wood frogs found that only 23 of 71 wetlands had positive visual or audible detection, with just 16 containing egg masses or tadpoles. This suggests that wood frogs may not be as prevalent in these geographically-isolated wetlands as was initially thought based on anecdotal evidence, and may serve as an example of uneven distribution of the species across its large range or be the result of variable environmental conditions. To further examine patterns and causes of wood frog rarity, we used eDNA to 1) validate field surveys for wood frog presence and 2) detect the pathogen ranavirus in these wetlands as a potential causal agent. Principal component analysis will be used to assess the influence of all measured variables, including water chemistry, pesticides, habitat, and disease presence data, on wood frog occurrence in this region.

**WP174 The Development of Anuran Prey-Orientation Behaviors as Indicators of Exposure**

*K.r. Scarlett, Baylor University / Environmental Science; P.W. Cusaac, K. Dudley, J.B. Belden, Oklahoma State University / Integrative Biology; C. Pope, Oklahoma State University / Physiological Sciences; S.T. McMurry, Oklahoma State University / Integrative Biology*

Prey capture in toads consists of a stereotypical series of behaviors beginning with orienting toward the prey item ('prey orientation'), followed by pursuit and striking. The goals of this study were to characterize prey-orientation behaviors and develop an assay for use as an indicator of toxicity from toxicant exposure. We first examined whether reinforcement of prey-orientation behaviors influenced habituation in both male and female Great Plains toads (*Anaxyrus cognatus*) with three three-minute trials. Preliminary results suggest that orientations decreased significantly from minute to minute (p=0.0059). Given the decrease in orientations over the three separate trials, an experiment was then designed to determine if reinforcing the orientation behaviors would reduce overall habituation. Average number of orientations decreased by 60% after oxon exposure compared to the controls (51 vs 20; p< 0.0001); however, the decrease was not significant until day 15. Therefore, future testing was limited to 14 days and toads were given reinforcements. Further testing was performed where a consistent number of orientations were established using different time intervals along with the presence or absence of a food reward (51 ± 8/minute). Toads were exposed in a preliminary trial to a vehicle (70% DMSO, n=3) or chlorpyrifos oxon (4 mg/kg in DMSO, n=11) and orientations were assessed daily. A larger experiment (n=53) with multiple treatments (Blank control, DMSO control, 4 ug/g 70% DMSO-CPO, and 40 ug/g 70% DMSO-CPO) was later conducted. The average number of orientations/min decreased by 34% (56 vs 37 for 4ug/g) and 63% (62 vs 23 for 40 ug/g) within the first 24 hours after exposure. There was no significant interaction effect between dose and sex on prey orientations (p=0.3373); however, main effects tests suggested that exposure to chlorpyrifos oxon significantly reduced orientations toward the simulated prey item (p=0.0041). Additional post hoc analyses indicated that the higher exposure (40 ug/g) of CPO caused a greater suppression of orientation behaviors compared to the other treatments. Additional tests were performed in an attempt to further measure motor coordination and activity. Further information will be discussed relative to the usefulness of prey-orientation behaviors as indicators of toxicity following exposure.

**WP175 Effects of Atorvastatin on steroidogenesis in *Xenopus laevis***

*J. Johnson, R.J. Griffitt, University of Southern Mississippi / Coastal Sciences*

Micropollutant pharmaceuticals have become an emerging threat to aquatic ecosystems. Atorvastatin is one of the most widely prescribed drugs for adults aged 18-64. Following ingestion, atorvastatin has a low bioavailability of 14%; the remainder of the drug is excreted as the parent compound. Wastewater treatment plants do not effectively remove atorvastatin during the treatment process; studies of conventional wastewater treatment plants show removal rates of ~50%, with resulting effluent concentrations of 1-2 ug $L^{-1}$ reported. Statin drugs inhibit endogenous production of cholesterol by inhibiting 3-hydroxy-3-methyl-glutaryl-CoA reductase from producing mevalonic acid in the mevalonate pathway. The reduction in circulating cholesterol levels may affect steroidogenesis by reducing the levels of estrogen and testosterone produced in the pathway. Due to the increased sensitivity of amphibians to aquatic toxins, we hypothesize that frogs may be significantly impacted by exposure to environmental statins resulting in a reduction of endogenous synthesis of cholesterol, with potential downstream impacts on steroidogenesis. The central hypothesis of this study is to directly address this issue by using chronic exposure bioassays to assess the potential for atorvastatin to cause overt reproductive and developmental dysfunction at critical life stages of wetland amphibians. *Xenopus laevis*were exposed to both chronic low levels (0.2 ug/L) as well as acute high levels (2.0 ug/L) of atorvastatin. Following exposure, blood plasma was analyzed for cholesterol content as well as testosterone and estrogen levels in males and females, respectively. Additionally, qPCR was performed to provide insight into effects on the steroidogenesis pathway by atorvastatin as well as to determine the effects of atorvastatin in circumstances where blood plasma analysis was not possible due to life stage. Acute studies indicate statistically significant reduction in circulating cholesterol during the first 96 hours post fertilization.

**WP176 A quantitative AOP for activation of the Ah Receptor leading to early life stage mortality in amphibians and reptiles**

*J.A. Doering, USEPA / Mid-Continent Ecology Division; A. Schroeder, University of Minnesota, Crookston / Math, Science and Technology; M. Brinkmann, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre; Z. Currie, University of Saskatchewan / Toxicology Centre; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre*

Differences in sensitivity to chemicals among species and taxa is a major challenge to accurate ecological risk assessments. Most toxicity information is collected from a few model species and little is known about the relationship between the sensitivity of model species compare to non-model species. This is particularly true for amphibians and reptiles. Quantitative adverse outcome pathways (qAOPs) are quantitative, biologically-based models which describe key event relationships that link a molecular initiating event (MIE) to an adverse outcome (AO). qAOPs can serve as a useful tool to determine the relationship between the sensitivity of chemicals with a MIE and an AO among species. Previously, a qAOP had been described for the indirect relationship between activation of the aryl hydrocarbon receptor (AHR) by dioxin-like compounds (DLCs) and early life stage mortality in birds and fishes. Reptiles and amphibians bridge the evolutionary gap between birds and fishes. Therefore, considering the qAOP has shared applicability to evolutionarily divergent birds and fishes, it was hypothesized that it also has applicability to amphibians and reptiles. However, little information was available on AHRs or sensitivity to DLCs in amphibians and no information was available for reptiles. Therefore, this study investigated sensitivities to activation of AHRs (AHR1s and AHR2s) in an in vitro AHR transactivation assay and in vivo early life stage sensitivities for an amphibian, the African clawed frog (*Xenopus laevis)*, and a reptile, the common snapping turtle (*Chelydra serpentina*). Early life stage mortality was assessed in African clawed frog embryos exposed to serial concentrations of one of two DLCs: 2,3,7,8-TCDF or 2,3,4,7,8-PeCDF. Early life stage mortality was assessed in common snapping turtle embryos exposed to serial concentrations of one of four DLCs: 2,3,7,8-TCDF, 2,3,4,7,8-PeCDF, PCB 126, or 2,3,7,8-TCDD. Further, in vitro AHR transactivation assays were used to determine sensitivity to activation of AHR1 alpha and beta isoforms of African clawed frog and AHR1 and AHR2 of common snapping turtle to the selected DLCs. Validating the qAOP linking activation of the AHR to early life stage mortality in birds and fishes for applicability to amphibians and reptiles could guide more objective ecological risk assessments of DLCs to native species of amphibians and reptiles, which are not easily studied.

**WP177 In vitro toxicity of Perfluorooctanic Acid, Benzo[a]pyrene, and Polychlorinated Biphenyl 77 in Loggerhead Sea Turtle Skin Fibroblasts**

*J.D. Pierro, Texas Tech University / TIEHH / Environmental Toxicology; C. Wittmaack, Texas Tech University / Department of Environmental Toxicology; J.G. Surles, Texas Tech University / Department of Mathematics and Statistics; B.M. Higgins, NOAA National Marine Fisheries Service; C.A. Godard-Codding, Texas Tech University / TIEHH / Department of Environmental Toxicology*

Perfluorooctanic Acid (PFOA), Benzo[a]pyrene (B[a]P), and Polychlorinated Biphenyl 77 (PCB 77) are contaminants commonly found in marine environments. These chemicals have been detected in the tissues, eggs, and prey items of sea turtles, including in loggerheads (*Caretta caretta*). These chemicals are known for cytotoxicity, mutagenicity, carcinogenicity, immunotoxicity, adverse reproductive and developmental effects, and negative impacts on pulmonary, renal and hepatic systems in a wide range of species. Their effects in the threatened loggerhead and in other sea turtle species are poorly known since in vivo toxicological testing is prohibited in these animals. Here we report on in vitro cytotoxicity of PFOA, B[a]P, and PCB 77 in primary loggerhead skin cells. We established the primary cultures from skin biopsies collected from healthy animals reared at the NOAA Sea Turtle Facility in Galveston, Texas. The effects of chemical exposure were measured by two common viability assays – MTT and Lactate Dehydrogenase (LDH). Primary cultures (n=7) were exposed to each chemical for 24, 48, 72, and 96 hours. Exposure concentrations were based upon environmentally relevant levels found in sea turtle eggs, plasma, tissue, prey items, and habitats. Toxicant concentrations were 0.01, 0.1, 1, and 10 µM for PCB 77 and B[a]P, and 0.05, 0.5, 5, 50, and 500 µM for PFOA. Data was analyzed using Analysis of Variance (ANOVA) and Tukey's tests, and Kruskal-Wallis and Wilcoxon tests where applicable. Preliminary analyses detected toxicity of PFOA, B[a]P, and PCB 77 at several time points and concentrations. Cytotoxicity was detected by MTT assays at the highest doses following 72 and 96 hours of exposure for PCB 77 and PFOA. Additional MTT and LDH data analyses are underway. To our knowledge, this is the most comprehensive in vitro study to date on organic contaminant toxicity in sea turtle primary cultures obtained from healthy animals. We are currently developing mathematical models to extrapolate these in vitro data across biological organization levels in order to provide novel information applicable to risk assessment techniques on populations of sea turtles.

**WP178 CYP1A induction in Loggerhead (*Caretta caretta*) sea turtle organotypic skin cultures exposed to benzo[a]pyrene and PCB 126**

*C.S. Calvin, Texas Tech University / TIEHH / Environmental Toxicology; B.M. Higgins, NOAA National Marine Fisheries Service; C.A. Godard, Texas Tech University / Environmental Toxicology / The Institute of Environmental and Human Health*

Organotypic culture refers to the culture of thin precision-cut slices of tissue. Several studies have indicated that this *ex vivo* methodology more closely represents in vivo systems than the traditional in vitro cultures that lack a three-dimensional structure and are composed of only one cell type. Organotypic culture is widely used for toxicity testing in pharmacology and medicine but is still novel in wildlife. We previously validated the viability of organotypic skin cultures in the loggerhead sea turtle, both in media with and without fetal bovine serum, for up to 96h. Viability was assessed by three different endpoints: (1) lactate dehydrogenase (LDH) measured in the culture media via a commercially available LDH Assay kit, (2) quantitation of the internal potassium in skin slices by flame atomic absorption spectrometer, and (3) cell culture establishment from skin slice. The six sea turtle species that inhabit the coastal waters of the United States are labeled as either vulnerable, endangered, or critically endangered by the International Union Conservation of Nature Red List. Polycyclic aromatic hydrocarbons (PAHs) and halogenated aromatic hydrocarbons are common marine contaminants and have been detected in sea turtle tissues. Little is known about the potential adverse effects of these chemicals in sea turtles. Organotypic cultures were established from skin biopsies collected from healthy animals reared at the NOAA Sea Turtle Facility in Galveston, Texas. Tissue slices were cultured in media dosed with benzo[a]pyrene (B[a]P) for 4, 24, 48, and 72h, or with polychlorinated biphenyl 126 (PCB 126) for 24 and 72h. The enzymatic activity of CYP1A, a well-established biomarker of exposure for PAHs and planar halogenated aromatic hydrocarbons, was measured using ethoxyresorufin O-deethylase (EROD), methoxyresorufin O-demethylase (MROD), benzyloxyresorufin O-debenzylase (BROD), and pentoxyresorufin O-depentylase (PROD) by spectrophotometry. Preliminary results indicated that CYP1A detection could be detected in the skin organotypic cultures after exposure to B[a]P. Further analyses for both B[a]P and PCB 126 exposure scenarios are underway.

**WP179 Monoclonal antibodies against loggerhead sea turtle IgY isoforms reveal differential contributions to antibody titers & relatedness with other turtles**

*M.L. Rodgers, The University of Southern Mississippi / Division of Coastal Sciences; C.D. Rice, Clemson University / Biological Sciences*

Serum collected from loggerhead sea turtles, *Caretta caretta*, in the southeast Atlantic Ocean was used to purify immunoglobulin Y (IgY) and develop IgY isoform-specific monoclonal antibodies (mAb). Typical IgY has two heavy and two light chains with a total molecular weight of ~180 kDa. Another common isoform of IgY exists as a truncated form of ~120 kDa, known as IgY (ΔFc). Reptiles and birds may produce the 180 kDa IgY isoform, the 120 kDa IgY (ΔFc) isoform (Fab), or both. mAb LH12 was developed against the 66 kDa heavy chain of IgY, mAb LH1 was developed against the truncated heavy chain of approximately 37 kDA, and mAb LH9 was developed against the 23 kDa light chains. mAb LH9 reacted with the light chains of all sea turtles, mAb LH12 reacted with the long heavy chain of all sea turtles within the family Cheloniidae, and mAb LH1 reacted with the truncated form of IgY in both olive and Kemp's ridley turtles. Circulating IgY antibody titers against *M. mycobacterium*, *E. coli*, and *V. parahaemolyticus* were determined by ELISA in 16 loggerhead samples using these mAbs. mAb LH12 detected higher titers than mAb LH1, and mAb LH9 detected the highest titers due to light chains being shared by both IgY isotypes. Going forward, these new additions to the limited tool box of sea turtle-specific reagents are now available to the scientific community examining the health of these animals in their natural habitat, as well as animals in recovery centers and aquariums.

**WP180 Effects of Exposure Area and Dose on Uptake of Hydrophobic Environmental Contaminants by Acris blanchardi via Dry Patch System (DPS) Exposure Method**

*W.H. Mimbs, Oklahoma State University / Zoology; S.T. McMurry, J.B. Belden, Oklahoma State University / Integrative Biology*

Exposure of terrestrial amphibians to environmental contaminants is thought to occur primarily via the dermal route of exposure as opposed to the oral route primarily considered in mammalian and avian species. In order to better characterize this route of exposure and how different skin areas on the amphibian affect uptake, a "dry" dermal patch application method was developed by the authors that removes several potentially confounding factors such as soil properties and amphibian-soil contact time and allows consistent dosing of test substances to different parts of the amphibians. In this study, we sought to examine the differences in peak concentration and time to peak concentration of the contaminants based on the size of the exposure patch used. Five compounds dissolved in acetone were applied (1,200 ng of each compound) to polytetrafluoroethylene (Teflon™) strips measuring either 12 $mm^2$ or 25 $mm^2$ by area and the patch allowed to dry. These strips were then applied to adult *Acris blanchardi* (Blanchard's cricket frog) on either the dorsal or ventral side, and secured using water-proof adhesive bandage material and tissue adhesive. Five individuals were sampled from the dosed population at 0, 0.5, 1, and 3 hours after exposed began, euthanized, their tissue extracted using the QuEChERS method, and the resulting extract analyzed via GC/

MS. Further, a second test using the same test procedures was performed with the 25 $mm^2$ size strips dosed with the five contaminants at either 24 or 48 ng/$mm^2$.

**WP181 Differences in Hydrophobic Contaminant Uptake Between an Aquatic and a Terrestrial Species via Dry Patch System (DPS) Exposure Method**

*W.H. Mimbs, Oklahoma State University / Zoology; S.T. McMurry, J.B. Belden, Oklahoma State University / Integrative Biology*

Exposure of terrestrial amphibians to environmental contaminants is thought to occur primarily via the dermal route of exposure as opposed to the oral route primarily considered in mammalian and avian species. To better characterize this route of exposure and how different skin areas on the amphibian affect uptake, a "dry" dermal patch application method was developed by the authors that removes several potentially confounding factors such as soil properties and amphibian-soil contact time and allows consistent dosing of test substances to different parts of the amphibians. In this study, we sought to examine the differences in uptake of five hydrophobic contaminants exposed to the aquatic *Xenopus laevis* and the terrestrial *Acris blanchardi* based upon the species and whether the patch was applied dorsally or ventrally. Five compounds dissolved in acetone were applied to polytetrafluoroethylene (Teflon™) strips measuring 25 $mm^2$ by area at a rate of approximately 48 ng chemical/$mm^2$ and the patch allowed to dry. These strips were then applied to both individuals of species (Blanchard's cricket frog) on either the dorsal or ventral side and secured using water-proof adhesive bandage material and tissue adhesive. Five individuals were sampled from the dosed population at 0, 0.5, 1, and 3 hours after exposed began, euthanized, their tissue extracted using the QuEChERS method, and the resulting extract analyzed via GC/MS.

## Remediation and Restoration: Assessing and Measuring Effectiveness for Contaminated Sediments

**WP182 Colonization and growth of organohalide respiring biofilms on carbonaceous amendments**

*S. Capozzi, University of Maryland at College Park / Environmental Science; B.V. Kjellerup, University of Maryland at College Park / Civil and Environmental Engineering*

Removal of polychlorinated biphenyls (PCBs) from contaminated aquatic sediments is a priority due to the ability of these persistent organic pollutants to enter the food chain, where they bioaccumulate with toxic and carcinogenic causes as a result. Recent success with reduction of the bioavailability of PCBs due to adsorption onto carbonaceous amendments has led to the recognition of in situ treatment as a viable remediation approach for contaminated sediment. *In situ* microbial degradation of PCBs represents a significant improvement in recent remediation efforts, since previous attempts have largely been unsuccessful due to the low abundance of naturally occurring PCB-degrading microorganisms as well as the use of liquid inoculum for bioaugmentation where free floating microorganisms are easily washed away. To overcome these challenges, this study evaluated the potential for localizing and concentrating PCB-dehalorespiring biofilms onto surfaces of materials varying in material properties (i.e. sorption, conductivity, surface area) and applied these biofilm communities to microcosms amended with Grasse River sediment. Biofilm colonization and growth of *Dehalobium chlorocoercia* DF-1 on coal activated carbon (AC), bone biochar (BC), polyoxymethylene (POM), and sand was monitored over 159-day period. DF1 formed thin and patchy biofilms ranging in thickness from 3.9 to 6.7 µm and the surface area covered with biofilm (i.e. biosurface area) varied for the tested materials. Biosurface area increased steadily over 159 days and showed that highest coverage for coal AC (20.2 ± 4.1%) followed by bone BC (14.7 ± 5.8%), POM (10.2 ± 2.5%) and sand (5.5 ± 1.4%). The biosurface area increased with increasing sorptive capacity thus indicating a preferential attachment on more sorptive materials. In addition, quantitative polymerase chain reaction (q-PCR) results showed a high abundance of DF1 on the various materials after 159 days with bacterial numbers of $6.12x10^9$, $1.53x10^{10}$,$1.17x10^9$, and $3.46x10^9$ gene copies per gram d.w. of coal AC, bone BC, POM and sand, respectively. Thus it was possible to establish organohalide respiring biofilms attached to sorptive materials at high cell densities that dechlorinated PCBs during the experiment. Future work will include assessment of the biofilm inoculum for bioremediation of weathered PCB and if organohalide respiring bacteria embedded within a biofilm can successfully be applied to subsurface environments.

**WP183 Comparative potentials of *Duranta repens* and *Duranta erecta* in nickel and asenic remediation**

*N.J. Akpan, O.T. Aladesanmi, Obafemi Awolowo University / Institute of Ecology and Environmental studies*

This study assessed the bioremediation potential of two ornamental plants (*Duranta repens and Duranta erecta)* exposed to gradient concentrations of arsenic and nickel. Metal solutions of $As_2O_3$ and $NiCl_2.6H_2O$ at the concentrations of 0, 10, 20, 40, 80 and 160 mg/kg were prepared using analytical grade salts. Data collected at the end of eight weeks after planting (WAP) were analysed using descriptive and inferential statistics. The physical and chemical parameter of experimental soil prior to planting were within the acceptable limit. At 8 WAP, the soil pH values decreased from 6.2 to 5.7 while available phosphorus increased from 34 to 44 mg $Kg^{-1}$ with increase in concentration of arsenic. On the other hand, for nickel, the soil pH increased from 6.6 to 7.1 while organic contents showed a steady increase from 2.9 to 4.8 g $kg^{-1}$ with increase in concentration of nickel. Both *Duranta repens and Duranta erecta* survived across all concentration of both metals in the first two weeks after planting, though *Duranta erecta* experienced faster growth than *Duranta repens.* The growth rate of the two plants began to decline after three weeks after planting at higher concentrations of nickel and eventually led to the death of *Duranta erecta* at 160 mg/kg and *Duranta repens at* 80 mg/kg treatments. For *Duranta repens,* arsenic toxicity was observed in term of retarded growth from 40 mg/kg to 160 mg/kg which led to the death of the plant at 160 mg/kg while *Duranta erecta* survived across all concentrations of arsenic. *Duranta erecta* had a higher root length than *Duranta repens* which was 156.7% and 150% at 20 mg/kg for arsenic as well as 167.4% and 134% for nickel. *Duranta erecta* showed poor bioconcentration factor for arsenic which ranged between 0.85 and 1.2 but showed a good bioconcentration factor for nickel which ranged between 2.2 to 4.7. *Duranta repens* had bioconcetration factor for both arsenic and nickel ranged between 1.1 to 1.4 and 3.6 to 8.0 respectively. *Duranta repens* had transfer factor for both arsenic and nickel while *Duranta erecta* only had transfer factor for nickel. It was concluded that both plants are suitable for phytoremediation of heavy metals. While *Duranta repens* is suitable for phytoextraction of both arsenic and nickel, *Duranta erecta,* is suitable for phytoextraction of nickel but phytostabilizaon of arsenic.

**WP184 Natural amorphous organic matter does not diminish the bioavailability of 2,3,7,8-tetrachlorodibenzo-p-dioxin to mice**

*Q. Yuan, Michigan State University / Plant, Soil and Microbial Sciences; B. Sallach, Environment Department University of York; R. Crawford, Michigan State University / Institute for Integrative Toxicology; H. Li, Michigan State University / Plant, Soil and Microbial Sciences; C. Johnston, Purdue University / Crop, Soil, and Environmental Science; B. Teppen, Michigan State University / Plant, Soil and Microbial Sciences; N. Kaminski, Michigan State University / Institute for Integrative Toxicology; S. Boyd, Michigan State University / Department of Plant, Soil and Microbial Sciences*

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is one of the most persistent organic pollutants (POPs) found in soils and sediments. It has been linked to several adverse health outcomes in humans and wildlife, including suppression of the immune system. This contaminant is readily sorbed to soils/sediments due to its extremely low water solubility. Presently, the bioavailability of soil/sediment-associated TCDD to mammals is not completely understood. As demonstrated in our previous studies, TCDD adsorbed to inorganic constituents representing natural geosorbents, i.e. porous silica and smectite clay, exhibited the same bioavailability as TCDD dissolved in corn oil. In contrast, when sequestered by activated carbon TCDD bioavailability to mice was completely eliminated. In this study, we evaluated the effects of natural amorphous organic matter (NOM), in the form of an aquatic humid acid, on the bioavailability of TCDD using the same mammalian (mouse) model. The TCDD (dissolved in DMSO) was mixed with an aqueous suspension of the NOM and with corn oil separately, then administered to mice via oral gavage. Based on its very low water solubility most TCDD is expected to be associated with NOM, most likely by partitioning into a hydrophobic microenvironment within the three dimensional structure of the NOM. The relative bioavailability of TCDD was assessed by quantifying and comparing two sensitive aryl hydrocarbon receptor-mediated responses in mice: 1) hepatic induction of *cyp1A1*mRNA, and 2) suppression of immunoglobulin M (IgM) antibody-forming cell (AFC) response which is an indicator of immunotoxicity. Similar hepatic induction of cyp1A1 mRNA and suppression of IgM AFC was observed for TCDD in the NOM-sorbed form and dissolved in corn oil, revealing no loss of bioavailability due to its association with NOM. Hence, NOM-sorbed TCDD is as capable of suppressing humoral immunity in mice as TCDD dissolved in corn oil, i.e TCDD exhibits 100% relative bioavailability when associated with amorphous NOM. These results indicate that NOM-sorbed TCDD is likely to fully retain its bioavailability to mammals and, by inference, humans.

## High-Throughput Screening and Ecological Risk Assessment

**WP185 Adaptation of methods for the immunofluorescent visualization of thyroxine (T4) in larval fathead minnows (*Pimephales promelas*)**

*L. Thornton, University of North Texas / Biology; B.J. Venables, University of North Texas / Advanced Environmental Research Institute; M.K. Sellin Jeffries, Texas Christian University / Department of Biology*

Thyroid disruption screening methods in larval fish often include the assessment of growth and thyroid-related gene expression. The direct measurement of thyroid hormones (THs) has also been employed via enzyme linked immunosorbent assays (ELISAs) and liquid chromatography mass spectrometry (LCMS). However, ELISAs often require a large number of animals to be sacrificed and the pooling of tissues to achieve detectable levels of THs whereas the utilization of LCMS calls for expertise in analytical chemistry techniques. In contrast, the thyroxine-immunofluorescence quantitative disruption test (TIQDT), which allows for the fluorescent labeling of thyroxine (T4) within thyroid follicles, requires minimal training, reduces animal use, consumes only low-cost reagents and produces relatively rapid results. As such, the goal of the current study was to adapt the TIQDT for use in the fathead minnow (*Pimephales promelas*), a commonly used fish model for aquatic toxicity testing including thyroid disruption. Fathead minnow larvae were exposed to either a low (25 mg/L) or high dose (70 mg/L) of the model thyroid suppressant, propylthiouracil (PTU), for 30 days beginning at < 24 hours post hatch. At 7 days post hatch (dph), a subset of larvae was sacrificed for the immunofluorescent labeling of T4. Each larva was imaged and integrated density (ID, a metric that accounts for pixel intensity and area) was measured. Relative to control larvae, 4.8 and 4.5-fold decreases in ID were observed amongst low and high dose PTU exposed larvae, respectively. In addition, significant reductions in growth were observed at 7 and 30 dph, and alterations in thyroid-related gene expression (*i.e. deiodinase 2 (di2)* and *transthyretin* (*ttr*)) were observed at 30 dph, further confirming the inhibition of T4 synthesis. The results of this study demonstrate that the TIQDT is a viable method for the assessment of T4 in larval fathead minnows and may be applicable in the screening of potential thyroid-disrupting compounds.

**WP186 High Throughput Screening and Environmental Risk Assessment State of the Science and Emerging Applications**

*N. Vinas, US Army / Engineer Research and Development Center; D.L. Villeneuve, USEPA / National Health and Environmental Effects Research Laboratory*

In 2007, the US National Research Council (NRC) published a report that clearly identified the lack of toxicity data for most existing chemicals as a major barrier to efficient and cost-effective risk assessment. The authors proposed a path forward that emphasized the use of predictive, high throughput assays to characterize the ability of chemicals to perturb biological pathways critical to health. The scientific community rapidly embraced this vision and major efforts such as the US Environmental Protection Agency ToxCast program were developed to advance the field. While the vision was directed towards human health risk assessment, it was soon understood that it could also be translated to ecological risk assessment. On April 2018 SETAC held a focused topic meeting to evaluate the state of the science with regard to High-Throughput Screening and its emerging applications to environmental risk assessment. Over 100 international participants from academia, government, industry, and other sectors contributed to presentations, demonstrations, and discussions centered on the topic. The meeting provided an opportunity to explore the progress that has been made, as well as the challenges that remain with regard to implementation of the NRC's vision and broadening its scope to encompass a full range of environmental risk assessment contexts. Here, we highlight some of the major topics and discussions from the focused topic meeting with specific regard to major needs for implementation that were also identified by the NRC in 2007, as well as challenges, opportunities, and next steps.

**WP187 In Vitro Screening for Chemical Inhibitors of Human and Amphibian Iodotyrosine Deiodinase Activity**

*J.H. Olker, J.J. Korte, USEPA / ORD / NHEERL / Mid-Continent Ecology Division; P.C. Hartig, M.C. Cardon, USEPA / ORD / NHEERL, Toxicity Assessment Division; M.W. Hornung, S.J. Degitz, USEPA / ORD / NHEERL / Mid-Continent Ecology Division*

Iodotyrosine deiodinase (dehalogenase, IYD) catalyzes iodide recycling from monoiodotyrosine (MIT) and diiodotyrosine (DIT) and promotes retention of iodide in thyroid follicular cells. IYD has an important role in maintaining appropriate levels of thyroid hormones through conservation of this scarce micronutrient and is especially critical for organisms in low iodide environments, including most freshwater ecosystems. Loss of function or chemical inhibition of IYD reduces thyroid hormone synthesis, which leads to insufficiency in tissues and subsequent negative developmental consequences. Our objective was to develop a 96-well plate in vitro assay that could be used to screen chemicals for inhibition of IYD and to compare inhibition between mammals and amphibians. We utilized recombinant human IYD enzyme and *Xenopus laevis* liver microsomal fractions to establish robust assays using MIT as the substrate, 3-nitro-L-tyrosine (MNT) as the positive control, and a non-radioactive detection method. A set of ten chemicals was used to establish the assay, including seven known or suspected inhibitors of IYD (MNT, 3,5-dinitrotyrosine, 3,5-dibromotyrosine, triclosan, phloxine-B, L-mimosine, and bromoxynil) and three suspected non-inhibitors (genistein, dibutyl phthalate, and bisphenol A). Chemicals were tested at a maximum concentration of 200 µM, with seven graded concentrations to produce an inhibition concentration-response curve. Assay performance metrics support use of this assay for screening, with high Z' factor (0.7 or greater) and low variability in the control chemicals (DMSO and MNT). With the recombinant human IYD, five chemicals produced inhibition of IYD ranging from 60-100% (compared to DMSO control), with IC50 ranging from 0.05 µM to >200 µM. There was strong cross-species agreement between human and *Xenopus*, and all chemicals produced comparable maximum inhibition and IC50s, with minor shifts in rank order potency. These assays for inhibition of IYD activity in a 96-well plate format can be used for future screening of large chemical libraries. Additionally, these results indicate that IYD response to potential chemical inhibitors is conserved across vertebrates. *This abstract does not necessarily reflect USEPA policy.*

**WP188 In Vitro Screening of *Xenopus laevis* Deiodinase 3 for Inhibition by ToxCast Chemicals**

*S.A. Mayasich, Oak Ridge Institute for Science & Education at USEPA / NHEERL / Mid-Continent Ecology Division; J.S. Denny, USEPA / Mid-Continent Ecology Division; J.J. Korte, S.J. Degitz, M.W. Hornung, USEPA / ORD / NHEERL / Mid-Continent Ecology Division*

Thyroid hormones are necessary for normal sequential development and metamorphosis of amphibian tissues and organs. Deiodinase enzymes in peripheral tissues are critical components of the system that catalyze the removal of an iodine from thyroid hormones to either activate or inactivate the hormone. We conducted a screening study of chemical inhibitory activity toward amphibian (*Xenopus laevis*) Type 3 iodothyronine deiodinase (DIO 3) enzyme. The chemicals were selected from across the ToxCast Phase 1, Phase 2 and e1k chemical libraries, based on results from previously screening these chemicals against the human DIO 3. Recombinant *X. laevis* DIO 3 enzyme was produced in cell culture and used in a 96-well plate in an initial single-concentration (200 µM) screening assay. Chemicals were further selected for testing in concentration-response mode if found to inhibit the *X. laevis* DIO 3 in the single-concentration screening, as well as having low IC50 values for the human DIO 3 enzyme. Some of these chemicals of interest included antimicrobials Triclosan and chlorhexidine diacetate, and the insecticide Fipronil. Xanthohumol was used as a positive control for DIO3 inhibition. The IC50 values for the human DIO 3 enzyme for these four example chemicals were 61.1, 2.6, 1.2 and 0.3 µM, respectively. The IC50 values for *X. laevis* DIO 3 were 266.3, 9.5, 0.7 and 0.3 µM, respectively. Overall, the data indicate similar activity of the chemicals, likely due to conserved amino acids between these species within the enzymes' catalytic sites. *This abstract does not necessarily reflect USEPA policy.*

**WP189 Incorporating HTS data in classical data based screening risk assessments**

*H. Plugge, P. Raya, Verisk 3E*

High Throughput Screening (HTS) data has many applications but such applications to date have mostly focused on molecular toxicology such as Adverse Outcome Pathways (AOPs). Until such time when AOPs are truly curated in detail and ubiquitous is there a way to use HTS data to perform risk assessments? Various methods have been proposed but one of the common drawbacks is the complexity and sheer size of a database such as ToxCast21. In depth familiarity with the various enzyme assays (all 1,000 plus) is required to make a determination of possible mechanistic relations. At greater than 1 billion data points (approximately 10,000 chemicals by 1000 assays by on average > 100 datapoints per assay) when fully populated, ToxCast21 both deserves in depth examination as well as the ability to survey big trends in big data. Verisk 3E decided to provide a simplified recast of ToxCast21 data which is more amenable to interpretation by classical toxicologist and would accelerate the adoption/use of such data within the regulatory community. Rather than displaying test results by assay type first (i.e. lump all stress response type assays together) we first sort by tissue type (e.g. liver). This allows correlation of classical target organ information with HTS data without getting stuck on what a response/hit on XYZ assay really means/implies. Sorting by tissue type truly provides a big picture of big data. High frequency of "hits" for a particular tissue correlates fairly well with target organ information, although additional targets often pop up. Drilling down within tissue types allows one to focus on families of assays e.g. DNA binding. We used Aldrin as an example. Liver hits totaled 36 out of 220 liver tissue assays. Cell cycle, nuclear receptor and DNA binding had the highest hit ratio. Cytokines and cell morphology had relatively low response rates. Other tissue systems with high hit ratios include cervix, skin and vascular. For the latter (not surprisingly) cytokine related assays had the highest hit ratio/response rate. Based on the number of tissues and assay type we developed a risk assessment frame work, which allows numerical scoring of an HTS risk screening estimate. The methodology allows incorporation of HTS data within a classical toxicology based risk assessment screening framework. HTS data can now be used for regulatory screening using the established 3E Green Score methodology.

**WP190 Salmonid pituitary cells as a test system for screening endocrine disrupting compounds**

*L. Harding, University of Washington / Aquatic and Fishery Sciences; I.R. Schultz, NOAA / Northwest Fisheries Science Center; G. Young, University of Washington / School of Aquatic and Fishery Sciences; P. Swanson, NOAA Fisheries / Northwest Fisheries Science Center*

The pituitary gland is a central regulator of reproduction, producing two gonadotropins, follicle-stimulating hormone (FSH) and luteinizing hormone (LH), which regulate gonadal development, sex steroid synthesis and gamete maturation. We have previously observed that waterborne exposure of salmon and trout to 17α-ethynylestradiol (EE2) and the selective serotonin reuptake inhibitor (SSRI) fluoxetine alter LH beta subunit (*lhb*) and FSH beta subunit (*fshb*) mRNA levels, respectively, in vivo. These results motivated us to expand our studies by developing an in vitro test system using pituitary cells isolated from previtellogenic female coho salmon and rainbow trout. Preliminary studies were performed to optimize culture conditions and to establish the time course of *fshb* and *lhb* gene expression with and without addition of endogenous sex steroids (estrogen [E2] or 11-ketotestosterone). After optimizing assay conditions, a suite of 12 contaminants and other hormones was evaluated for their effects on *fshb* and *lhb* gene expression. Each chemical was tested at 4-5 different concentrations up to solubility limitations in cell culture media. Results indicated more chemicals altered *lhb* than *fshb* mRNA levels. The more potent chemicals were estrogens (E2, EE2) and aromatizable androgens (testosterone), which induced *lhb*. The estrogen receptor antagonist 4-OH-tamoxifen decreased the E2 stimulated expression of *lhb*. Among several SSRIs tested, the sertraline metabolite norsertraline was notable for both increasing *fshb* mRNA levels and decreasing the E2 stimulation of *lhb*. These results indicate that diverse types of chemicals can alter gonadotropin production in fish. Further, we have shown that pituitary cell culture is useful for screening chemicals with potential endocrine disrupting activity and can support quantitative adverse outcome pathway testing. Supported by EPA-STAR grant R835167.

**WP191 ToxCast Results to Identify Chemical Hazards Across Species**

*C. LaLone, USEPA / Mid-Continent Ecology Division; D.L. Villeneuve, USEPA / National Health and Environmental Effects Research Laboratory; J.A. Doering, USEPA / Mid-Continent Ecology Division; B.R. Blackwell, USEPA ORD / National Health and Environmental Effects Research Laboratory; J. Swintek, Badger Technical Services; G.T. Ankley, USEPA / National Health and Environmental Effects Research Laboratory*

The US Environmental Protection Agency's (EPA) Toxicity Forecaster (ToxCast™), is a suite of rapid high-throughput screening (HTS) assays used to evaluate chemical safety. Thousands of chemicals have been screened in these HTS assays that cover broad biological space. However, the assays utilized in ToxCast are primarily mammalian-based assays (e.g., human, rat, mouse) as the original intent was to utilize the results to prioritize chemicals based on potential impacts to human health. Recognizing the wealth of information that is available through ToxCast screening results, it is important to consider the utility of these data in understanding chemical effects across species. Therefore, to expand the utility of these data the USEPA's Sequence Alignment to Predict Across Species Susceptibility (SeqAPASS; https://seqapass.epa.gov/seqapass/) tool was employed to evaluate how well the protein targets represented in the ToxCast Assays are conserved across species. For extrapolation of ToxCast results the SeqAPASS tool evaluates protein similarity between protein sequence from the model organism used in the HTS assay and all species with sequence information available, making a prediction of which species are likely similar enough to have the protein target available for a chemical to act upon. This initial understanding of whether the chemical target is available in other species can provide the foundation for extrapolating ToxCast results across species and further identifying where extrapolation is not practical. All 484 ToxCast assays associated with a protein sequence were evaluated with SeqAPASS and made publicly available both through ToxCast and the USEPA's CompTox Chemistry Dashboard (https://comptox.epa.gov/dashboard). Four case studies were developed to describe the SeqAPASS results for ToxCast assay target families including *G-protein-coupled receptors,DNA-binding proteins*, *esterases*, and *growth factors*. These SeqAPASS case studies demonstrate how broadly the HTS assay results can be extrapolated beyond the model organism to understand potential chemical hazard. *The contents of this abstract neither constitute nor reflect official USEPA policy.*

**WP192 What needs to be true: Thoughts on incorporating high-throughput screening data in environmental risk assessments**

*E.M. Mihaich, ER2; K.A. Connors, The Procter & Gamble Company / Environmental Stewardship and Sustainability Organization; K.K. Coady, The Dow Chemical Company / Toxicology Environmental Research and Consulting*

The Environmental Risk Assessment (ERA) framework provides a systematic approach to evaluate the risk of exposure to contaminants in the environment. While the overall framework is generally conserved, ERA practices can differ between countries and regions, as these decisions are based on science but implemented as policy. Some differences include: accepted test species, required testing approaches/guidelines, and the magnitude of applied assessment factors. Differences aside, the quality of the risk assessment is dependent on the availability of data and models for estimating exposure and identifying adverse effects. High throughput (HTP) assays have the potential to not only increase the amount of data available for assessments while reducing the cost and time of generating the data, but also to help develop better predictive models of responses to contaminants. High throughput screening data are globally accessible for thousands of chemicals and models are being developed to help predict potential exposure and effects based on chemical structure and property information. There are, however, a number of challenges to a broad regulatory acceptance for the use of HTP data in ERA. For example, an accessible HTP testing infrastructure is needed in order to support the development and wider use of these new technologies. In addition, HTP data and models have been largely focused on vertebrates/mammals and to date there has not been much focus on identifying pathways and endpoints important in ERA (e.g., algae and invertebrates). Several ways that HTP data could be incorporated into an ERA will be discussed, including: 1) use in compound development, 2) identifying potential modes of action, 3) directly replacing a required toxicity endpoint, 4) refining applied assessment factors, and 5) building and supporting chemical category extrapolation. Several key caveats will be explored and case studies will be used to illustrate challenges and successes in the use of HTP in ERA.

## Developments in Water Quality Monitoring and Analytical Methods in Support of Water Reuse

**WP193 Ion exchange resins and functionalized nanofibres: A comparative study for the treatment of brine**

*E. Omoniyi, University of the Western Cape South Africa / Chemistry*

Mining, metal extraction, electroplating and desalination processes may result in the release of effluents containing heavy metals and other contaminants into the environment. Desalination processes have resulted in the release of concentrated brine reject, and this poses a threat to the fresh water systems and the environment. Complex brine mixture disposed into the evaporation ponds and other environmental media may experience slow rate of evaporation, due to the presence of the cations such as $Ca^{2+}$ and $Mg^{2+}$. It is therefore imperative to remove these ions to enhance the evaporation rate of the brine mixture. Various methods of heavy metals removal from aqueous solutions such as ion exchange, adsorption, electrochemical treatment, etc. were evaluated. Amongst these, adsorption, a method which depends solely on the functional group(s) on the adsorbent surfaces was investigated. The application of functionalized super hydrophilic materials such as nanofibres as adsorbents to brine treatment, alongside chelating resins in a comparative study of batch adsorption experiment showed interesting characteristics. The surface functionality and morphology/pore structure is characterized using FT-IR and scanning electron microscopy (SEM) respectively, while metal ion concentration determined using the ICP-OES. The adsorption kinetics of the resin and the nanofibre in the adsorption will be studied to assess the performance of nanofibre compared to a conventional commercial resin. The kinetics of the nanofibre-cation interaction is however expected to be sufficiently rapid, reaching equilibrium faster when compared to the chelating resin. The faster kinetics can be attributed to the nanofibre's characteristics such as high porosity, large surface area per unit mass and small interfibrous pore size of the polymer material.

**WP194 Fullerenes in aqueous matrices: An experimental design for analytical method development and validation applying spe followed by LC-MS/MS analysis**

*L.R. Diniz, Universidade de Sao Paulo / Bioquimica; L.T. Capellini, Universidade Federal de São Paulo UNIFESP / Departamento de Química; A.d. Fornzari, Pontificia Universidad Catolica de Chile / Facultade Química; E.M. Vieira, Sao Paulo University / Departamento de Quimica e Fisica Molecular; P. Colepicolo Neto, São Paulo University (IQ/USP) / Chemistry Institute; C. Alves-Lima, São Paulo University (IQ/USP)*

The fate and effects of emerging contaminants have attracted the attention of the scientific community in the last years, since these compounds have the propensity to cause adverse consequences, even in low concentrations, to the exposed organisms. Endocrine disrupters (EDs), pharmaceuticals, personal care products, flame retardants, surfactants and metabolites, industrial additives, hormones, gasoline additives, pesticides and nanomaterials (NMs) are examples of this class of substances. Nanomaterials (NMs) or nanoparticles (NPs) are present in many consumer products. The massive production and application of NMs justify its presence in several environments. Fullerenes $C_{60}$ and $C_{70}$ are allotropic forms of carbono produced in highly energetic processes of natural origin or anthropogenic sources. In the last years, the increasing application of nanomaterials in several areas of human endeavor besides their physical and chemical properties, contribute for the growth of the global economy. However, the growing production and application of nanomaterials is also promoting discussions about the possible risks of these compounds to the environment and human health. Data have already been reported on the occurrence of fullerenes in different matrices, including the atmosphere, soils and sediments, and fresh water. This study proposes the development, validation of an analytical method for the extraction, pre-concentration and determination of fullerenes in aqueous matrices with the combination chemometrics methods of experimental design for establishing for better analytical parameters of analysis. A complete factorial design was established to optimize the main experimental parameters that affecting the Solid Phase Extraction (SPE) and used in order at achieve a maximum recovery percentage, followed by liquid chromatography – mass Spectrometry (LC/MSMS) efficiency. Preliminary results were the establishment and validation of the analytical conditions for quantification of fullerene in water samples. Our future objective will be to aplly the optimized method to determine these nano-pollutants in water samples from Brazilian aquatic environments.

**WP195 Mobile Phase Additive Selection For Reduction of LC/MS In-Source Fragmentation of HFPO-DA**

*L. Mullin, Waters Corporation; D.R. Katz, Office of Research and Development, USEPA, Narragansett / Atlantic Ecology Division; N. Riddell, Wellington Laboratories Inc.; R. Plumb, J. Burgess, Waters Corporation; I. Ericson Jogsten, Orebro University / MTM Research Centre*

Tetrafluoro-2-(heptafluoropropoxy)propanoic acid (HFPO-DA), commonly known by the trade name GenX for the ammonium salt derivative, is a polyfluoroalkyl ether carboxylic acid introduced as replacement of perfluorinated alkanoic substances (PFAS) fomerly used in various industrial and consumer processes. Environmental monitoring of this compound has increased notably due to recently discovered prior high volume discharge by manufacturers. While liquid chromatography-tandem mass spectrometry (LC-MS/MS) using negative polarity electrospray ionization ($ESI^-$) is the preferred method of analysis, fragmentation of the molecule upon ionization and dimer formation are common observations which inhibit low detection levels in environmental matrices and potential losses in analyte specificity. This work characterized the use of various LC mobile phase additives to control the formation of the bicarbonate adduct $[M+CHO_3]^-$ of HFPO-DA. These included ammonium acetate, ammonium formate and ammonium bicarbonate (2 and 10mM); and formic acid and ammonium hydroxide (0.1 and 0.5%). All additive experiments were performed on a Waters Acquity H-Class equipped with an isolator column in line with pre-injection solvent delivery and a BEH C18 2.1x100 mm 1.7 mm analytical column. Mass spectrometry analysis and source condition optimizations were performed on a Waters Xevo TQ-D operating in both full scan and MRM modes. Adduct identity was confirmed using accurate mass measurement on a Waters Xevo G2-XS QTof. Method reproducibility was assessed by repetition of optimized conditions on additional systems and sites. In monitoring the molecule stability across all mobile phases used, the previously characterized primary fragment generated from the loss of $CO_2$ (-44Da) and additional fragments from breakage at either side of the ether linkage (-161 and -145Da) were assessed relative the parent molecule in full scan where minimal collision energy is applied. Formic acid mobile phase data showed the highest degree of molecule fragmentation. Adduct formation was most stable using the 2 mM ammonium bicarbonate and observed to reduce the degree of fragmentation contribution to overall molecular signal, as well as reduce dimer formation during ionization. An assessment of mobile phase pH from both multiple pH adjustments of ammonium bicarbonate and the inherent pH of all mobile phase compositions showed no strong correlation to in-source fragmentation increase, decrease or relative proportion to parent molecule conservation.

**WP196 Development of an analytical screening method for agricultural chemicals in drinking water using GC-MS**

*S. Takagi, Osaka Institute of Public Health / Environmental Health Section; N. Kobayashi, National Institute of Health Sciences; T. Miyawaki, Fukuoka Institute of Health and Environmental Sciences; F. Adachi, J. Yoshida, Osaka Institute of Public Health; Y. Tsuchiya, National Institute of Health Sciences; K. Kadokami, The University of Kitakyushu*

In Japan, total demand for water supply has been decreasing year on year because of a declining national population. This resulted in chronic deterioration of financial situation of water facilities and expense to maintain drinking water quality will be reduced. From the view point of chemical analysis, we have to develop cost-effective methods for drinking water quality test. By analyzing chemical compounds using a gas chromatograph-mass spectrometer (GC-MS), we obtain mass spectrum and retention time which are specific for each chemical compound and useful to determine the compound qualitatively. For quantitative analysis, creation of the calculation curve is necessary. If these information, i.e., the mass spectrum, the retention time and the calculation curve, are registered with one database, it will make it possible to analyze various chemical compounds in short time without preparing standard compounds, standard solutions and creating calculation curves. To compose efficient screening analytical methods for drinking water quality test, 176 agricultural chemicals were analyzed with six different GC-MSs using a single analytical method and the precision of the results was verified. When *m/z* which had the strongest intensity was chosen as a monitor ion, the ion agreed with all six instruments in 68% of the targeted compounds. Although the relative standard deviations of each retention time were over 1%, the value was improved to less than 1% by adjusting each relative retention time using corresponding internal standards. The calculation curves were created by one GC-MS which had lowest detection limit. Then, data of other GC-MSs were quantified using this common calculation curves and then the obtained values were compared with setting concentrations. The trueness of over half of tested compounds were within 50 to 200%. However, the values were not good in some compounds. It seems that improvement of the calculation curves is needed to better analyze the agricultural chemicals in drinking water.

**WP197 Monitoring of 176 agricultural chemicals in raw water and tap water by GC/MS screening analytical method**

*N. Kobayashi, Y. Tsuchiya, National Institute of Health Sciences; S. Takagi, Osaka Institute of Public Health; T. Miyawaki, Fukuoka Institute of Health and Environmental Sciences; K. Kadokami, The University of Kitakyushu; Y. Ikarashi, National Institute of Health Sciences*

In order to ensure the safety of drinking water, many agricultural chemicals in raw water and tap water are monitored by many of water suppliers in Japan. However, Japanese official analytical methods for the agricultural chemicals in drinking water are generally complicated. Much labor and cost is required to apply these analytical methods. Therefore, we need more simple and efficient analytical method for agricultural chemicals. In the present study, we have developed a screening analytical method for agricultural chemicals by gas chromatography/mass spectrometry (GC/MS). Then we applied the analytical method to measure concentrations of agricultural chemicals in raw water and tap water. The target compounds of the present study are 176 agricultural chemicals, which are the "Complimentary Items" in tap water in the Japanese Waterworks Act. We have measured the standards solutions of the agricultural chemicals by GC/MS, then, information of retention time, mass spectrum, and calibration curve was restored to a database. We used anthracene-$d_{10}$, 9-Bromoanthracene, and chrysene-$d_{12}$ as internal standards for GC/MS measurement. The sample preparation method is the same as the Japanese official analytical method released by the Ministry of Health, Labour and Welfare. Then, we have collected 75 raw water and drinking water samples during June to August 2018, and we apply the GC/MS screening analytical method using the developed database. As a result, we have detected 30 agricultural chemicals from raw water samples, 17 agricultural chemicals from drinking water samples. The analytical results by GC/MS screening analytical method were almost the same as those by official analytical methods. Therefore, we judged that the GC/MS screening analytical method we have developed in the present study was applicable to the analysis of agricultural chemicals in drinking water. In order to expand this GC/MS screening analytical method as a standard analytical method of drinking water, we will conduct the validity test of the analytical method among other examination organizations.

**WP198 Monitoring algal toxins in a large reservoir: Relationships with inorganic ions**

*S. Subbiah, A. Karnjanapiboonwong, T.A. Anderson, Texas Tech University / Environmental Toxicology*

Cyanobacteria are widely distributed in fresh, brackish, and ocean water environments, as well as in soil and on moist surfaces. Changes in the population of cyanobacteria can be an important indicator of alterations in water quality. Metabolites produced by blooms of cyanobacteria can be harmful, so cell counts are frequently monitored to assess the potential risk from cyanobacterial toxins. A frequent uncertainty in these types of assessments is the lack of strong relationships between cell count numbers and toxin concentrations. We monitored cyanobacterial toxin concentrations and inorganic ions in monthly water samples from a large reservoir over a 2+ year period, in an effort to determine the existence of any relationships between toxins and common ions. Cyanobacterial toxins were quantified using ELISA (cylindrospermopsin, saxitoxin) or LC-MS/MS (microcystins, anatoxin-A). Common anions and cations were determined by ion chromatography. Anion ($Cl^-$, $NO_3^-$, $SO_4^{-2}$) and cation ($Na^+$, $Mg^{+2}$, $NH_4^+$) concentrations varied by location within the reservoir. In addition, anions ($F^-$, $NO_3^-$) and cations ($Na^+$, $Ca^{+2}$) also varied by season (month). We observed seasonal changes in cyanobacterial toxin concentrations, although toxin concentrations (? microcystins) during the study period never exceeded safety limits. Attempts were made to correlate ion concentrations we measured, and water quality parameters we obtained from an EPA database, to the cyanobacterial toxin concentrations we measured. Results of our study are expected to increase the understanding of potential relationships between human activities in the study location and water quality.

### WP199 Development of a dose-response model for assessing risks from antibiotic resistant *E. coli* in agricultural water reuse

*S. Chandrasekaran, S. Jiang, University of California, Irvine*

Several recent studies have identified antibiotic resistant bacteria (ARB) and residual antibiotics in the effluent of wastewater treatment plants (WWTPs). This is especially true of WWTPs that accept effluent from hospitals or pharmaceutical manufacturers. Moreover, in addition to ARB discharged directly into the environment, the residual antibiotics in the effluent also exert a selection pressure and promote the buildup of additional ARB. This scenario is especially problematic when treated wastewater is used for agricultural irrigation in the effort towards water reuse. There is a potential for the development of infections that do not respond to antibiotic treatments. We here develop a dose-response model taking into account the portion of antibiotic resistant *E. coli* in the treated wastewater in order to understand the magnitude of the threat. In this model, we assume that in the absence of antibiotics, the ARB does not possess increased virulence. This means that the same model used for the antibiotic sensitive bacteria applies for the resistant strain. However, in the presence of antibiotics, through co-ingestion of residual antibiotics and ARB with water or food, the ARB will survive and out compete the sensitive strains. Under such scenarios, the health outcome depends on three factors: the initial bacterial dose of ingestion, fraction of ARB and the concentration of antibiotic. The key contribution of this study is a dose-response model founded in stochastic growth kinetics that accounts for these three factors in determining the health outcome. We demonstrate that the new model outperforms the existing dose-response model for *E. coli* infection in human trial studies. Predictions of human health outcomes are also made in the context of residual antibiotic quantities utilizing kinetic data from in vitro experiments of the ARB to inform the dose-response model.

## Effects of Stormwater Treatment on Receiving Water Quality

### WP200 Advances in permeable pavement technology: Implications for use and reduction of pollutants

*J.D. Stark, Washington State University / Dept of Entomology; J. McIntyre, Washington State University; C. MacKenzie, B. Leonard, Washington State University / Puyallup Research and Extension Center; C. Duchet, Washington State University / Department of Evolutionary & Environmental Biology*

Several green stormwater technologies, including bioretention and permeable pavements have been shown to be effective methods for infiltrating urban runoff, thus reducing flooding. Furthermore, results of a number of studies have shown that certain pollutants contained in stormwater are reduced after passing through specific bioretention systems. Permeable pavements include asphalt and concrete products that allow water to infiltrate into the soil beneath them. As such, they hold promise for the management of stormwater. However, a major flaw with permeable pavements is that they don't have the same durability as conventional pavements. In this study, we evaluated permeable asphalt and concrete that had been modified by adding a carbon fiber product used in the production of Boeing's 787 aircraft wing. Tensile and compressive strength of the modified pavements were compared to conventional permeable pavements. We also evaluated the removal of specific pollutants from stormwater collected from an urban freeway in Seattle. Additionally, a series of aquatic toxicity studies were conducted with untreated urban stormwater and stormwater that passed through conventional permeable asphalt and concrete and carbon-fiber modified permeable asphalt and concrete columns. Results of these studies will be discussed in this talk.

### WP201 Efficacy of compost amended biofiltration swales as green stormwater infrastructure for treatment of toxicants in highway road run-off

*B. Leonard, Washington State University, Puyallup; K. Peter, Z. Tian, University of Washington, Tacoma / Center for Urban Waters; E.P. Kolodziej, University of Washington, Tacoma/Seattle / Center for Urban Waters Interdisciplinary Arts and Sciences Civil and Environmental Engineering; N. Scholz, NOAA Fisheries / Northwest Fisheries Science Center; J. McIntyre, Washington State University; J.D. Stark, Washington State University / Dept of Entomology*

Biofiltration swales, or bioswales, use vegetated soil substrates to filter contaminants from stormwater, decrease sediment load, and reduce erosion. Following a storm, runoff moves slowly through the swale at a shallow depth. While stormwater is retained in the bioswales, pollutants are removed by the combined effects of filtration, infiltration, settling, and biotransformation. The system currently being evaluated uses the addition of compost to further enhance the ability of bioswales to remove toxicants. WSDOT has created guidelines for constructing compost amended biofiltration swales (CABS) and implemented a field test for CABS along Washington State Route (SR) 518 in 2009. As part of an ongoing study, influent and effluent samples are currently being collected at the field site during storm events and tested for metals, PAHs, pesticides, phthalates, and unknowns (LC-QTOF). Acute toxicity and sub-lethal effects of stormwater were also measured using zebrafish (*Danio rerio*) bioassays. Along with researchers from University of Washington (UW) we created a laboratory model for CABS at the Washington State University (WSU) Puyallup Research Extension Center (PREC) to verify field test results in a controlled setting and identify ways that the WSDOT design could be improved. This system is exposed to highway runoff from a previously studied high volume source off SR 520 and tested at different flow rates, swale lengths, and slope gradients. Paired chemistry and toxicology data show how stormwater treatment by CABS differ from traditional soil biofiltration methods. Results presented at Salish Sea show how zebrafish developmental biology is affected by treated and untreated stormwater and how CABS design impacts toxicant treatment efficacy.

### WP202 Sources of fine sediment particles (< 20 µm) in roadway runoff in the Lake Tahoe Basin

*H. Hwang, Texas Southern University / Department of Environmental and Interdisciplinary Sciences; M. Fiala, Texas Southern University / Department of Environmental Science and Technology / Department of Environmental and Interdisciplinary Sciences; R. Wigart, County of El Dorado*

Disturbance within the Lake Tahoe Basin has increased rapidly since the late 1950s primarily due to an extensive road network that boosted urban development and traffic related activities. The clarity of the Lake Tahoe water column has declined since then due to the increased input of fine sediment particles from the Lake Tahoe Basin. This study investigated the contribution of winter road management practices such as abrasive sand application and snow plowing to fine sediment particles (< 20 µm) in roadway runoff that enters directly or indirectly into Lake Tahoe. Roadway runoff was collected from two sites on Pioneer-Trail, a high traffic density road in the southern Lake Tahoe Basin, between November

2012 and May 2014 to identify major sources of fine sediment particles and calculate their contributions. Sieved (20 µm) runoff samples were measured for turbidity, organic matter, oil and grease, elemental composition, and molecular organic markers. The contribution of fine sediment particles from major sources such as road hillside soil, abrasive sand, pavement wear, and vegetation debris was calculated using a chemical mass balance model. The most predominant source was surface soil from road hillside that contributed 20 to 70% (43 ± 9%) of fine sediment particles. It is interesting to note that asphalt pavement wear is the second most abundant source, which accounted for 12 to 53% (31 ± 8%) of fine sediment particles. The contribution of abrasive sand (Washoe sand) ranged between 7 and 23% (16 ± 4%). Turbidity peaked (over 1,000 NTU) during the first flush and declined exponentially. In the early phase runoff, turbidity was above 200 NTU, which is problematic for discharges to infiltration systems such as trenches, ponds, vaults, and porous pavement in the Lake Tahoe Basin. These results indicate that the first 30 to 50% (by volume) of runoff needs to be treated using treatment BMPs and the later phase of runoff (at least 50%, by volume) can be rerouted to downstream locations such as infiltration systems and pervious dispersion areas. This research supports that size and treatment capacity of treatment BMPs may be reduced to save geospatial footprint and cost.

**WP203 The Effect of Stormwater Outfall Relocation on Near Surf Zone Bacterial Exceedances in Myrtle Beach and North Myrtle Beach**

*M. Carson, University of South Carolina / Environmental Health Sciences; B. Rabon, D. Graves, South Carolina Department of Health and Environmental Control / Bureau of Water; G.I. Scott, University of South Carolina / Department of Environmental Health Sciences*

Ocean water quality monitoring informs the public of waterborne pathogen-induced illness risk. This monitoring allows for informed decisions to be made on ocean water contact recreation and public health, throughout the year. The Greater Myrtle Beach Grand Strand Region, including Myrtle Beach (MB) and North Myrtle Beach (NMB), has extensive bacterial pollution ocean monitoring. In 2002, routine monitoring was implemented, in South Carolina, as part of the BEACH Act. This program involves weekly ocean water quality monitoring at NMB and MB stations during beach season. High Enterococcus bacteria levels in ocean water, have been linked to an increased risk in human illness. Beach monitoring and issuance of timely advisories are key in the reduction of public health risk, related to ocean water exposure. Recent MB and NMB monitoring data indicated frequent exceedances of Enterococcus water quality standards with primary pollution sources emanating from nearshore storm water discharges. Thus, to reduce near shore bacteria loads, storm water outfall discharges were relocated offshore 1,000+ feet. Our study's goal was to determine if outfall relocation from on the beach to more than 1,000 feet out into the ocean had an effect on the number bacterial standard exceedances. To this end, we analyzed mean levels of both Enterococcus abundance and the percent exceedances for the Enterococcus Single Sample maximum Standard (104 cfu/100ml). Samples were compared before and after the outfalls were relocated. To discern differences alpha levels of 0.10-0.25 were used. Ten stations were examined between Myrtle Beach (N=5; WAC-018-WAC-024) and North Myrtle Beach. (N=5; WAC-005A-WAC-009).After outfall relocation, both MB and NMB areas demonstrated significant differences in Enterococcus levels. Generally, most examined outfalls had reduced levels of microbial pollution. The overall Enterococcus exceedances and average number of Enterococcusbacteria were reduced after outfall relocation. Taken together, our results suggest that ocean outfall implementation in Myrtle Beach and North Myrtle Beach, and the movement of storm water to further offshore locations could successfully decrease nearshore surf zone high bacteria incidences. Minimizing human contact with high-level bacteria pollution is essential for creating a safe, recreational environment for people to use and enjoy the ocean and beaches.

**WP204 A 30 Year Trend Assessment of Fecal Indicator Bacteria (*Escherichia coli* and Enterococci) Along the Shoreline of Santa Monica Bay, California**

*C. Enyart, J. Dorsey, Loyola Marymount University; K. Johnston, The Bay Foundation; D. Berube, Loyola Marymount University*

Santa Monica Bay and its vast beaches are important Los Angeles icons, while also providing significant ecosystem services to over millions of recreational visitors annually. Contaminated runoff from numerous watersheds surrounding the Bay, especially the 87% urbanized Ballona Creek Watershed, have historically resulted in poor water quality along areas of the Bay shoreline. Decades of monitoring for fecal indicator bacteria (FIB) along the Bay's shoreline has been associated with NPDES wastewater discharge and stormwater programs. Many projects have been implemented throughout the watersheds (e.g. sewer improvements, biofiltration systems, low-flow diversions (LFDs)) to lessen flows of runoff from contaminating surf zone recreational waters. Despite decades of monitoring, there has been no long-term assessment of trends in shoreline FIB, especially in response to implementation of projects to improve water quality. The goal of this study was to assemble 30 years of monitoring data (1988-2017) for *E. coli* and enterococci to assess trends along the entire shoreline of Santa Monica Bay. Raw data were acquired from various monitoring agencies to develop a data file that included 82 stations covering a set of about 150,000 observations (cfu or MPN/100 ml) for *E. coli*, and a similar number for enterococci. Data were analyzed by calculating rolling 30-day geometric means, and comparing means by geographic subdivision, between wet and dry weather, and over time. Resulting trends for both *E. coli* and enterococci were: 1) concentrations peaked around 2005 when many stations shifted to sampling points where runoff mixed directly with surf zone water; 2) after 2005, concentrations fell to present levels, especially at beaches where LFDs were implemented; 3) concentrations were extremely variable during the 2016-17 wet season; 4) the north and central areas of the Bay, impacted by runoff from the Ballona Creek and Malibu Creek Watersheds, had greater concentrations relative to the south area; and 5) dry weather concentrations were less than the TMDL standard of 35 MPN/100 ml, but did exceed this limit occasionally during wet weather in the central bay. Implementation of LFDs and other best management practices to restrict polluted runoff from flowing into the surf zones of the Bay's beaches most likely improved water quality throughout the Bay.

**WP205 Is dust a major transporter of synthetic pyrethroids in residential areas?**

*V.J. Pettigrove, The University of Melbourne / Sciences; D. MacMahon, CAPIM The University of Melbourne / Biosciences*

The synthetic pyrethroids (SPs) bifenthrin and permethrin have been detected in sediments of urban waterbodies throughout Melbourne, Australia and are often at concentrations that are toxic to fish and macroinvertebrates. Highest concentrations of these pesticides are often present in sediments from waterbodies near new residential developments where SPs are applied to houses to prevent termites infestation. Although these developments have swales, wetlands and other devices to intercept and treat urban stormwater, SPs are often present downstream of these treatment systems. A study was conducted to determine what were the major causes of SPs pollution from termite treatments, to understand how SPs enter local waterbodies and what can be done to reduce SP pollution from these activities. The termites can only access buildings through subsurface soils, so treatments involve creating a physical or chemical barrier around buildings. Chemical treatments are the preferred option on almost all houses. These include installing sheets impregnated with a SP, the use of an irrigation system primed with SPs and directly spraying the SPs around the perimeter of the building. To assess the contribution of surface runoff to pollution, 48 houses from 4 housing estates were monitoried for SPs in soil collected from within 50 cm of each building and from near the footpath where is was evidence of water runoff. Samples were collected at the start of construction, once construction was completed and the house was occupied and 6 months afterwards when the garden was usually more established. Soils were also collected from street gutters upstream and downstream of houses. Dust was collected from power boxes (~1.5m high X 2 X 3m) and other elevated structures. Bifenthrin, permethrin and occasionally cypermethrin were present in soils near buildings after SPs had been applied. Usually a small fraction of SPs was present in soils near the footpath where there were signs of surface runoff. Soils present in gutters, including those upstream of houses, also contained SPs. Dust also contained elevated concentrations of SPs. A strong correlation exists between SP concentrations in dust and the number of houses within a 50m radius of the site. Dust collected from the surface of power boxes more than 5km away from new housing estates also was contaminated with SPs, suggesting that dust can transport these substances long distances.

**WP206 Assessing Stormwater Impacts and Mitigation Measures in California's Areas of Special Biological Significance**

*K.C. Schiff, Southern California Coastal Water Res.*

The coastal environment of California is home to diverse and abundant marine life comprising some of the richest aquatic habitats on earth. In order to protect this valuable resource, the State has created 34 marine water quality protected areas termed Areas of Biological Significance (ASBS). Despite the prohibition against waste discharge and the mandate to maintain "natural water quality" in these marine water quality protected areas, nearly 1,700 stormwater outfalls exist in ASBS statewide. This project covers a five-year period tackling three critical management knowledge gaps. First, based on over 110 wet weather site-events at reference sites, natural water quality was translated from a narrative water quality standard to receiving water numerical thresholds. Second, based on more than 140 wet weather site-events, receiving water samples were collected near stormwater discharges into ASBS. The frequency, extent, and magnitude of stormwater impacts in these water quality protected areas was assessed using the reference-based numerical thresholds. All 34 ASBS statewide observed some level of impact, not necessarily co-varying with rainfall quantity, intensity, antecedent dry period or land use. Finally, more than $34 million (US) in State Water Bond grants was spent on stormwater infrastructure improvements and best management practices (BMPs). Monitoring of these BMPs was used to assess the effectiveness and efficiency of stormwater treatment and improvements to discharges into the State's water quality protected areas.

## Selenium Ecotoxicology and Management Going on 40: What Do We Know and How Can We Apply It?

**WP207 Toxicity of Aqueous L-Selenomethionine Exposure to Early Life-Stages of Zebrafish**

*A.K. Gerhart, University of Saskatchewan / Toxicology Centre; D.M. Janz, University of Saskatchewan / Veterinary Biomedical Sciences*

Selenium (Se) is an important micronutrient involved in numerous metabolic functions in vertebrates. However, its narrow range between essentiality and toxicity has generated concern due to elevated environmental concentrations. Numerous studies have shown that oviparous vertebrates, fishes in particular, are highly susceptible to elevated dietary selenium concentrations during early development due to maternal transfer. Exposure to seleno-L-methionine (SeMet), the predominant form of Se in the diet, during early life stages can induce teratogenic effects such as spinal deformities (lordosis, kyphosis, and scoliosis), edema, and fin and craniofacial malformations, as well as increase the incidence of mortality in developing fish larvae. Previous studies have largely consisted of dietary exposures, yolk microinjections, and aqueous exposures with juvenile or adult fish, with more recent work using aqueous embryo exposures. However, research comparing the effects of yolk microinjections to aqueous embryo exposures has yet to be conducted. Using *Danio rerio* as a model test organism, we sought to evaluate the effects of elevated SeMet, in solution, on developing embryos exposed during early life stages. Newly fertilized zebrafish embryos between 1– 3 hours post fertilization were aqueously exposed to graded concentrations of Se (5, 25, and 125 µg/L, ten replicates/treatment, 20 larvae/replicate) as SeMet for 5 days. Survival, hatchability, time to hatch, as well as the frequency and severity of deformities (total and type) were quantified. Whole-body Se concentrations were also determined in swim-up fry following the 5-day exposures. Although experiments are still ongoing, preliminary research suggests that exposure to SeMet, in solution, produces a dose-dependent increase in both the incidence and severity of deformities in developing zebrafish larvae. Through comparisons to other methods of exposure, this research has the potential to determine whether aqueous exposures represent a valid replacement for other labortaory methods of Se exposure such as spiked diets or yolk microinjections.

**WP208 Relative Sensitivity of Sculpin to Environmental Selenium**

*S. Covington, Formation Environmental; M.C. Lewis, Formation Environmental LLC; A. Prouty, JR Simplot*

In 2006, the J.R. Simplot Company began working toward the development of a site-specific selenium criterion (SSSC) for streams near one of its southeast Idaho mines. Relative sensitivity of resident fish is an important factor in developing the SSSC. Fish species present at the site include Brown Trout (BT), Yellowstone Cutthroat Trout (YCT) and Sculpin (primarily Pauite sculpin [*Cottus beldingi*], with many fewer mottled sculpin [*C. bairdi*]). Site-specific toxicity testing showed that BT were more sensitive to developmental toxicity from selenium than YCT, and are likely the most sensitive aquatic species present. Whole-body selenium EC10s (survival and development) were 13.5, and 14.5 mg/kg dw for BT and YCT, respectively. Sculpin were not included in toxicity testing, but data on population density (i.e., individuals per unit area), abundance within age classes, and whole-body selenium concentrations were available for an 11-year period, and were used to assess the relative selenium sensitivity compared to the trout species. Whole-body selenium concentrations in sculpin exceeded those in trout, with average concentrations ranging up to about 27 mg/kg dw in selenium-affected sampling locations. Sculpin population (density and age class frequency) was not affected in a dose-dependent manner relative to selenium in surface water or whole-body tissues. The relative proportion of populations represented by the youngest, and most likely affected, age class (years 1 and 2, length < 60 mm) was unrelated to whole-body selenium concentration from 2 to 27 mg/kg dw. Age class 3 and 4 (length 60-90 mm) sculpin represent fish that have survived to reproductive age. While abundance of this age class fluctuated year-to-year at both background and selenium-affected sampling locations, the mean abundance in 2013 was similar to 2006, despite increasing selenium concentration in whole-body and surface water. The variability was not correlated with whole-body selenium concentrations or selenium concentrations in surface water at the most selenium-impacted locations. The population and age-class endpoints are not directly comparable to developmental toxicity endpoints, but the apparent lack of effect of high whole-body selenium concentrations on key population metrics indicate that sculpin may be more tolerant of selenium toxicity than YCT.

**WP209 The Mystery of the Naturally Selenized Fish**

*L. Ashby, University of Ottawa / Earth Sciences; K. Hille, M. Bromstad, S. Earle, K. Salzsauler, Golder Associates, Ltd.; A. deBruyn, Golder Associates, Ltd. / Environmental Science*

Baseline studies in a pristine oligotrophic lake in northern British Columbia found that resident rainbow trout (*Oncorhynchus mykiss*) had tissue selenium concentrations exceeding health-based consumption guidelines, despite aqueous selenium concentrations less than 1 µg/L. We conducted a study to identify the source of selenium to these fish. Selenium speciation analysis of sediment cores and dialysis array ('peeper') water samples across the sediment-water interface indicated that lake sediments were a net sink, not source, of selenium. Organoselenides were present in all tested surface sediment samples. Gut content and stable isotope analysis revealed that rainbow trout (the only fish species present in the lake) were broadly omnivorous, feeding predominantly on planktonic, benthic, and littoral invertebrates. Selenium analysis of potential prey in several areas of the lake identified few taxa with sufficiently high concentrations to explain concentrations in rainbow trout. Most invertebrates, including those that predominated in fish guts, had tissue selenium concentrations less than 5 mg/kg dw, whereas rainbow trout had muscle selenium concentrations ranging from 7 to 28 mg/kg dw and egg selenium concentrations up to 48 mg/kg dw. Benthic chironomids and littoral caddisflies had distinctly higher concentrations than other taxa, up to 17 mg/kg dw. However, approximately 20% of rainbow trout captured had tissue selenium concentrations too high to be explained by the invertebrate prey sampled. A possible explanation is cannibalism. One fish gut contained a juvenile rainbow trout and the highest-selenium fish also had elevated $\delta^{15}N$, consistent with feeding on juveniles. Our data suggest that the high baseline fish tissue selenium concentrations may have resulted from preferential feeding of juveniles on high-selenium invertebrate prey and cannibalistic feeding of adult rainbow trout on those juveniles.

**WP210 Sensitivity of Arctic Grayling (*Thymallus arcticus*) Larvae Exposed to Selenium via Maternal Transfer**

*D.K. DeForest, Windward Environmental, LLC; J. Baker, Nautilus Environmental; B. Morris, K. Ferry, Owl Ridge Natural Resource Consultants, Inc.; J. Elphick, Nautilus Environmental; R. Napier, Teck Alaska Incorporated; K. Brix, EcoTox / Marine Biology and Ecology*

Selenium toxicity to fish is primarily manifested via maternal transfer to the eggs, which may result in adverse effects on larval survival and development. In this study, gametes were collected from Arctic grayling (*Thymallus arcticus*) collected from Alaska streams with a range of selenium exposure concentrations. Eggs were fertilized and reared in the laboratory from hatch through post-swimup. Larvae were assessed for survival, length, weight, and deformities (skeletal, craniofacial, finfold) and edema based on a graduated severity index (GSI). No adverse effect relationships were observed between larval endpoints evaluated and parent females' egg, muscle, or whole-body selenium concentrations. Therefore, selenium toxicity thresholds (10% effect concentrations [EC10s]) were defined as the maximum measured selenium concentrations: >33.9, >17.6, and >19.7 µg/g dry weight for eggs, muscle, and whole-body tissue, respectively.

**WP211 Factors influencing selenium uptake by periphyton in boreal lake ecosystems**

*M.D. Oldach, University of Saskatchewan / Toxicology Centre / Veterinary Biomedical Sciences; D.M. Janz, University of Saskatchewan / Veterinary Biomedical Sciences*

Selenium is an essential trace element with a narrow margin between essentiality and toxicity in many organisms. Selenium is a contaminant of concern in the boreal forest region of North America because certain industrial practices release selenium into cold-water aquatic environments. Selenium is rapidly assimilated into food webs by primary producers, including algae, bacteria, and fungi, and transferred to higher trophic levels through dietary pathways. There are significant site-specific differences in the uptake of selenium into food webs by primary producers, which can have implications for higher trophic levels. Therefore, the objective of this study is to diminish this uncertainty through quantifying selenium uptake at the base of the food web in representative boreal lake ecosystems. This will be achieved by 1) investigating if there are concentration-dependent differences in periphyton enrichment functions of selenium, and 2) determining if water chemistry plays a role in selenium uptake by periphyton. Textured glass plates were deployed in 5 lakes with varying levels of dissolved organic carbon and total phosphorous at the IISD-ELA (International Institute for Sustainable Development-Experimental Lakes Area). After a growth period of 6-8 weeks, plates were exposed to environmentally relevant concentrations of selenium (control [0.1-0.2], 0.5, 1, 2, 4 µg Se/L) as selenite, and allowed to incubate in a static renewal system under ambient conditions for 8 days. Aqueous dissolved and total selenium concentrations, selenium accumulation in periphyton tissues, and periphyton community structure were quantified. The results of this research will provide insight on the biodynamics of selenium assimilation at the base of boreal lake food webs, which can potentially inform ecological risk assessment in cold freshwater ecosystems in North America.

**WP213 Selenate versus selenite – uptake into algae and trophic-transfer to *Daphnia magna***

*C. Rickwood, M. King, E. Suominen, G. Prabhakar, Natural Resources Canada*

The uptake of Selenium from water to primary producers has generally been accepted as the most important stage in the toxicity of Se, due to accumulation and conversion to the organic form Se-methionine. The objective of this study was to determine whether speciation of Se in water is important in determining trophic-transfer and toxicity. This presentation will provide a comparison between Selenate and Selenite exposed algae and the effects of dietary exposure to the cladoceran *Daphnia magna* over two-generations. An algal diet, consisting of both *Chlorella kessleri* and *Pseudokirchneriella subcapitata* was spiked in a dose-dependent manner with Selenite and Selenate over a 7-day growth period resulting in a dietary-Se exposure of 5, 20 and 80 mg/kg Se (Nominal Concentrations). Selenium speciation in growth media during 7-days and total Se in algae was measured to determine dietary exposure concentrations. First generation *D. magna* were fed Se-spiked algae over a 21-day period to assess survival and reproduction. Offspring were collected and either exposed to dietary-Se or a control diet for a further 21-days. Tissue concentrations of both 1st and 2nd generation *D. magna* were assessed as well as visual inspection of the daphnids for any potential deformities. A comparison of algal uptake, speciation in growth media, daphnid reproduction, survival and tissue Se concentrations, including trophic-transfer factors, will be presented.

**WP214 Development of a Draft Selenium Aquatic-Dependent Wildlife Ambient Water Quality Criterion for the State of California**

*A. Jarvis, J. McLaughlin, B. Schnitker, J.R. Beaman, K. Gallagher, USEPA / Office of Water; D. Oros, USEPA Region 9*

Selenium is found in aquatic ecosystems in California. At low concentrations, selenium is an essential nutrient. However, selenium concentrations slightly above beneficial levels can be harmful to wildlife (Ohlendorf 2003). The bioaccumulation of selenium through the aquatic food web can affect consumers and predatory organisms. Along with other oviparous vertebrates, such as many fish, birds appear to be particularly sensitive to selenium exposure. Malformations and reproductive impairments have been observed at environmentally relevant concentrations in aquatic-dependent bird species (Ohlendorf et al. 1986; Hoffman et al. 1988). USEPA has initiated development of a selenium aquatic-dependent wildlife criterion focused on California ecosystems using latest scientific literature and building upon the approach developed in the national 2016 USEPA Aquatic Life Selenium Criterion.

**WP215 Preliminary Risk Assessment for Avian Exposure to Selenium at Lake Koocanusa, Montana**

*J.P. Skorupa, K.J. Nelson, US Fish and Wildlife Service / Environmental Contaminants Program*

Lake Koocanusa is a trans-boundary reservoir in northwestern Montana and southeastern British Columbia, created in 1972 with the completion of Libby Dam on the Kootenai River. Coal mining operations in the Elk Valley watershed of British Columbia discharge selenium (Se) into the Elk River, a major tributary to Lake Koocanusa. Annual Se loads entering Lake Koocanusa have increased from 2,600 kg in 1992 to over 13,000 kg in 2012, more than a fivefold increase. The Montana Department of Environmental Quality has listed Lake Koocanusa as impaired for Se under sec. 303(d) of the Clean Water Act, and fish tissues often exceed risk benchmarks for fish. Aquatic ecosystems that exceed Se toxicity benchmarks for fish tissue also present the potential for toxicological risk to aquatic-dependent birds; however, no systematic surveys of avian breeding activity or sampling of avian tissues had been conducted at Lake Koocanusa in Montana. During the breeding season of 2016 a multi-agency team of biologists conducted a reconnaissance survey of nesting birds at Lake Koocanusa and collected a small set of shorebird eggs for Se analysis. Previous research on Se in shorebird eggs along the Elk River showed a strong declining gradient of exposure as a function of distance from the coal mines, and our results for shorebirds at Lake Koocanusa matched-up with that gradient. We also conducted a Monte Carlo analysis of pre-existing egg data from the Elk River watershed to estimate a site-specific toxicity benchmark for shorebird eggs that revealed our results were well below that estimated toxicity benchmark. Swallows are the second most abundant type of nesting bird at Lake Koocanusa. In the absence of egg samples for this taxonomic group, we conducted an indirect assessment based on an array of other Se contaminated sites with exposure information for co-occurring shorebirds and swallows that allowed a working hypothesis to be generated for expected Se exposure in swallow eggs at Lake Koocanusa. Combined with Se response data for swallows from the literature, our working hypothesis suggests that collecting Se exposure data for swallow eggs at Lake Koocanusa is a warranted follow-up avian research priority. However, both the direct assessment for shorebirds and the indirect assessment for swallows suggest that Se exposure of fish, not birds, will be the most vulnerable biological endpoint to focus on for setting a site-specific water quality standard.

**WP216 Developing Site-Specific Selenium Criteria: Challenges and Lessons Learned**

*S. Covington, Formation Environmental; A. Prouty, JR Simplot*

In 2006, the J.R. Simplot Company began working toward the development of a site-specific selenium criterion (SSSC) for streams near one of its southeast Idaho mines. At that time, the selenium standard in Idaho was a water value of 5 ug/L. Developing information at that time from the scientific and regulatory community suggested that a new selenium criterion should be based on the response of organisms relative to their tissue concentrations. The consensus indicated that selenium is bioaccumulated through dietary intake and effects are manifested in the developing young, thus exposure is primarily dietary, not water borne, and tissues are the best measure of exposure. In 2016, the USEPA released its National Selenium Criterion for water based on a four-part criterion that included thresholds for egg/ovary, whole body/muscle, and water elements. The following year, Simplot put forth a proposal to Idaho DEQ for a SSSC based on an egg effect threshold for brown trout. Simplot's proposal used the USEPA criteria format to derive criteria for egg/ovary and whole-body fish tissues, and water using site-specific data. Idaho DEQ vetted the SSSC initially through a workgroup convened to help guide the process, and later through its formal rulemaking process which included public comments and reviews from individuals and state and federal agencies. In between these two processes, additional vetting was conducted by USEPA and USFWS. Following multiple comment periods, meetings, and reviews, Idaho DEQ adopted the SSSC with revisions, and submitted the rulemaking to the Idaho legislature for adoption. This presentation will provide some unique perspectives on the SSSC development process, derivation of the proposed criterion as well as the proposal and rulemaking process. Through navigating these processes, Simplot has compiled some "lessons learned" that may be useful to other entities that choose to undertake the SSSC process.

**WP217 Large-scale selenium remediation by ecosystem manipulation: N-P fertilization of a mine-pit lake stimulates anaerobic Se reduction**

*A. Luek, University of Lethbridge / Department of Biological Sciences; D.J. Rowan, Environmental Science Branch, Canadian Nuclear Laboratories; J.B. Rasmussen, University of Lethbridge / Department of Biological Science*

Open-pit coal mining can introduce selenium (Se) rich leachate to watersheds receiving surface runoff from the surrounding mined landscape. The associated watersheds often require large-scale, long-term treatment to mitigate Se toxicity in order to protect the health of aquatic life downstream. End-pit lakes are a standard mine-closure method for surface coal mining. Hence a vast number of these waterbodies remain in the landscape long after mining activities cease. End-pit lakes continuously accumulate Se from the surrounding watershed. High water residence times in the pits require new methods for Se management and remediation, as current practices are predominantly based on flowing water. To reduce Se in an end-pit lake, we applied the principles of anaerobic bacterial bioreactors, previously successful in small scale Se mitigation, to a whole pit lake ecosystem. The fertilization of a pit lake with N and P increased primary production, which established a meromictic anoxic layer, when senescing algae sank and decomposed. The increase of this anoxic layer enhanced habitat for locally present, anoxic, Se and sulfur respiring bacterial communities. Anaerobic microbial reduction processes then reduced Se-oxyanions by ten-fold within two years post fertilization to below water-quality guideline values. This successful application of a small scale bioreactor principle to a whole lake ecosystem allows for a low maintenance treatment of large quantities of mine drainage water, suitable to be utilized even in remote environments. A review of more than 50 coal mining end-pit lakes in Alberta, Canada showed approximately 60% of the lakes to have physical and chemical environments suitable for the here described treatment method. With high numbers of Se contaminated, new and legacy end-pit mine lakes globally, direct lake ecosystem manipulation could provide an inexpensive method for the management and reduction of a persistent aquatic contaminant in situ.

## Exposure to Crude Oils: Linking Laboratory Endpoints to Field Observations

**WP218 Toxicological assessment of a novel unimolecular micelle nanoparticle for oil dispersant using Fathead minnow, embryos and juveniles**

*H. Kurita Oyamada, Center for Environmental & Human Toxicology / Physiological Sciences; E. Oruc, University of Cukurova / Department of Biology; K.J. Kroll, University of Florida / Physiological Science; W. Reed, Tulane University / Department of Physics; S. Grayson, Tulane University / Department of Chemistry; D.A. Savin, University of Florida / Department of Chemistry; N.D. Denslow, University of Florida / Physiological Sciences*

Chemical dispersants have been used as a tool to remediate oil spills. However, traditional chemical dispersants depend on their concentration to form micelles to disperse oil, also called their Critical Micellar Concentration (CMC). Furthermore, there is an increasing demand to use environmentally friendly oil dispersants with high ability to clean up oil without toxicity. The aim of this project is to analyze the effects of a novel unimolecular micelle, engineered based on a silica nano-sized core with amphiphilic branches, conferring to the nanoparticle (NP) the characteristics of a traditional oil dispersant but without the need of achieving a CMC. Furthermore, as the NP can encapsulate better the organic compounds, their toxicity could be decreased. Fathead minnow embryos (~24hpf) and juveniles (10dph) were exposed to NPs resuspended in two different media: one to test the toxicity of NP alone, and a second to test toxicity of an oil spill simulation using the oil water accommodated fraction (WAF) mixed with NPs at concentrations of 2 mg/L, 10 mg/L, and 50 mg/L. WAF was made after weathering for one week crude oil with 20% Hank's solution (27.348 mM NaCl, 1.073 mM KCl, 0.0493 mM $Na_2HPO_4$, 0.0881 mM $KH_2PO_4$, 0.2523 mM $CaCl_2$, 0.196 mM $MgSO_4$, 40.833 mM $NaHCO_3$ ) to make a final concentration of 1 ml/L. NPs were resuspended with sonication into Hank's (20%) and then used as is or mixed with WAF 24hrs prior use. Exposures treatments were done in quadruplicate, with daily 50% solution changes for a total of 96 h. Mortality was monitored and removed on a daily basis. Toxicological endpoints assessed were embryo malformation, embryo heartbeat and in both stages gene expression of *cyp1A*, a gene that is transcriptionally activated after exposure to polyaromatic hydrocarbon compounds in crude oil. Preliminary results among embryos showed that the treatment with WAF and 2 mg/L of NP increased mortality. Furthermore, a significant decrease in heartbeat was observed with 2 mg/L NP treatment alone, WAF alone and WAF with 10 mg/L of NP (p< 0.001). Toxicity related effects were seen only on embryos, highlighting the sensitivity of this life stage. Experiments to measure internal bioavailability of oil in terms of gene expression are in progress. These preliminary results show that low concentration of NP alone and with WAF have some effects to fathead minnow embryos.

**WP219 Reproduction defects and tumorigenesis risk in *Caenorhabditis elegans* following exposure to crude oil-dispersant mixture**

*X. Pan, T. Thornburg, East Carolina University / Biology; Y. Zhang, East Carolina University*

The crude oil mixed with dispersant used in cleanup efforts represent a well-defined mixture entity that warrants investigations of its potential toxicity and health risks. Previously we have reported that the exposure to crude oil and the dispersant mixture induced reproduction defects such as decreased brood size, increased germ cell apoptosis, and abnormal spermatogenesis in *Caenorhabditis elegans* (*C. elegans*). Here, we report our new findings on the crude oil-dispersant mixture induced reproduction toxicity. Long-term exposure of *C. elegans* male strains to oil-dispersant mixture results in abnormal spermatid morphology and less motility of mature sperms. Furthermore, we utilized puf-8; lip-1 tumor sensitive strain to test the cell fate of immature sperms induced by Dis-Oil mixture treatment. Our study suggests that oil-dispersant mixture induce tumorigenesis in puf-8; lip-1 strain of *C. elegans* in a dose and temporal dependent manner. The related gene expression and microRNA-mediated mechanism will also be discussed.

**WP220 Monitoring of PAHs in shellfish after oil spill from the Sanchi tanker; comparison of polluted conditions with other spill accident using ChemTHEATRE**

*S. Uno, M. Kawano, Kagoshima University / Faculty of Fisheries; T. Isobe, National Institute for Environmental Studies / Center for Environmental Health Sciences; I.C. Handoh, Niigata University / Graduate School of Science and Technology; N. Ohno, University of Hyogo / Graduate School of Simulation Studies; T. Kunisue, Ehime University / Center for Marine Environmental Studies; K. Nakayama, Ehime University*

Until now, there have been countlessly the monitoring data for chemical contaminants. However, most of them perhaps ineffectively utilized, because their data were sometimes reported only a part without supplemented data and difficult to find the required data effectively. ChemTHEATRE (http://chem-theatre.com/) is the platform to deposit and visualize monitoring data of environmental contaminants. ChemTHEATRE describes that this database will ensure traceability of chemicals and help to simulate the environmental behavior and fate, or assess the risk. On January 2018, the *Sanchi* tanker sank off the coast of Okinawa, Japan. Most of condensate for 136,000 *ton* put in the tanker spilled and could diffuse around Japan. In addition, the heavy oil perhaps spilled from Sanchi had been drifted at coastal areas of Amami and Takara Islands, Japan from February 2018. In this study, we collected biological samples as shellfish at some locations of both islands on March 2018, and investigated PAH concentrations these. In this spill accident, it is difficult to distinguish whether the pollution is serious or not. Therefore, we also will try to compare the polluted condition with PAHs in aquatic organisms between Sanchi accident and other spill recorded in ChemTHEATRE, for example, oil spill off the coast of Guimaras Island, Philippines 2006.

**WP221 The BOREAL Project: Preliminary results from a simulated spill of diluted bitumen in boreal lake enclosures**

*J. Rodriguez Gil, University of Ottawa / Department of Biology; T. Black, University of Manitoba; J. Cederwall, Queens University / Biology; D.M. Orihel, Queens University / Department of Biology/ School of Environmental Studies; M.L. Hanson, University of Manitoba / Department of Environment and Geography; V. Palace, IISD-Experimental Lakes Area; L. Cundall, University of Ottawa; J. Mason, Queens University; S.A. Patterson, Queens University / Department of the Enviornmental Studies; L. Timlick, University of Manitoba / Department of Environment and Geography; B. Hollebone, Environment and Climate Change Canada; S. Stoyanovich, University of Ottawa; J. Séguin, J.M. Blais, University of Ottawa / Biology*

In recent years, a number of reports by the US National Academies, the Royal Society of Canada, and United States Geological Survey and among others, have highlighted the numerous knowledge gaps that currently exist in relation to the weathering, fate, behaviour, and environmental effects of diluted bitumen (dilbit) after a potential spill into aquatic systems. These reports emphasized the need for field research to address these gaps, with special need for data on freshwater systems. After a successful pilot study in 2017, the BOREAL project (Boreal lake Oil Release Experiment by Additions to Limnocorrals) set up to address some of these research needs in the summer of 2018 with a first-ever, large-scale, field simulation of a dilbit spill in a boreal freshwater system. Nine 10-m diameter, 157 m3, enclosures were set up in lake 260 at the International Institute for Sustainable Development's Experimental Lakes Area (IISD-ELA). A regression design with 2 controls and 7 oil treatments was used to assess the weathering, fate, behaviour, environmental effects and bioaccumulation potential of dilbit and its components. Nominal treatments ranged from 1.6 to 160 L of dilbit, resulting in oil:water ratios ranging between 1:100,000 to 1:1000. This talk will present a summary of initial findings from all components of the project (oil fate and behaviour and ecotoxicological effects) paying special attention to semi-quantitative data on the general behaviour of the oil (e.g. floating vs sinking) throughout the 80 days of the study.

**WP222 Understanding the effects of diluted bitumen in fresh waters through experimental oil spills: Preliminary findings on microbial communities**

*D.M. Orihel, Queens University / Department of Biology / School of Environmental Studies; J. Cederwall, Queens University; C. Greer, National Research Council of Canada; S. Higgins, IISD-Experimental Lakes Area; M.L. Hanson, University of Manitoba / Environment and Geography; B. Hollebone, Environment and Climate Change Canada; J. Mason, Queens University; A. Ortmann, Fisheries and Oceans Canada; V. Palace, IISD-Experimental Lakes Area; J. Luis Rodriguez Gil, University of Ottawa; R. Rooney, University of Waterloo; J.M. Blais, University of Ottawa / Biology*

The overall goal of the BOREAL (Boreal lake Oil Release Experiment by Additions to Limnocorrals) study is to advance our understanding of the fate and effects of diluted bitumen (dilbit) in freshwater ecosystems in Canada. We have conducted a series of aquatic mesocosm experiments at the IISD-Experimental Lakes Area, a unique freshwater research facility situated in north-western Ontario. In 2017, we performed a pilot study using three land-based 2-m diameter microcosms, and in 2018 an in-lake study using nine 10-m diameter limnocorrals was executed. Two of the questions we aimed to answer were: (i) what are the effects of dilbit on the structure and function of microbial communities?; and (ii) what role do microbial communities play in the fate of dilbit in freshwater ecosystems? To address the first question, we used a multifaceted approach, from genomics to microscopy, to examine changes in the biomass, species composition, and diversity of bacteria, viruses, and phytoplankton in response to a comprehensive range of dilbit spill scenarios (i.e., oil-to-water ratios from 1:100,000 to 1:000). We also quantified important ecosystem functions such as primary production and decomposition. To address the second question, we imaged oil-particle aggregates to elucidate the role of phytoplankton in oil sedimentation and employed transcriptomics to better understand the role of bacteria in oil degradation in freshwater ecosystems. In addition to advancing our understanding of dilbit fate and toxicity in fresh waters, we anticipate the results of the BOREAL study will inform evidence-based policy decisions and sound environmental monitoring programs.

**WP223 The effects of diluted bitumen with and without dispersants on Pacific marine benthic organisms**

*C.J. Kennedy, K. Rhodenizer, Simon Fraser University / Biological Sciences*

The higher-level effects of diluted bitumen (dilbit), dispersed dilbit, and dispersant (Corexit 9500A) exposure to marine benthic species was examined. Water accomodated fractions of dilbit (WAF) or chemically enhanced WAF (CEWAF; dispersed WAF) were generated using the CROSERF method. The susceptibility of different groups of marine benthic organisms in acute toxicity tests varied from being relatively non toxic at 100% WAF to lethal at less than 5% dilutions. CEWAF was always more toxic to all species compared to WAF alone, however the magnitude of CEWAFs higher toxicity was not the same in all species. Susceptibility trends for WAF were Kelp (*Macrocystis pyrifera)*> Echinoderm (*Strongylocentrotus purpuratus)*> mysid (*Mysidopsis bahia)*= amphipod (*Eohaustarius estuarius*) = polychaete (*Alitta virens*) > spot prawn (*Pandalus platyceros*) = tidepool sculpin (*Oligocottus maculosus*). LC50 values for the latter 2 organisms could not be determined for WAF. Several performance abilities showed significant alterations in organisms upon exposure. WAF/CEWAF at any dilution did not affect the proportion of prawns that molted. Prawns, amphipods and polychaetes-responded variably to the presence of low concentrations of dilbit; some organisms were either not able to detect, or to respond to dilbit suggesting a greater risk of exposure (particularly if attracted). Most organisms detected and avoided CEWAF and Corexit. These studies also show that behaviours including olfactory ability in prawns, and burrowing behaviour in amphipods and polychates is affected by exposure to WAF, CEWAF, and Corexit. This toxicity data provides useful information for assessing the risks of diluted bitumen, dispersed bitumen and dispersants to benthic marine organisms.

**WP224 The effects of non-dispersed and dispersed diluted bitumen on the tidepool sculpin (*Oligocottus maculosus*)**

*S. Modares, E. Ardeshirlarijani, C.J. Kennedy, Simon Fraser University / Department of Biological Sciences*

Canada is the sixth largest oil producing country in the world, with an average output of 197,000 $m^3$/d of bitumen mostly from oil sands in northern Alberta. Canadian pipeline companies have proposed a number of major new transmission pipelines from this area and new marine terminal development for tanker export of bitumen to overseas markets increasing the potential risk of a marine spill. Few studies exist on the potential lethal and sublehthal toxicity of dilbit to any marine organism. Key information from toxicological studies of crude oil and its components such as BTEX and PAH may be applied to dilbit, however, generalizations on risk cannot be made with any certainty. Water accomodated fractions of dilbit (WAF) or chemically enhanced WAF (CEWAF; WAF dispersed with Corexit 9500A) were generated using the CROSERF method. Young adult tidepool sculpin (*Oligocottus maculosus*) were exposed to varying dilutions of WAF, CEWAF or concentrations of Corexit 9500A for >12 weeks. Acute toxicity and sublethal effects were examined at various levels of biological organization from the biochemistry to behaviour. WAF was not acutely toxic to sculpins, however both CEWAF and Corexit exposures resulted in mortality and the generation of LC50 data. Exposure to WAF, CEWAF and Corexit caused a short-term stress response and an increase in oxygen consumption. Exposure to CEWAF and Corexit reduced growth by the end of the exposure period. Sculpins avoided only the high concentration of WAF, but avoided all concentrations of CEWAF and Corexit. Exposure to WAF, CEWAF and Corexit altered several behaviours including those associated with swimming and feeding. The studies here provide comprehensive data on the potential impacts of dilbit and dispersants on teleosts and will aid in the development of risk assessment plans for managing marine organisms in the event of potential dilbit spills in this and other coastal ecosystems.

**WP225 Mixture toxicity of true boiling point distilled fractions of Iranian Heavy Crude oil**

*S. LEE, Korea University; J. Kwon, Korea University / Division of Environmental Science and Ecological Engineering*

Marine oil spills are some of the most serious environmental problems worldwide as the oil-spill residues cause adverse ecological effects. Crude oil is a complex mixture composed of many components including hydrophobic hydrocarbons that are known to accumulate in organisms and to cause toxicity. It is acknowledged that the short-term toxicity of aromatic hydrocarbon mixtures, which are thought to be the main toxic components in oil residues, is explained by the concentration-addition model. However, only limited number of chemicals from oil mixtures was studied to evaluate whether the concentration-addition model is a good mixture toxicity model for short-term ecotoxicological endpoints. In this study, the luminescence inhibition of *Aliivibrio fischeri* was evaluated using true boiling point (TBP) distilled fractions of Iranian Heavy Crude oil (IHC) and mixtures composed of those fractions. Thirty-one TBP distilled fractions of IHC were obtained at TBP from 70 to 400 ?. The water accommodated fractions of 31 distilled fractions and 50 mixtures composed of 3 randomly selected distilled fractions were prepared, and the luminescence inhibition of *A. fischeri* by them was evaluated. From dose-response curves of 31 distilled fractions, the toxicity of 50 random mixtures was predicted by the concentration-addition model and the response-addition model. There were no significant differences in results predicted by the two models, and the experimental results were well described by the concentration-addition model for most of mixtures. All experimental toxic units (TUs) of random mixtures were within the range of ±50% from the predicted TUs using the concentration-addition model and TUs of seven mixtures deviated more than ±30% from predicted, although the experimental TUs of random mixtures were mostly lower than predicted. The weighted sum of TU of 31 TBP distilled fraction was 3.47, which is close to the TU 4.31 of the whole IHC WAF. This indicates that there are no significant interactions between constituents of oil-mixtures in luminescence inhibition of *A. fischeri*, and it is expected that the concentration-addition model could be used for the prediction of luminescence inhibition, a widely used short-term ecotoxicity endpoint, by various mixtures of crude oils.

**WP226 Establishing baseline biomarker levels in commercially important demersal fishes**

*M. Gagnon, Curtin University / School of Molecular and Life Sciences*

The Browse Basin off Western Australia is an area of significant oil and gas exploration and extraction. Large extents of the Browse Basin are practically undisturbed due to the remoteness of the area where exploration and extraction takes place, with only a few small scale commercial fisheries operating in the area. In order to fully predict and manage the impacts of a hydrocarbon spill on fisheries resources, the capacity to detect the exposure to and effect of point sources of hydrocarbons is required. The objective of this study was to establish baseline data for commercially important demersal fishes for which effects of hydrocarbons could be evaluated in the event of an oil spill. More precisely, the study focussed on baseline physiological and biochemical markers of fish health which can establish recent exposure to petroleum hydrocarbons, and/or induced health effects following exposure. Complementary chemical quantification of petroleum hydrocarbons in water, sediments and fish flesh were conducted at all nine sampling sites. The commercially important species goldband snapper (*Pristipomoides multidens*) and red emperor (*Lutjanus sebae*) were targeted using commercial fish traps. Within a species, some inter-site differences were identified in biochemical marker levels which might be associated with different water temperatures, food supply or other site-specific conditions. These variations are not indicative of good or ill health status in fish but rather, represent baseline levels at each sampling locations to which future investigations can refer to. A chemical characterisation of the surface water, water column, bottom sediments and fish fillets was undertaken to complement physiological and biochemical assessments of fish. While PAHs were detected in all environmental compartments, the levels at which they were detected were considered as background environmental levels. Specifically, the chemical characterisation did not provide evidence of the presence of petroleum hydrocarbons at any of the study sites that would indicate anthropogenic or natural sources of hydrocarbons. Hence the levels of biomarkers reported here at each site are considered an appropriate baseline of non-exposed fish.

## Modeling and Data Analysis Tools to Predict the Fate and Transport of Pesticides in the Environment

### WP227 Developing a selection procedure for meteorological data used by regulatory AERMOD modeling of pesticide applications in California

*J. Tao, California Department of Pesticide Regulation*

We developed a procedure to select a set of 5–year meteorological data as the worst-case scenario data for regulatory modeling of pesticide uses. We analyzed the relationship between the 95$^{th}$ percentile maximum concentrations estimated by AERMOD and the percentages of low wind speed (LWS, 0.5 – 2 m/s) in the meteorological data used for the modeling. The results of statistical analysis showed that they were positively correlated within various distances to different types of emission sources. In addition, the LWS percentages of 1-year data at a station could be used to predict the LWS percentages of 5-year data at the same station. Based on these results, our procedure begins with the evaluation of 1-year data quality and LWS percentages for all the available stations in areas with high use of a concerned pesticide. Five – year meteorological data are then processed for the top 5 or top 20% of stations with the highest LWS percentages to perform AERMOD modeling. Finally, the air concentration estimates are compared to determine the worst-case scenario data. This procedure provided a strategic plan for the selection of meteorological data. We applied the procedure in a case study of sulfuryl fluoride structural fumigation of residential houses and determined that 5-year (2011 – 2015) data of station WBAN 93134 is the worst-case scenario meteorological data.

### WP228 Using SWAT Model to Assess Pesticide Runoff from Central California Coastal Watershed

*Y. Xie, California Department of Pesticide Regulation; X. Zhang, California Department of Pesticide Regulation / Environmental Monitoring; Y. Luo, California Department of Pesticide Regulation*

The California Department of Pesticide Regulation's Surface Water Protection Program (DPR/SWPP) relies on modeling tools for pesticide registration evaluation and post-use risk characterization. This study aims to develop a modeling approach that links pesticide use and the associated risks in aquatic ecosystems, or "use-based modeling." DPR's Pesticide Use Reporting (PUR) database, which reports agricultural uses at section level (1 × 1 mile) and urban uses at county level, is used to derive pesticide use information. The Soil and Water Assessment Tool (SWAT) is used to assess the temporal-spatial variation in pesticide runoff, loadings, and in-stream concentrations in the Central California Coastal Watershed. A whole range of components, including land use, soil property, slope, meteorology, pesticide application and drift, crop growth, water management, in-stream processes are considered to simulate various physical processes occurring in the watershed, and predict fate and transport of pesticides in the system. The modeling approach developed by the study will be used to identify hotspots and critical source areas of pesticide contaminates in surface waters, assess the efficiency of regulation over time and space, and evaluate the effectiveness of management practices in mitigating pesticides in the watershed.

### WP229 Predicting the Effects of Plant Growth Stage and Species on the Volatilization of Pesticides from Agricultural Fields after Application

*M.R. Taylor, University of Otago / Chemistry*

Pesticides are an important tool in modern crop management to ensure high quality and high yield food production. However, pesticide volatilization from agricultural fields can have a significant impact on nontarget, sensitive ecosystems, and can result in a loss of revenue for farmers. We developed and validated a model, based on multiphase partitioning, that describes pesticide volatilization loss from a planted agricultural field and predicts 24-h cumulative percentage volatilization ($CPV_{24h}$) losses. The model allows the user to adjust the chemical-physical properties of the pesticide, species-specific plant surface chemistry, plant size, soil type and climatic conditions. A general equation for plant-air ($K_{plant\text{-}air}$) partition coefficients was generated and implemented in the model to describe the plant-surface chemistry interactions with pesticides. The model was used to address questions about whether pesticides tended to volatilize more from plants or soil, and how plant species and growth stage affect the amount of pesticide lost to the atmosphere. Results are displayed on chemical space diagrams for sets of hypothetical $K_{plant\text{-}air}$, $K_{soil\text{-}air}$ and $K_{water\text{-}air}$ combinations under different scenarios. The $CPV_{24h}$ increased with increasing temperature, foliar intercept fraction and windspeed and with decreasing plant size. We found that pesticides tended to volatilize more from plants than soil. $CPV_{24h}$ was highly varied between plant growth stage but was less varied between plant species. The model was then compared to current screening techniques employed by the EU and the USEPA for the risk assessment of pesticides. Current screening techniques use vapor pressure as an indicator of the risk of pesticide exposure in the atmosphere. However, $CPV_{24h}$ had no correlation with vapor pressure as this does not account for the multiphase interaction that occur in the real environment. The current techniques tended to overestimate the volatilization potential of high-vapor pressure pesticides, which can lead to a number of pesticide undergoing unnecessary screening and testing. Our model is therefore a promising new screening tool for pesticide volatilization from an agricultural field.

### WP230 A data-driven approach for prediction of pesticide dissipation half-lives in plants

*F. Gao, S. Boyd, Michigan State University / Department of Plant, Soil and Microbial Sciences; E. Zhao, Beijing Academy of Agriculture and Forestry Sciences / Institute of Plant and Environment Protection*

Pesticides are widely used to protect crops against various harmful pests in modern agricultural production. However, residues of pesticides in plants such as fruits and vegetables can potentially cause harm to humans and animals that consumed the plants, and has been a great concern in risk assessment. The dissipation process of pesticides in plants is one of the key studies during pesticide risk assessment. The half-lives of pesticide are important for estimation of pesticide concentrations found in plants at harvest time. Since the dissipation of pesticides from plants are related to multiple factors such as pesticide properties, surrounding environments and plant types, the prediction of pesticide dissipation half-lives has been a challenge and thus are heavily relied on experiments. But the experiments on dissipation half-life studies are limited compared with the large amount of pesticide-plant combinations. Prediction models would be useful for assessing all possible pesticide−plant combinations based on the available data. Since the processes of dissipation are not fully understood, in this study, we applied a data-drive approach using artificial neural network models to predict the dissipation half-lives. The chemical structures of pesticides were regarded as molecule graphs and unique molecule features were generated based on the random walk over the graph. To test the reliability of our feature extraction methods, we predicted the octanol-water coefficient($k_{ow}$) of pesticides which should be only related to the structures. Then these pesticide features were combined with other features (i.e. plant types, compartment parts) to form new features and fed into an artificial neural network to predict the Log(Half-life). Despite that very few knowledge of surrounding environments was available, our model tried to make the predictions based on limited information. First, we removed irrelevant data points in current datasets and then collected 100 more data points published in recent three years. Secondly, we further analyzed the structures of pesticides in the datasets and discussed its relation to dissipation half-lives. Finally, with 70% data point as training, 10% as validation and 20% as test, our model achieved state of art prediction results with mean absolute error($MAE_{log}$) 0.60. The results indicated that our deep neural network models can be successfully used for the prediction of pesticide half-lives in plants.

**WP231 Identification of the most influential watershed characteristics for pyrethroid pollution in stream sediments in California**

*D. Wang, R. Budd, C. DeMars, California Department of Pesticide Regulation; B.M. Phillips, B.S. Anderson, University of California, Davis / Environmental Toxicology; N. Singhasemanon, K. Goh, California Department of Pesticide Regulation*

Pyrethroids are a group of insecticides under intensive investigation in California because of their high use and high toxicity to aquatic invertebrates. This group of pesticides tends to have a high affinity for soil and sediment particulate matter. Their fate and transport in the aquatic system are largely associated with the movement of sediments and appear to be greatly influenced by the hydrological, geomorphological and anthropogenic characteristics of the contributing watershed. This study develops a statistical assessment procedure to investigate the link between the watershed characteristics and pyrethroid pollution using the pyrethroid concentrations in stream sediments that were quantified by the California State Water Resources Control Board's Stream Pollution Trends (SPoT) Program. Due to complex interactions among those watershed characteristics and possible non-linear relationship between the characteristics and the pyrethroid concentrations, alternative statistical methods such as partial least square regression and random forest models are considered. In addition, several variable importance ranking methods are explored in order to reach a robust conclusion. The most influential characteristics identified in this study can be used to build mechanistic models and guide the design of future monitoring efforts.

**WP232 Object-to-Mouth Exposure of Residents to Pesticides: What Isn't in the USEPA SOP**

*S. Slade, Blankinship Associates Inc*

The USEPA Standard Operating Procedures for Residential Pesticide Exposure (SOP) (2012) addresses non-occupational exposure to residentially applied pesticides through various routes of exposure. Of the exposure pathways discussed in the SOP, the methods for evaluating incidental ingestion of residues by a child mouthing an object previously sprayed with pesticide are limited. Unlike assessing hand-to-mouth transfer of pesticide residues, the SOP as published does not consider environmental degradation on common lawn objects such as tire swings, toys, and tables. The equation for non-dietary ingestion of pesticide residues on lawn objects would be improved by including a degradation factor in a manner consistent with hand-to-mouth assessment methodology. In this presentation, approaches for modeling dissipation of pesticides on lawn objects will be presented, with an emphasis on the strengths and limitations of each technique.

**WP233 Occurrence and distribution of pesticides in surface waters of California**

*X. Zhang, California Department of Pesticide Regulation / Environmental Monitoring; Y. Luo, N. Singhasemanon, Y. Xie, California Department of Pesticide Regulation*

For decades, state and federal agencies, as well as research institutions in California, have been collecting water and sediment samples for the purpose of pesticide analysis. A wealth of monitoring data has been generated and stored in the California Department of Pesticide Regulation's (CDPR) Surface Water Database (SURF). This study aims to characterize the overall occurrence and distribution of pesticides in the surface waters of California. Various statistical learning methods and GIS tools are used to assess spatial and temporal trends of pesticides in the surface water. Important factors associated with the detections of pesticides will be identified. The results generated by this study will provide an indication of California's aquatic ecosystem health, as defined by relative risks of pesticide active ingredients and degradates to sensitive aquatic species. Moreover, the results will serve to guide future monitoring efforts in California.

**WP234 Buffer Zone Determination Procedures used by the California Department of Pesticide Regulation's Air Program**

*K. Heal, A. Tuli, K. Alstad, M. Kandelous, California Department of Pesticide Regulations / Environmental Monitoring*

A variety of computer simulation models are used by the Air Program at the California Department of Pesticide Regulations (CDPR) to determine buffer zones during agricultural pesticide applications. A buffer zone is described as an area that surrounds a pesticide application block in which certain activities are restricted for a specified period of time to protect human health and safety from existing or potential adverse effects associated with a pesticide application. The models currently used by CDPR's Air Program to determine buffer zones are Agricultural spray Drift model (AgDrift), Industrial Source Complex Short Term Version 3 (ISCST3), and American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD). AgDrift is a unique dispersion model that combines Lagrangian trajectory algorithms which characterize the pathway of various sized droplets, with Gaussian deposition algorithms which summarizes all non-evaporated droplets hitting the ground. AgDrift has the capability to estimate downwind deposition of spray drift from agricultural applications and off-site deposition of liquid droplets. ISCST3 and AERMOD are both steady-state Gaussian plume models that can be used to estimate off-site air concentrations associated with pesticide applications. ISCST3 was designed to support the EPA's regulatory modeling programs, and has been used by CDPR as a regulatory tool for air dispersion modeling to develop buffer zones since 1991. In contrast to ISCST3, AERMOD allows for advanced plume dispersion simulation by accounting for boundary layer turbulence and scaling concepts leading to superior performance over previous air dispersion models. As of December 9, 2006, AERMOD replaced ISCST3 as the USEPA recommended dispersion model, and has been recently adopted by CDPR's Air Program. This poster intends to present and explain the various modeling procedures employed by the Air Program for buffer zone determination. Simplified examples will demonstrate each of these modeling approaches.

**WP235 Potential environmental risks associated with pesticide inert ingredients in California**

*M. Grieneisen, R. Wang, C. Demars, University of California, Davis; M. Zhang, UC Davis / Land, Air and Water Resources*

California's Pesticide Use Report (PUR) database, queried with the PURwebGIS tool (purwebgis.ucdavis.edu), documents 343 million lbs of pesticide products used in 2015, including 191 million lbs (56%) of active ingredients (AI). The remaining 152 million lbs (44%) are termed "inert ingredients" (inerts), a designation referring only to their lack of specific pesticidal properties and not to any potential risks. The extensive literature on environmental risks of AIs contrasts with very few studies on potential risks of inerts. Pesticide product MSDS give partial listings of inert ingredients. A survey of MSDS for ~1,300 products, comprising >95% of all lbs of product usage in PUR from 2011-2015, revealed hundreds of different pesticide inerts and their formulation proportions. We conducted a full PUR query of inert usage in California for 2011-2015, and analyzed inert usage data in light of potential environmental risks. One interesting group of chemically-related inerts are "Solvent naphtha (petroleum), heavy/light aromatic" (CAS: 64742-94-5 & 64742-95-6) and their C7-C12 aromatic hydrocarbon components, including the carcinogen naphthalene. They are neurotoxic to vertebrates, with aquatic $LC_{50}/EC_{50}$ values of 1-10 ppm for *Daphnia* and various algae, and were present in over 150 different products with 59 different AIs from 2011-2015. In 2015, they accounted for ~3 million lbs of usage and 11.3 million acres treated statewide, including many different crops throughout the state and the growing season, including the rainy season. This study surveys the usage of these "Solvent naphtha" inerts in the Sacramento River watershed (~300,000 lbs used in 2015) since 2011. After input of relevant physico-chemical properties (Koc, half-life, etc.), SWAT analysis was used to simulate their expected environmental fate according to field applications, focusing on potential loading to surface water sources. The results will demonstrate, for the first time, the environmental fate and potential environmental risk assessment of pesticide inert ingredients, and highlight the importance of including potentially high-risk inerts, along with AIs, in environmental monitoring programs.

## Effective Science Communication: Case Studies and Lessons Learned

### WP236 Applying a Translational Science Framework in Environmental Toxicology

*P.K. Sibley, University of Guelph / School of Environmental Sciences*

The problem formulation stage of ecological risk assessment has long identified the importance of broad engagement of scientists, stakeholders and decision-makers in assessing and managing risks associated with environmental problems but, in practice, mutual and productive participation is often lacking. In some fields, such as medicine and ecology, recognition of the need for more inclusive engagement has led to the emergence of translational science, an approach in which scientists, stakeholders, and decision-makers work collaboratively to facilitate the development of actionable, decision-relevant science. The underlying framework is based on the incorporation of sound science, socio-economic conditions, and political and public perspectives with the goal of promoting more inclusive decision-making ideally leading to improved policy formation and more effective management practices. While sharing many similarities to the traditional ecological risk assessment framework, it differs in the that it is based on participation of, and input from, all stakeholders at all points and in the application of emerging tools, such as scenario analysis and bow-tie risk assessment, that themselves incorporate collaborative approaches to problem solving and risk identification. In this presentation, I will introduce the concept of translational science, presenting a framework in the context of environmental toxicology; identify similarities and differences from the more familiar ecological risk assessment framework; and provide examples of its application using examples drawn from a scenario analysis exercise conducted to assess contaminants in the Great Lakes and hypothetical applications based on bow-tie risk assessment.

### WP237 Doing Science with a Marketing Plan: Developing the Rapid Benefit Indicators Approach

*W.J. Berry, USEPA / Atlantic Ecology Division / ORD / NHEERL; C. Ojo, NY State Department of Environmental Conservation; M. Mazzotta, USEPA / Atlantic Ecology Division; J. Bousquin, K. Mulvaney, D. Martin, R. McKinney, USEPA*

Many scientists work diligently to produce tools and resources that can be used to address real world problems. However, a disconnect often occurs between the creation of these scientific outputs and their use by intended stakeholders. Some reasons for this disconnect include limited involvement of users throughout the development of new products and a lack of marketing effort. Several approaches are currently being used by scientists and government agencies to address this problem, including Structured Decision Making and Translational Science. These approaches stress the importance of working with stakeholders throughout the entire process of developing a science product, from problem formulation, through initial planning, all the way to user support of the product. Scientists are often unfamiliar with or untrained in the concept of "marketing" their research products, but it is something that is vital to getting their work into the hands of those who can use them. We used a marketing plan based on the principle of the 4 Ps+1 (product, promotion, price, place + partnerships), during the development of the Rapid Benefit Indicators (RBI) approach, a resource created to help stakeholders assess the societal benefits of ecological restoration using non-monetary indicators. The RBI grew out of stakeholder discussions around the need for a user-friendly set of tools to help make decisions about what sites to target for marsh restoration. We worked with stakeholders through the entire process, from initial design to the development of a web page, a manual, an Excel-based tool, and a GIS-based tool. The marketing plan helped us to target stakeholders for initial discussions, reminded us to keep in touch with stakeholders through the process, and to get the word out to potential users when the product was finished. The approach worked, as evidenced by the fact that in the first year we had over 1,500 page views, over 400 downloads of the Excel checklist tool, and over 300 downloads of the manual. The RBI is also being hosted on several tool compendium web sites, and has been presented at a number of conferences and meetings. In the end it does not matter exactly what approach you use to market your products. What matters is that you have a plan to involve your stakeholders in the development of your products, from start to finish.

## Systems Approaches

### WP238 Sustainability of Struvite Precipitation Systems in Wastewater Treatment

*M. Sena, A. Hicks, University of Wisconsin – Madison / Civil and Environmental Engineering*

Current use rates of phosphorus have created concern for the sustainability of global phosphate reserves, and research has begun focusing on ways to recover and reuse phosphorus. Wastewater has gained appeal as a viable resource for phosphorus recovery, and the precipitation of magnesium ammonium phosphate ($NH_4MgPO_4$ $6H_2O$), or struvite, has emerged as viable technology. The intention of this technology is twofold, to prevent unwanted precipitation of struvite in pipes and on equipment in wastewater treatment plants, and to recover a valuable phosphorus product that can offset conventional fertilizer production. This research focuses on evaluating the environmental impact of struvite precipitation systems through the comparison of life cycle assessment studies. Understanding how struvite precipitation systems fit within the context of wastewater treatment, and what added or reduced environmental impacts they bring provides an opportunity to assess the technology as a whole. Literature shows two main schemes of struvite precipitation in wastewater treatment, from a urine source separated stream, or on a side stream within a conventional wastewater plant. Most studies show the greatest contribution to impacts coming from additional energy or chemical requirements. However, specific improvement or decline in environmental impacts depends on the characteristics of the particular system and environment analyzed in addition to boundary parameters such as the inclusion or exclusion of infrastructure construction and an offset of conventional fertilizer.

### WP239 Upcycling Waste to Create a Better Battery Anode using Life Cycle Assessment

*A. Hicks, University of Wisconsin, Madison / Civil and Environmental Engineering*

Increased battery storage is necessary as society shifts from fossil fuels to renewable electricity sources. However, increased battery usage comes with its own set of environmental impacts. Alternative anode materials for batteries, instead of utilizing battery grade graphite, have been a recent area of research. This work presents two synthesis processes for generate battery grade graphitic anode material from waste packing peanuts. Two synthesis processes are investigated, one using an inert gas environment and the other using a vacuum, to generate graphitic anode material, and their relative environmental impacts of quantified utilizing life cycle assessment. Life cycle assessment is a systematic tool for determining the environmental impact of a product or process throughout its lifetime. Often when waste products are utilized, such in the case of plastics, the resulting end product is inferior in some aspects compared to a product generated from virgin feedstocks. In this instance, however, the packing peanut derived graphitic anode material performed better in charge recharge cycles than the conventional battery grade graphite. This is due to the disordered nature of the derived graphitic material, compared to the ordered nature of graphite. This suggests, that in this instance the anode material produced from a waste product is actually superior to the virgin standard. With respect to environmental impact, in the case of the inert gas derived anode material, the greatest contribution was due to the quantity of gas utilized. Whereas for the vacuum derived material, it was due to the electricity consumption, and in turn heavily influenced by the source of the electricity. This work suggests that in some instances of utilizing waste materials that the functionality may be increased compared to using virgin materials. Life cycle assessment was utilized to evaluate the environmental hotspots of the synthesis processes utilized for the graphitic anode materials.

## Policy, Management and Communication

**WP240 A comparative review and analysis of tentative ecological quality objectives (EcoQOs) for protection of marine environments in Korea and China**

*J. Khim, Seoul National University / School of Earth and Environmental Sciences; S. Hong, Chungnam National University / Department of Ocean Environmental Sciences; Y. Seojoon, Seoul National University; J. Nam, Korea Maritime Institute / Marine Policy Research Division; J. Ryu, Anyang University / Department of Marine Biotechnology; S. Kang, NOWPAP MERRAC & Korea Research Institute of Ships and Ocean Engineering*

Ecological quality objectives (EcoQOs), as tools for implementing ecosystem approach, have long been acknowledged to protect the marine ecosystems and fisheries in regional seas through joint efforts by surrounding countries over the past decade. The present review analyzed the best available meta-data relating to the five ecosystem elements that were recently proposed by the Northwest Pacific Action Plan to evaluate the current status of coastal ecosystem health in marine environment of the Yellow Sea. We suggested the six tentative EcoQOs among five ecological quality elements including: 1) biological and habitat diversity; 2) invasive species; 3) eutrophication; 4) pollutants; and 5) marine litters. Environmental status were assessed by comparison with the world average values, existing environmental standards, or reported values of other regional seas. Results of analysis revealed that among the six tentative EcoQOs, two target objectives to marine biodiversity and concentrations of nutrients (viz., DIN and DIP) were met towards good environmental status. Whilst, three EcoQOs relating to hypoxia and red-tide, pollutants (persistent toxic substances and metals), and marine litters (including microplastics) did not meet and one relating to invasive species could not be judged due to insufficient data sets. The biggest weak point for developing suitable EcoQOs and assessing status of ecosystem health could be insufficient meta-data sets available and/or differences in chemical analyses and biological identification methods between the countries. Thus, the cooperation of neighboring countries, viz., Korea and China for the Yellow Sea, is necessary for the ecosystem based management of our regional sea in the future. Overall, this first time review for the target tentative EcoQOs in the Yellow Sea regions encompassing coasts of Korea and China would be provide better understanding of the current environmental status and ecosystem health.

**WP241 Forecasting the international process of validating New Approach Methodologies (NAMs) in ecotoxicology: Results from a Policy Delphi study**

*M. Mondou, G. Hickey, McGill University / Macdonald Campus / Natural Resource Sciences; S. Maguire, G. Pain, McGill University / Desautels Faculty of Management; D. Crump, Environment and Climate Change Canada / National Wildlife Research Centre; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre; N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences*

Validating New Approach Methodologies (NAMs) holds the promise of overcoming the limitations with current approaches in regulatory ecotoxicity testing. As time, cost and ethical pressures are mounting towards changing regulatory practices centered on whole animal studies (so-called "kill them, and count them" studies), the global regulatory ecotoxicology community is struggling to find the right way to leverage the desirable properties of NAMs in an appropriate way in their daily work duties. What are the future scenario options for validating the use of NAMs? How desirable and feasible are these options for the future? How much do they – or do not – reflect a consensus in the global regulatory ecotoxicology community? What are the foreseeable impacts and consequences of these options? These are the questions that this poster will address. Building on our previous survey and documentary research, we will elicit the opinion of the world's top NAM experts to provide innovative answers to these challenging problems. We will do so through a Policy Delphi exercise. A Delphi is a group communication process that solicits judgments through sequential questioning interspersed with summaries and feedback derived from previous responses. The Policy Delphi offers a virtual and anonymous, deliberative and analytic participatory group process designed to: 1) integrate the knowledge, values and experience of a group of people representing different areas of expertise; 2) advance social and organizational learning; 3) map consensus and dissent; while 4) minimizing social group dynamics during deliberation. The Delphi is well suited to processes that require input from multiple, different, and often conflicting points-of-view since it allows participants to respond on their own time, to share their opinions without reputational risk, and to contradict others who may occupy a more powerful social position. The steps generally involved in a policy Delphi are: 1) the formulation of the issues; 2) exposing the options; 3) determining initial positions on the issues; 4) exploring and obtaining the reasons for disagreements; 5) evaluating the underlying reasons; and 6) re-evaluating the options. This Delphi exercise will offer opportunities for social learning, which is crucial for effective rational deliberation. It may also uncover disagreements and facilitate the examination of complex problems.

**WP242 QSAR Validation for Pesticide Registration in South Korea**

*J. Ock, Seoul National University of Science and Technology; K. Kim, Seoul National University of Science and Technology / Environmental Engineering*

In South Korea, 3,066 pesticides including organic pesticides were listed under the Enforcement Decree of the Agrochemicals Control Act. Non-animal testing is recommended for toxicity test in chemical regulation, The Quantitative Structure-Activity Relationship (QSAR) models have been increasingly utilized to predict toxicity end-points by using physico-chemical properties (e.g. molecular structure) of chemicals of target.
To examine the applicability of QSAR into the prediction of fish acute toxicity of pesticides, the Ecological Structure Activity Relationships (ECOSAR, v2.0) providing various information of organic compounds, was used for predict 96h LC50, which compared with experimental LC50 values identified from National Chemicals Information System (NCIS). Our results suggest that QSAR could be the alternative tool of toxicity testing with animal model QSAR in pesticide registration. Further toxic end-points should be assessed to increase the applicability and usage on registration procedure of chemicals.

**WP243 Sustainability Index: A KPI for Industry**

H. Plugge, *Verisk 3E*

Sustainability is often described as an essential pillar of environmental stewardship. How can we track how sustainable an enterprise is? For chemical manufacturers and especially distributors and formulators, it can be a minefield of different definitions and methodologies. Here we have defined sustainability as optimizing risk, by first tackling the big risks followed by lesser risks. How does one go about defining let alone calculating “risk” for a chemical distributor with often thousands of products? Given that hazard and risk are often used interchangeable (they are not) one first needs to discuss hazard assessment: the art of defining a chemical as a hazard regardless of concentration (Hence 60 ppm formaldehyde in a pear is ignored while 30 ppm in shampoo is hazardous and banned- de facto regulation). Risk in its simplest form equals the product of hazard and exposure. The environment long has had Key Performance Indicators aka environmental standards or thresholds. Thus the presence of 2 mg/L of a metal is a KPI. Such KPI’s are always single media and single chemical based. How is a formulator with 15000 plus products (aka mixtures) to produce a KPI or Sustainability Index? Defining sustainability as optimizing risk allows one to provide an enterprise wide risk screening estimate. Given that this involves summing over thousands of mixtures, how does one go about calculating a single KPI for either health or environmental risk? First of all this will be a quantitative risk screening estimate with lots of simplifying assumptions. Exposure can be thought of as total inventory present i.e. the quantity of chemicals within an enterprise. Hazard is more tricky. Using our 3E GreenScore methodology one can calculate a hazard metric based on 26 parameters which is quantitative and dimensionless, thereby allowing summing of effects across chemicals. Risk = hazard X exposure summed across all chemicals in the inventory. A KPI can now be calculated as excess risk per facility or probably better as excess risk per unit of inventory e.g. risk/kkg. The optimum KPI ideally would be 1, so its proximity to 1 can be measured over time as sustainability and hence the KPI improves. Such KPI’s can be calculated for health and environmental hazard (it is not recommended they be combined as they tend to trend very differently.) It should be noted here that these KPIs can be used for optimizing risk and delineating sustainability using hazard based approaches.

**WP244 The predictive lead emissions of lead-acid batteries toward 2030 in China based on the lead life cycle and its metabolism**

S. Chen, *S. Li, Z. Lian, Beijing University of Technology / College of Environmental and Energy Engineering*

Lead-acid batteries (LABs), widely used batteries in cars and electric vehicles, have occupied a very important position in batteries industry for more than a decade. In this study, we analysed the lead metabolism in LABs industry systematically. We obtainedthe LABs production, lead demand of LABs, secondary lead production potential of LABs and lead emission of LABs before 2015 through literature collection in China. It wasfound that the LAB production increased dramatically before 2015. Then, we proposed three scenarios for LABs production: lead demand of LABs, secondary lead production potential of LABs and lead emission of LABs toward 2030. The results showed that the LABs production would continue to grow under the high scenario, reach a peak under thebaseline scenario and then decrease under the low scenario. As for thelead demand of LABs, it will goto a peak around 2020 under the high scenario and baseline scenario, then bereducedto 6.16 and 3.84 million tonnes toward 2030, andit will continue to decrease to 2.63 million tonnes toward 2030 under low scenario. The peak value of secondary lead production potential of spent LABs willbe 2 or 3 years later than the lead demand of LABs and it will continually reach the lead demand of LABs in the year. The total lead emission will reach peak in 2020 and then decrease and the total lead emission under the three scenarios will be 2.16, 1.67 and 1.36 Mt in 2020 and reducedto 1.67, 1.26 and 0.78 Mt toward 2030, respectively. *Keywords:*Leadacid batteries production, Lead demand, Secondary lead, Lead emission

**WP245 Verification of QSAR models for persistence and bioaccumulation of SVHCs**

J. Moon, *Seoul University of Science & Technology; J. Ra, Korea Institute of Industrial Technology; K. Kim, Seoul National University of Science and Technology / Environmental Engineering*

SVHCs (Substances of Very High Concern) regulated by the European Chemicals Agency include the substances classified as Carcinogenicity, Mutagenicity, toxicity for Reproduction (CMR) and persistence or bioaccumulation. The persistence and bioaccumulation of chemicals determined by experimental or non-tested methods are very important indicators related to chemical regulations. Among non-test methods, the Quantitative-Structure Activity Relationship (QSAR) model is a method of predicting physico-chemical properties or toxicity based on the structure of the chemical, and is also used to evaluate persistence and bioaccumulation. However, since QSAR is currently not fully validated, incorrect predictions of QSAR might lead to applicability limit. This study will validate and analyze the KWWIN, BIOWIN, BCFBAF, and HYDROWIN, which are used to predict the persistence and bioaccumulation of chemicals. The verification and analysis of the QSAR models will be performed by comparing the model predictions with the actual values. Target substances will be categorized as “SVHCs classified persistence or bioaccumulation” and “Substance not classified persistence or bioaccumulation” and will identify differences in accuracy and limitation between two groups. Additionally, differences will be identified depending on the structural properties of the chemical. Further studies are needed for various non-tested methods such as read-across, categorization as well as various QSAR models.

## Engineering, Remediation and Restoration

**WP246 A meta-proteomic study of polystyrene degradation by gut microbiota of *Tenebrio molitor* larvae**

A. Navlekar, *Texas Tech University; D.L. Carr, Texas Tech University / Biological Sciences*

In the last 50 years, there has been a rapid increase in plastic usage in almost every sphere of life. Polystyrene (PS) or Styrofoam, as it’s more commonly known, has been used in various products like cups and packing material and also as a raw material and solvent in the processing of polymers. Its uncontained production, constant daily usage and incorrect disposal have led to grave environmental problems including destruction of wildlife habitats and bioaccumulation in food chains. Until very recently, it was assumed that polystyrene was non-biodegradable. A study conducted in 2015 showed the ability of *Tenebrio molitor* larvae to degrade polystyrene; the ability was attributed to their gut microbiome (Yang et al., 2015). The researchers concluded that the degradation must occur due to secretion of enzymes by their gut micro-organisms. We recently completed a metagenomic study of polystyrene (PS) degradation by *Tenebrio molitor* (larvae of the Mealworm beetle) where we showed that the native gut microbial community of *Tenebrio* itself can degrade polystyrene without much change to the community composition or structure. To further elucidate the proteins involved in this degradation, we conducted a metaproteomic study of gut microbiota of *Tenebrio*. In this study we report on the metaproteomic diversity and identification of major protein groups that the gut microbiota of mealworms produced when fed with Styrofoam as their only food source and compared them to mealworms fed a normal bran diet. Proteins were extracted from the guts of *Tenebrio* larvae (standard diet vs. PS-fed only) using cytosolic and membrane protein extraction buffers. The extracted proteins were separated on the basis of pI and hydrophobicity using a Two-Dimensional Protein Fractionation instrument. Selected aliquots were then trypsonized and passed through a mass spectrometer with Orbitrap mass analyzer for identification by their mass-to-charge ratios. Results from this study contribute to understanding of the functionality of this mixed gut community that enables *Tenebrio* to degrade PS successfully. The broader impact of this study lies in determining microbial proteins with homological similarity to existing proteins, especially those that can be mass produced. The use of mass produced homological proteins/enzymes for plastic recycling, one of the most intractable problems of human society today, are expected deliverables from this study.

**WP247 Adsorption kinetics for the removal of dyes by millet and rice husk bio-waste materials in aqueous medium**

*A. Udeozor, Evangel University Akaeze Ebonyi State / Bio-chemistry; O. Mbonu, Federal Polytecnic Afikpo Uwana / Biochemestry*

Colouring materials that gives desirable colours to our everyday activities and commodities are called Dyes. Dyes can be Cationic (basic in nature), Anionic (acidic in nature) or Amphoteric (exhibiting both acidic and basic character). There is hardly any industry where dyes aren't required either for beautification or for protection ranging from Children's toys, Household appliances to fabrics. Due to the ubiquitous nature of dyes, they constitute environmental pollutants that pollute water bodies. This research investigates the removal of the dye, methyl red (MR) and methyl blue (MB) from aqueous environment using two biosorbent materials, namely, Millet and Rice Husk. These two selected biosorbents were studied under varying experimental conditions such as: effect of Contact time, Temperature, pH, Dye concentrations among others. The results of these experiments were modeled using standard Physical Chemistry Sorption Kinetic Isotherm Models. The result of these models shows that the two biodegradable locally available materials fitted some of these models like Pseudo first and Pseudo second orders, Langmuir and Freundlich isotherm. The calculated Sorption maximum capacities are 56.67% (2.67mg/g), for MilletHusk and 52.04% (2.57mg/g) for Rice Husk at 318K. It was observed that Sorption increases with increase in standard temperature in Kelvin for the two biosorbents studied. Various Isotherm models evaluated showed that the two Biosorbents have significant potentials as biodegradable sorbents for the removal of Methyl orange and Methyl blue colours from aqueous environments.

**WP248 Biodegradation and Final Solution Toxicity of Mature Fine Tailings from Oil Sands Processing in Fort McMurray, Canada**

*S.M. Harmon, E.J. Peck, University of South Carolina, Aiken / Biology and Geology; R.L. Brigmon, Savannah River National Laboratory*

Alberta Canada contains the third largest oil sand reserve in the world, producing about 2.3 million barrels of oil per day. Oil sands are a mixture of sand, clay, small amounts of water, and the viscous hydrocarbon bitumen. Mature Fine Tailings (MFTs) are the byproduct of oil sand refinement, as bitumen is separated from the sand and clay. MFTs contain many different chemicals and toxic material, such as naphthenic acids, which are potential endocrine disruptors, and polycyclic aromatic hydrocarbons, some of which are carcinogens. These contaminants are of major concern to the environment because of their toxicity and persistence. It has been found that the patented microbial consortium BioTiger™ (BT) has the ability to cometabolically biodegrade specific chemical components that are found in MFTs, including hexanoic acid and phenanthrene. The purpose of this project was to determine BT could successfully remediate the toxicity of MFTs collected from Fort McMurray, Canada. Test solutions were prepared by combining BT with MFTs in an aqueous solution. The BT/MFT sample was then split; half was immediately cooled to 4°C to slow/halt bacterial activity; and the other half was allowed to incubate for 7 days at room temperature. Acute toxicity tests were conducted on each solution with the freshwater organism, *Daphnia magna*. Results indicated that incubation with the BT significantly increased the toxicity of the MFT solution. Chelation with EDTA did not significantly reduce toxicity, indicating that dissolved metals were not the ultimate source of toxicity despite their high concentrations in the MFTs.

**WP249 Characterization of Sorption Mechanisms for Enhanced Microbial Remediation Processes of Uranium**

*V. Ibeanusi, Florida A&M University; G. Chen, FAMU-FSU College of Engineering; J. Hoyle-Gardner, A. Chauhan, C. Jagoe, H. Howard, Florida A&M University; J.C. Seaman, University of Georgia / Savannah River Ecology Laboratory*

Based on our batch experiments, microbial remediation studies that include *Bacillus spp*, and *Burkholderia* sp. may immobilize uranium transport by forming uranium-bacteria complex in the presence of phytate. Our current column studies were conducted to demonstrate that without the uranium-bacteria complex formation, uranium was able to be transported in the subsurface soil with through mediation of *Burkholderia* sp. Specifically, uranium transport was observed in three different scenarios: (1) uranium pre-deposited in the soil and then flushed with *Burkholderia* sp., (2) uranium and *Burkholderia* sp. mixture being introduced to the column, and (3) uranium and *Burkholderia* sp. being introduced at the same time but separately. Column transport experiments were conducted by acrylic columns with 3.0-cm ID ´ 10.0-cm length. The soil was packed in the column through $CO_2$ solvation to eliminate air pockets. For all above three scenarios of uranium introduction, 10 ml uranium at a concentration of 10 ppm was used. For *Burkholderia* sp. application, cell aliquote at a concentration of $10^8$ cells/ml was used. Studies with *Bacillus spp* and other competent bacterial strains will be demonstrated as well. We envision that the outcome of this study could provide a framework for: 1) long-term monitoring of U at DOE waste sites; 2) provide a tool for evaluation of natural attenuation-based processes; and 3) present research opportunities for enhanced attenuation approaches for radionuclide and heavy metals at DOE sites, and other uranium-contaminated sites

**WP250 Characterizing the Groundwater-Surface Water Interface Pathway at Hazardous Waste Sites using Two Pore Water Sampling Methods**

*R. Zajac, CH2M; J. Johnson, M. Fulkerson, B. Fishwild, A. Baseman, Jacobs*

The groundwater-surface water interface (GSI) is an important pathway to evaluate, as contaminated groundwater may discharge into surface water, and can impact aquatic ecological receptors. This case study compares the use of two different pore sampling methods to characterize pore water at hazardous waste sites. The well point method and push point method were used at two different sites, located in the Midwest and Southeast, to assess the GSI pathway. Each site presented a different objective and need for GSI data. At the Midwest site where the well point method was utilized, the objective was to delineate a VOC groundwater plume and conduct a screening-level ecological risk assessment for aquatic receptors. At the Southeast site, where the push point method was utilized, the objective was to assess the potential for the discharge of VOC-contaminated groundwater into the creek, which also supported an evaluation of an existing pump and treat groundwater treatment system upgradient of the creek. This case study presents the data needs to evaluate potentially complete GSI pathways, information on each sampling method, and demonstration on how the data collected at each site was used to aid in the investigation and decision-making process.

**WP251 Chemistry's role in understanding and remediating a Superfund Site that's home to numerous abandoned mine and mill sites**

*E. Naylor, A. Hughes, Maul Foster & Alongi*

The East Fork Ninemile (EFNM) Basin, an approximately 3-mile-long watershed just outside Wallace, Idaho, and within the Bunker Hill Superfund Site, is burdened by numerous abandoned mine and mill sites. The basin contains over a million cubic yards of mine waste laden with lead, zinc, and cadmium, found primarily in consolidated mine waste piles adjacent to EFNM Creek. Physical and chemical processes affecting the mine waste piles have resulted in contamination of the watershed's native soils, groundwater, surface water, and sediments, posing a risk to human as well as terrestrial and aquatic ecological receptors. A Record of Decision issued by the USEPA requires remedial action at several sites in the EFNM Basin. Iterative investigative work has been conducted throughout the EFNM Basin to create conceptual site models that are used to direct and prioritize site remedial actions. Predesign investigations are conducted at mine waste piles to determine the nature and extent of contaminants of concern in all media. Subsequent remedial design investigations fill environmental data gaps and provide designers with geochemical, geotechnical, and agronomic parameters at each pile. Recently, an area-wide investigation was designed and implemented to establish how/where groundwater and surface water may be loading metals to the EFNM Creek from known sources, identify possible unknown sources, and provide baseline to evaluate the effectiveness of future remedial activities. The findings of ongoing predesign and remedial design investigations have resulted in the removal of 650,000 cubic yards of mine waste and impacted native soils and remedy effectiveness monitoring has begun in some of the removal areas. The area-wide surface and groundwater investigation conducted has identified a significant nonpoint source of metals loading into the EFNM Creek that was previously unknown/unanticipated and conversely, shown that a large mine waste rock pile is not a significant source of loading. This discovery has helped complete the basin-wide conceptual site model. These findings will require additional investigative work, the results of which will guide future remedial actions and remedy effectiveness monitoring in the EFNM Basin.

**WP252 Development of passive sampling approach for assessing atmospheric Polychlorinated biphenyls (PCBs)**

*A. Aribidara, D.D. Reible, Texas Tech University / Civil and Environmental Engineering; C. Price, D. Acevedo-Mackey, US Army Engineer Research and Development Center*

Volatile losses of hydrophobic organic contaminants (HOCs) such as polychlorinated biphenyls (PCBs) during placement and disposal of contaminated sediments are a continual cause of concern to confined disposal facilities (CDFs) and its environs. Presently, conventional method such as the high-volume sampler is employed to constantly monitor the level of atmospheric HOCs surrounding the CDFs. This method of sampling is labor intensive, costly and incapable of providing long term averaged concentration of contaminants. To address these limitations, passive sampling approach is being explored as a potential air sampler. Preliminary laboratory time series experiments were conducted to evaluate polydimethylsiloxane (PDMS ~34 µm) and Polyoxymethylene (POM-76 µm) as passive air samplers for HOCs, and to assess the potential of the chosen air sampler to contaminated sediment collected from Indiana Harbor and Canal, Confined Disposal Facility (IHC- CDF). The laboratory evaluation was conducted by exposing polymeric passive samplers in the airspace over an aqueous solution to which was introduced a mix of PCBs or to a slurry of sediment collected from the IHC-CDF. Uptake on the samplers was determined by high-performance liquid chromatography (HPLC) and gas chromatography, triple quadrupole Mass spectrometer (GC-TQ). The results suggest that POM gives a longer exposure time averaged concentration compared to PDMS, and that POM is generally not responsive to short term losses prevalent in the system. Analysis of experiments with slurries using sediment from the IHC-CDF showed a consistent uptake of PCBs on POM and their POM-air partition coefficients measured ranged from 6.35 to 7.91 log units. The partition coefficients measured differs from literature values by 0.1-0.4 log units and suggests an underestimation of the partition coefficients at 28 days especially for higher molecular weights PCBs. The method was then tested with preliminary application of POM deployed at 10 stations around the IHC-CDF over 42 days to measure air concentration of PCBs. The results show generally low air concentrations around the site with total PCBs below 10 ng/m$^3$. The passive sampler measured air concentrations of specific congeners that were very similar in magnitude to those measured by high volume air sampling at the same locations. In summary, passive sampling exhibits the potential to be an excellent alternative means of measuring PCB air concentrations around the CDFs.

**WP253 Effect of Laser Stimulation on Plant Growth and Uptake of Cadmium in Indian Mustard (*Brassica napus*)**

*B. Rimal, Texas Tech University / Biological Sciences*

*Brassica napus (*Indian Mustard) is often found as a primary colonizer of disturbed lands including mine tailings, and is reported to accumulate high concentrations of Cadmium while also producing high concentrations of metal chelators like succinic acids at its root zone. We conducted an in-vitro experiment to observe the germination, biomass accumulation and cadmium uptake potential of laser stimulated and non-stimulated Indian mustard grown in half MS-medium for two weeks. Cadmium spiked medium were maintained at 20 ppm and 40 ppm cadmium chloride concentrations. 3 replicate bottles with 6 seeds for each treatment were maintained at 20° C, 16:8 light/dark cycle and 275 mmoles/m$^2$/s irradiance. Destructive sampling of the plants was done after 2 weeks for quantification of accumulated biomass and cadmium uptake at plant roots and shoots. No significant difference was observed in germination rate between laser stimulated and non-stimulated seeds grown in both cadmium spiked and non-spiked medium. Laser stimulated seeds grown in medium spiked with 20 ppm cadmium produced significantly higher root, shoot and total biomass . Laser stimulated seeds grown in medium spiked with 40 ppm cadmium produced significantly higher root biomass and laser stimulated seeds grown in medium with no cadmium contamination produced significantly higher total plant biomass and shoot biomass.

**WP254 Effectiveness and Optimization of Remedial Actions for Risk Management of Perchlorate-Impacted Groundwater**

*H.L. Govenor, Ensafe Inc. / Biological Systems Engineering; B. Mulhearn, A. Jacobs, B. Hamby, Ensafe Inc*

Historical operations at a former Navy facility near McGregor, Texas lead to perchlorate contamination in surface water (up to 5,600 ppb), groundwater (91,000 ppb), and springs (22,000 ppb) in a 750-acre watershed. To control contaminant migration off-site and limit surface water contamination from groundwater, Interim Stabilization Measures (ISM) and Institutional Controls (IC) were put in place. ICs included land use controls and a deed notice to limit property use to commercial/industrial (i.e., non-residential), establishment of a Plume Management Zone, and a deed notice to establish a landfill cap (Class II/III landfill). ISM include on-site treatment of impacted soils comprised of a lined soil treatment system with anaerobic landfarming with citric acid, nitrogen and phosphorus, and soda ash amendments. In addition, a pump and treat system was installed to eliminate the groundwater to surface water migration pathway and prevent continued offsite plume migration. In addition to the ISM, additional remedial actions were conducted at the southern end of the Plume Management Zone that included passive in situ biotrenches/biowalls and bioborings amended with mushroom compost, woodchips, and gravel mixed with emulsified vegetable oil. These treatments effectively reduced perchlorate concentrations in groundwater at the Site; as of 2018 the mass of perchlorate in groundwater has been reduced by 80% from 2000 mass calculations. This mass reduction, along with updated ecological hydrogeologic, and hydraulic studies is allowing the Navy to consider alternative remedial measures and optimization. The current optimization is focusing on a completely low cost passive in situ system designed to remediate a smaller, higher concentration on-site plume segment since off-site concentrations in both groundwater and surface water are below regulatory limits.

**WP255 Efficiency of Columbia Wetlands in Removing Pharmaceuticals and Personal Care Products from Treated Municipal Wastewater**

*M. Bayati, D. Vu, University of Missouri, Columbia / Center for Agroforestry; T. Ho, Cuu Long Delta Rice Research Institute; F. Wang, University of Missouri, Columbia; S. Huebotter, Columbia Regional Wastewater Treatment Plant; E. Inniss, R. Udawatta, S. Jose, University of Missouri, Columbia; C. Cuvellier, Columbia Regional Wastewater Treatment Plant; C. Lin, University of Missouri, Columbia*

Pharmaceuticals and personal care products (PPCPs) represent pollutants of emerging concern, originate from direct human disposal and other personal care use before disposal in the wastewater systems. Several classes of PPCPs that have endocrine disrupting activity such as fluoxetine (antidepressant), erythromycin (antibiotics), iopromide (X-ray contrast), estrone (estrogen), triclosan (antibacterial), and progesterone (endogenous steroid hormone) are persistent and frequently found in effluents from municipal and hospital wastewater treatment facilities. Endocrine disruptive PPCPs can adversely affect normal reproductive, behavioral, immune system, and neurological functions of aquatic organisms. Several studies indicated that conventional wastewater treatment plants (WWTPs) are not able to completely remove these kinds of micropollutants from wastewaters and they are consequently discharged into the aquatic environment. Constructed wetlands have been successfully used as a tertiary treatment process for removal of biological oxygen demand (BOD), total suspended solids (TSS), organic matter, nitrogen, and phosphate from domestic wastewater. However, there are studies showed the effectiveness and efficiency of this low-cost, environmentally friendly tertiary treatment process in the removal of the PPCPs. In this study, we conducted sampling sessions over a period of one year on Columbia wetlands (CWTs) and more than fifty PPCPs compounds in the inflow and outflow have been detected. High removal efficiencies were observed for estrone, azithromycin, tolfenamic acid, and diphenhydramine. From the present study, it can be concluded that Columbia wetlands may provide a complementary treatment option.

**WP256 Evaluation of different biological activities in monitoring of the effects of increasing concentration of petroleum in agricultural soil**

*C.O. Onwosi, University of Nigeria / Department of Microbiology; J.N. Odimba, V.C. Igbokwe, University of Nigeria, Nsukka / Department of Microbiology; C.J. Aneke, Enugu Sttate University of Science and Technology / Department of Biochemistry*

The resultant effects of the persistent contamination of the soil environment by organic pollutants are known to be deleterious to soil components and by extension, humans. Therefore, bioremediation monitoring is pertinent in ensuring the effective and efficient restoration of soil activities. In this study, soils polluted with varying concentrations of diesel (IC 1, IC 2, IC 3) at initial TPH concentrations of 14785.84 mg/kg, 23859.52 mg/kg and 42134.96 mg/kg, respectively, were bioremediated using rice husk as biostimulant. Different soil biological parameters namely soil enzyme activities (catalase and b-glucosidase), soil microbial biomass carbon (MBC), nitrogen (MBN) and phosphorus (MBP), soil microbial respiration as well as the soil phytotoxicity were used to monitor the bioremediation process. At the end of 56-day study, the degradation rate for IC 1, IC 2 and IC 3 were recorded at 99.1%, 98% and 97.6% respectively. The 1$^{st}$, 2$^{nd}$ and nth-order kinetic equations were used in determining the efficiency of the treatment for the increasing concentrations of diesel polluted soils. The results of 1$^{st}$ order kinetics for IC 1 ($k$= 0.6745 d$^{-1}$, $R^2$= 0.9388); IC 2 ($k$= 0.5738 d$^{-1}$, $R^2$= 0.9287); IC 3 ($k$= 0.6058 d$^{-1}$, $R^2$= 0.9626); 2$^{nd}$ order kinetics for IC 1 ($k$= 8.748×10$^{-5}$ d$^{-1}$, $R^2$= 0.8594); IC 2 ($k$= 4.301×10$^{-5}$ d$^{-1}$, $R^2$= 0.8457); IC 3 ($k$= 3.046×10$^{-5}$ d$^{-1}$, $R^2$= 0.9839); nth order kinetics for IC 1 ($R^2$= 0.9492, $k$= 4.472 d$^{-1}$, $n$= 0.7919); IC 2 ($R^2$= 0.9394, $k$= 6.239 d$^{-1}$, $n$= 0.7517); IC 3 ($R^2$= 0.9882, $k$= 0.0028 d$^{-1}$, $n$= 0.3082). From the results obtained, all biological activities for IC 1 except MBN were most responsive to the rice husk treatment than those of the IC 2 and IC 3. Improved plant growth was also observed in IC 1 and IC 2, as compared to IC 3, towards the end of the bioremediation study. These outcomes showed that the use of biological parameters is indispensible in monitoring the efficacy of a bioremediation process on contaminated soil.

**WP257 Groundwater-Surface Water Interface (GSI) Investigations used to Guide Risk Management Decisions**

*J.P. Johnson, F. Dillon, D. Boehnker, P. Weber, Jacobs; C. Smith, B. Chadwick, Coastal Monitoring Associates*

Historical investigations at an industrial facility in the Eastern United States identified elevated volatile organic compounds (VOCs) in site groundwater. Site-related groundwater data were evaluated to identify potential groundwater plume venting areas in the river adjacent to the facility where ecological receptors might be exposed at the groundwater-surface water interface (GSI). Multiple pore water investigations were conducted to identify potential VOC venting zones and determine if VOC concentrations in sediment pore water potentially pose unacceptable ecological risks to aquatic biota. Each investigation phase involved collection of pore water for VOC analysis using the Trident Probe, a direct-push, integrated conductivity/temperature sensor and GSI sampler. The first phase of the investigation included collection of pore water opposite areas of elevated onshore groundwater VOCs in 9 site remediation areas. The initial phase confirmed the presence of VOCs in pore water exceeding ecological screening values opposite 6 remediation areas. Subsequent investigations were designed to facilitate additional pore water characterization and delineation in identified venting zones. The Trident Probe data provided key information needed to refine the hydrogeological conceptual site model regarding the relationship of site groundwater with the GSI. Subsequently, the pore water data were used to evaluate potential ecological risks, support ongoing onshore site characterization activities, and to support ongoing risk management decisions. This presentation presents the Trident Probe methods employed, investigation findings, and how the data collected supported risk management decisions.

**WP258 Immobilized fruit and vegetable peels as effective biosorbents for removal of arsenic and heavy metals simultaneously from cocktail solution**

*R.J. Singh, University of Otago / Pharmacology and Toxicology; C.E. Martin, University of Otago / Geology; R.J. Rosengren, University of Otago / Department of Pharmacology Toxicology*

Contamination of arsenic and heavy metals in drinking water is a globally growing concern as these produce toxicity even at very low levels. Various methods for removal of such non-biodegradable toxins have been proposed, but are likely to be impractical in developing countries owing to their high costs. Biosorption is a cost-effective and convenient method that may be used for decontamination of water by incorporating waste products such as fruit and vegetable peel (FVP) produced in large quantities by food and beverage industries. The surfaces of these FVPs have certain functional groups that provide natural binding sites for the uptake of various ions from aqueous solution. The current study aims to study the potential of a few FVPs such as apple, banana, cucumber, kiwifruit, orange and potato peels as potential biosorbents for removing arsenic, cadmium, chromium, copper, mercury, lead and nickel simultaneously from drinking water. The analysis showed that immobilization makes these biosorbent 'beads' easier to remove from the solution after biosorption as compared to the process of separating FVPs particles dispersed in the solution. In addition, immobilizing these FVPs on sodium alginate 'vehicle', which has biosorbent properties of its own, produced some biosorbents that had significantly higher biosorption% and smaller reaction times as compared to equilibrium times of empty 'vehicles' (2-3 days). The elements in the study demonstrated different affinities for the six FVPs at different time points. Equilibrium biosorption was found to be 21% (As V), 92% (Cd II), 34% (Cr VI), 87% (Cu II), 90% (Hg II), 85% (Pb II) and 80% (Ni II) with minimum biosorbent dose for 0.1 mg L$^{-1}$ cocktail solution. Biosorption could be increased by increasing the FVP dose until equilibrium was attained between ions in solution and that on the biosorbent surface beyond which it was not possible to increase uptake by the unmodified FVPs. This was established by using the same metals in cocktail solution at 1 mg $L^{-1}$.

**WP259 Importance of understanding the toxicity values available for chromium, potentially complete routes of exposure and implications for remediation**

*C. Peterson, T. Biksey, EHS Support LLC / Risk Assessment*

Often in site characterization investigations, total chromium analysis is performed on soil and water samples, especially if hexavalent chromium (chromium[VI]) was not a chemical used in historical operations. Toxicological values are not available for total chromium, but rather the two valence states: chromium(VI) and trivalent chromium. Commonly, assessors and regulatory agencies default to use of the more conservative chromium(VI) screening to evaluate total chromium soil data and select constituent of potential concern (COPCs). The US Environmental Protection Agency (USEPA) Regional Screening Level (RSLs) for soil and tapwater are primarily based on the oral carcinogenic toxicity values for chromium(VI). However, upon closer examination, the USEPA Integrated Risk Information System did not identify data to support carcinogenicity by the oral route of exposure. Therefore, it may be more be more appropriate to use the non-carcinogenic toxicity value to generate the screening levels used for selection of COPCs and calculation of oral hazards in a human health risk assessment. The chromium(VI) residential soil carcinogenic screening level (target risk of $10^{-6}$) is 0.3 milligrams per kilogram (mg/kg), while the non-carcinogenic screening level (target hazard index of 0.1) is 23 mg/kg (USEPA RSLs tables, May 2018). The increase in screening level may reduce the footprint of potential remedial effort significantly because the screening level based on the non-carcinogenic toxicity value is two orders of magnitude greater than the carcinogenic screening level. While the IRIS did not find evidence of oral carcinogenicity for chromium(VI) it did find evidence of carcinogenicity through the inhalation route. Therefore, it is important to take into consideration the potentially complete exposure pathways identified for a site when conducting a human health risk assessment evaluating chromium as a COPC.

**WP260 Innovations in groundwater remediation driven by extremely challenging, emerging contaminants: 1,2,3-Trichloropropane (TCP)**

*P.G. Tratnyek, Oregon Health & Science University / School of Public Health; A. Salter-Blanc, Jacobs; Y. Lan, G. O'Brien Johnson, R. Johnson, T. Torralba-Sánchez, Oregon Health & Science University / School of Public Health; E. Bylaska, Pacific Northwest National Laboratory / Environmental Molecular Sciences Institute*

Groundwater can be contaminated with 1,2,3-Trichloropropane (TCP) from industrial and agricultural activities, and very low concentrations of TCP are of concern (CA recently adopted an MCL of 5 ppt), so treatment of TCP contaminated groundwater is an emerging challenge. Since TCP is not removed efficiently or rapidly by established methods of groundwater remediation (e.g., by adsorption to GAC or dechlorination with zerovalent iron), it has become a test case for innovative remediation technologies. We have explored several of these, most notably zerovalent zinc (ZVZ), but also sulfidated nano ZVI, bisulfite-activated permanganate, etc. The dechlorination of TCP by ZVZ is of particular interest because it exhibits very high selectivity for reductive beta-elimination over hydrogenolysis. Molecular modeling indicates that reductive elimination is thermodynamically and kinetically favored, but the zinc also appears to contribute to this selectivity. ZVZ has proven effective for remediation of TCP in several pilot-scale field tests. TCP can be degraded under conditions of several advanced oxidation technologies, but their performance has not been sufficiently promising to lead to field applications.

**WP262 Remediation of Microcystins in Drinking Water Treatment Plant Waters and Sludges with Electron Beam Irradiation**

*A. Folcik, Texas A & M University / Interdisciplinary Program in Toxicology; C. Klemashevich, Texas A&M University / Protein Chemistry Laboratory; S.D. Pillai, Texas A&M University / Interdisciplinary Program in Toxicology*

Harmful algal blooms (HABs) pose serious threats to human and animal health, and aquatic ecosystems. HABs can occur in any nutrient rich aquatic environment, especially drinking water sources. The cyanobacterium *Microcystis aeruginosa* is commonly associated with HABs and is responsible for producing various hepatotoxic heptapeptides termed microcystins. Of the over 80 variants of microcystins, microcystin-LR (MC-LR) is the most prevalent and the most toxic. Microcystin's biological activity comes from the unusual amino acid (2S,3S,8S,9S)-3-amino-9-methoxy-2,6,8-trimethyl-10-phenyldeca-4,6-dienoic acid (ADDA) which results in the inhibition of protein phosphatase 1 and 2A in humans. Disruption of this pathway ultimately results in liver inflammation, hemorrhaging, acute pneumonia, and has a potential to promote tumor growth. Ozonation is the only known microcystin removal technology for the drinking water industry. Though relatively effective for drinking water, it is not a feasible technology for remediating treatment plant sludges that could have high microcystin concentrations. Due to its toxicity, states like Ohio now classify such sludges as hazardous waste that cannot be landfilled, creating a need for new decontamination or remediation technologies. Our underlying hypothesis is that high energy electron beam (eBeam) irradiation technology, an advanced oxidation/reduction process, could be effective for the detoxification of microcystin-contaminated water, sludges, and sediments. Data suggests that even at low eBeam doses (< 5 kGy), MC-LR is completely destroyed in aqueous samples. Samples dosed with only ~400 Gy were found with less than 1% of microcystin remaining in comparison to untreated samples as determined through LC-MS/MS. Similar results were obtained using the ADDA-specific Enzyme-Linked Immunosorbent Assay (ELISA) as described by EPA method 546. Dosed samples showed a decline in MC-LR to below the 0.15 ppb detection limit of the assay. EBeam technology, which relies on accelerating electrons, does not involve the use of chemicals. Thus, eBeam technology has the potential to be a sustainable and more cost-effective alternative treatment strategy for such applications.

**WP263 The Mechanistic Study of Perfluorooctanesulphonate (PFOS) Adsorption on Nano Alumina**

*F. Wang, Jinan University*

The interaction of pollutants with nanomaterials has attracted many attentions due to the extensive application of diverse nanomaterials. In this study, PFOS was selected to investigate its adsorption behavior on nano alumina with different shapes. Firstly, the adsorption kinetic and isotherm of PFOS on alumina nanoparticles (NPs) and nanowires (NWs) were studied, and the thermodynamic parameters were calculated for better understand the adsorption behavior. Then the effects of solution chemistry (including: pH, ionic strength, and humic acid) on adsorption were further studied. Based on these results, the adsorption mechanisms were proposed from perspectives of particle properties, solution chemistry, and aggregation effect. The different aggregation behavior of alumina NPs and NWs were found to be the critical factor for PFOS adsorption, which was further proved by the dynamic light scattering (DLS) experiments. This study is the first to study the aggregation effects on PFOS adsorption on nanomaterials and the results should be useful to identify the important roles of shape and aggregation of nanomaterials for the fate of organic pollutants in environment.

**WP264 Effect of the support on the catalytic activity of Mo catalysts in the hydrodechlorination of PCDD/Fs and dl-PCBs**

*S.L. Herrera-Mejía, A. Villa, Universidad de Antioquia / Chemical Engineering Department, Faculty of Engineering, Universidad de Antioquia, Medellín; B. Johnson-Restrepo, University of Cartagena / Chemistry and the Environment Group / School of Exact and Natural Sciences*

Catalytic hydrodechlorination is an effective method for the removal of polychlorinated dibenzo-p-dioxins (PCDDs), polychlorinated dibenzofurans (PCDFs) and polychlorinated biphenyls, similar to dioxins (dl-PCBs) due to the moderate operating conditions required and the relatively low operating costs. However, the catalyst to be used must be resistant to poisoning by hydrochloric acid formed during the reaction. The PCDD/Fs and dl-PCBs are unintentionally generated in combustion processes, where they are present in its gaseous emissions and solid wastes, such as fly ashes. In catalytic hydrodechlorination of organochlorine compounds, although Pd is considered as the most active and selective metal, it has been found that this catalyst is fastly deactivated. The aim of this work is to evaluate the catalytic hydrodechlorination of extracts of PCDD/Fs and dl-PCBs using Mo supported, by wet incipient impregnation, on g-alumina (g-$Al_2O_3$), silica ($SiO_2$) and activated carbon (AC); catalysts were characterized using BET, XRD, $NH_3$-TPD and UV–vis spectroscopy. The initial total concentration of the furans almost doubled the initial total concentration of the dioxins and exceeded by more than 40 times the initial total concentration of the dl-PCBs, The congener that had the highest initial concentration (7971 pg/mL), among the group of furans, was 2,3,4,7,8-PeCDF; therefore, it has a large contribution to the total toxicity of this group (51%). The congener that had the highest initial concentration (3685 pg/mL) among the group of dioxins was 1,2,3,4,6,7,8-HpCDD (1.9%); however, it does not have a high toxic equivalence factor. The congener 1,2,3,7,8-PeCDD has the main contribution (61%), with a concentration of 1203 pg/mL. The congener of the group of dl-PCBs that contributed the most was PCB 126 (1002.33 pg/mL), which has the highest toxic equivalence factor, with a large toxicity contribution (89%). In general, the contribution to the toxicity of furans was 69.1%, dioxins 29.2% and dl-PCBS 1.7%. Reduction in toxicity was slightly higher in dioxins than in furans over the tested catalysts. The catalyst that most reduced the congener with the highest toxicity was MoA (302.77 pg/mL). The order of activity of the catalysts for all the PCDD/Fs congeners was MoA > MoCA > $MoSiO_2$ and for the dl-PCBs congeners was MoA > $MoSiO_2$ > MoCA. The catalytic activity of Mo supported on g-$Al_2O_3$, for hydrodechlorination, is comparable to the literature (71 – 99%).

## Protecting Freshwaters from Salinization

### RP001 Effects of temporal variability of salt disturbance on leaf decomposition and leaf shredder activity

E. Dobry, G. Schoeniger, Penn State Behrend

The heightened presence of road deicing salt in streams, as a result of increased use during winter months, is a disturbance that interferes with aquatic ecosystem functioning. Leaf shredding insects, which are particularly sensitive to salinity in freshwater ecosystems, aid in the decomposition of leaf litter and are an important indicator of the health of streams. Loss of these invertebrates impacts not only the health of streams, but the recreational value of these ecosystems through accumulation of detritus. With the need to balance ecosystem health with retaining human safety during winter months, research evaluating the extent to which deicing salts impact leaf shredding insects and nutrient cycling in streams is needed. The goal of this research was to evaluate how temporal variability of salt delivery within streams affects leaf shredding organisms and leaf litter decomposition. To explore this, Tipulidae larvae were exposed to one of five road deicing salt treatments at 6°C for 33 d in laboratory mesocosms. Treatments included no salt (Control), constant salt concentration (2.75 g/L) (Press), gradual increase of salt concentration (Ramp), pulsed concentration with return to baseline (Pulse Return), and pulse with increased baseline (Pulse Ramp). Decomposition rate of leaf litter, Tipulid growth rate, and survival were monitored over the course of the study. Leaf litter mass lost was significantly greater in the two pulsed treatments than any other treatment, suggesting changing salt concentrations caused increased feeding in exposed Tipulids compared to other treatments. Despite greater consumption, Tipulid mass lost in the pulsed treatments did not vary significantly from other treatments. We hypothesize this result indicates increased osmoregulatory costs to tipulid larvae in the treatments with changing salt concentrations. Such costs may affect their ability to grow and reproduce, thus impacting the health of the streams as important shredder populations disappear.

### RP002 Evaluating the efficacy of native halophytes in the phytoextraction of sodium chloride (road salt) from contaminated soil

E. Mann, Queens University / School of Environmental Studies; B. Zeeb, Royal Military College / Chemistry Chemical Engineering Dept; A. Rutter, Queens University / School of Environmental Studies

Soil and freshwater salinization is a growing issue worldwide. Road salt, primarily sodium chloride, is a significant contributor to freshwater salinization in North America. When road salt is applied, it leaches into the roadside soil where it can accumulate, or leach further into nearby water systems. Increasing salinity poses a threat to both terrestrial and aquatic life, often creating inhabitable conditions. Salt tolerant plants, known as halophytes, thrive in saline soil, and select species are able to remove the salt from the soil, a process known as phytoextraction. Salts taken up from the soil are stored in the above ground biomass, and by harvesting this plant material salts can be removed from the soil before entering the water table. This study investigated the ability of four native halophytes: *Atriplex canescans, Atriplex patula, Atriplex hortensis,* and *Spartina pectinata* to remove sodium chloride from soil. Both field and greenhouse studies were completed in order to determine survivability in roadside areas, and $Na^+$ and $Cl^-$ extraction rates. This research aims to inform remediation and management practices for road salt contaminated soil in order to reduce the environmental impact of road salting. By intercepting the salt at the roadside, before it can leach further downstream, phytoremediation offers a proactive approach to mitigating freshwater salinization.

### RP003 Identifying and Evaluating Major Ion Toxicity of Coal Combustion Residual Landfill Effluents

S. Edmonds, L.T. Yonkos, University of Maryland / Environmental Science and Technology; C. Michelmore, University of Maryland Center for Environmental Science / Chesapeake Biological Laboratory; D.J. Fisher, University of Maryland / Environmental Science and Technology /Wye Research and Education Center

This project investigates the toxicological consequences of leachate from "dry" coal ash disposal on water quality and biota in receiving waters. The study includes quarterly whole effluent toxicity tests on discharge samples from three Maryland disposal facilities. Results indicate varying levels of chronic toxicity at all three locations. Priority metals and major ions have been measured and monitored over time and concurrently with bioassays. The wastewaters were found to be consistently high in total dissolved solids (TDS) and high conductivities were consistently observed, both indicative of elevated major ions. Traditional phase 1 toxicity identification evaluation (TIE) methods are not effective at addressing these issues. Models for predicting acute toxicity of a number of salt mixtures to *Ceriodaphnia dubia* have been developed, however, the thresholds at which chronic reductions in reproduction occur is still uncertain. Therefore, the purpose of the present study is to evaluate the toxicity associated with major ion imbalances using mock effluents and a weight-of-evidence approach in order to determine and confirm the primary causative ions. Calcium, chloride, magnesium, sodium, potassium, and sulfate were used to create a reconstituted mock effluent. A 7-day static renewal dilution series was completed using *Ceriodaphnia dubia* and threshold inhibition concentration values (IC25s) were compared between the reconstituted mock effluent and the wastewater. Subsequent toxicity tests were completed targeting single salts and salt mixtures in order to evaluate ion interactions and mechanisms of toxicity, as well as the ameliorative effects of ions in mixtures. Results of this work will advance our understanding of the relative risk of major ion imbalances in freshwater systems and can be used to refine treatment systems surrounding coal combustion residual facilities.

### RP005 The sensitivity of freshwater mussels to salt-laden winter bridge runoff; implications for mussel species at risk

P. Gillis, Environment and Climate Change Canada / Aquatic Contaminants Research Division; J. Salerno, Environment and Climate Change Canada / Water Science Technology; V. McKay, Lower Thames Valley Conservation Authority; C.J. Bennett, Environment and Climate Change Canada / Water Science and Technology; A. Pratt, Lower Thames Valley Conservation Authority; Q. Rochfort, Environment and Climate Change Canada / Water Science Technology; R.S. Prosser, University of Guelph / School of Environmental Sciences

The increase in chloride (Cl) concentrations in North American surface waters over the past 30 years correlates with the increased application of de-icing salts. Freshwater salinization has implications for ecosystem health as chloride levels in urban streams frequently exceed those that are harmful to aquatic life. In winter, de-icing salt builds up in snowbanks on impermeable surfaces such as roads and bridges. When the temperature rises, the resulting salt-laden meltwater can be conveyed to aquatic habitats directly through bridge runoff or via overland flow. The early life stages of freshwater mussels are very sensitive to salt. This study focused on the Thames River (ON) watershed, the second most species-rich watershed for mussels in Canada. Two bridges in relative proximity to a four-lane expressway that span freshwater mussel species at risk habitat were targeted. The bridge's structures are such that runoff has different entry routes to the creeks below. Runoff from the Baptiste Creek bridge flows directly into the creek, whereas runoff from the McGregor Creek bridge travels through a tile drain before it enters the river. The concentration of chloride at the targeted sites was assessed throughout the year. During winter melt events, chloride and other contaminants were quantified in samples of snow from the bridges, bridge drain water, and creek surface water upstream and downstream of the targeted bridges. Mussel larvae (glochidia) were exposed to samples of field-collected meltwater in the lab using standard methods. Throughout the year, surface water in Baptiste Creek ranged from 9 to 89 mg Cl/L and McGregor Creek ranged from 39 to 323 mg Cl/L. In both cases, the maximum chloride concentrations corresponded to the colder season. Lab exposures with serial-diluted meltwater revealed 48-h EC50s for *Lampsilis fasciola* glochidia of 26.4% meltwater (2,764 mg Cl/L) at Baptiste Creek bridge (bridge deck drain sample = 8,250 mg Cl/L) and 43.8% meltwater (1,517 mg Cl/L) at McGregor Creek bridge (tile drain sample = 3,110 mg Cl/L). The distribution of freshwater mussels surrounding the targeted bridges is being examined to determine whether the toxicity observed in early life stage mussels exposed to winter road runoff in the lab translates into altered freshwater mussel distribution in the natural habitat.

**RP006 Toxic effects of "environmentally-friendly" deicing alternatives on Chironomus dilutus and a toxicologist's role in green marketing**

*M. Solan, Penn State Behrend; S. Nutile, Penn State Univ., The Behrend College / Biology*

Recent studies on the effects of increasing road salt pollution on aquatic organisms has incited development of new deicing formulations, many marketed as "environmentally friendly." With the ever-increasing development of "eco-friendly" products, the portion of the environment for which these products are aimed at protecting becomes increasingly blurred. As traditional deicing formulations consisting primarily of sodium chloride are well documented to significantly impact the health of aquatic ecosystems. As such, "environmentally-friendly" deicing alternatives may offer a solution to protecting human and aquatic health. Therefore, the goal of the current study was to determine the toxicity of traditional deicing formulations versus those deemed "environmentally friendly" using 10-d toxicity tests involving *Chironomus dilutus*. Second instar *C. dilutus* were exposed to either the reference toxicant (NaCl) at one of five concentrations (3.0, 4.5, 6.0, 7.5 or 9.0 g/L) or one of three alternative deicing formulations (calcium magnesium acetate, beet juice, urea) at concentrations determined via preliminary range finding tests. Lethal concentration 50 (LC50) values of each deicing formulation reveals the three "eco-friendly" deicing alternatives were equally or more toxic than traditional sodium chloride based deicing formulations to *C. dilutus*. Given these results, the role of toxicologists in validation of green marketing tactics is called into question. While these three formulations were not more protective of aquatic invertebrates, were they ever intended to be by the manufacturer? Developing a clearer definition of "eco-friendly" to ensure consumers are clear about the role they play in affecting and protecting aquatic environments upon which we all rely would aid in defining the role of green marketing in advancing scientific understanding.

## Assessment and Monitoring of Risks to Aquatic Environments from Short-Term (Episodic) Contaminant Exposures

**RP007 Exposure to untreated urban wastewaters alters growth and reproduction in *Daphnia magna***

*T.L. Colson, Environment and Climate Change Canada / Aquatic Contaminants Research Division; M. Giraudo, M. Lépine, Environment and Climate Change Canada; M. Douville, C. Gagnon, M. Houde, Environment and Climate Change Canada / Aquatic Contaminants Research Division*

In November 2015, the repair of a sewage interceptor necessitated that nearly 5 billion liters of untreated wastewater (UWW) be diverted from a primary wastewater treatment plant (Montreal, QC, Canada) and discharged into the St. Lawrence River over the course of four days. These untreated UWWs originated from household, industrial, and hospital sources. The objective of this study was to investigate the effects of this planned UWW release on aquatic organisms in order to gain insight into the potential impacts of the increasing number of heavy rain events which may lead to unplanned UWW spills. Water samples were collected from four different sites along the St. Lawrence River during and four weeks after the release. Due to their high abundance as well as their importance in the St. Lawrence River food web, *Daphnia magna* were used as a model species. *Daphnia Magna* were experimentally exposed to the collected UWW from each site for 13 days and analyzed for a suite of biomarkers related to oxidative stress (i.e., catalase, superoxide dismutase, lipid peroxidation, and glutathione-*S*-transferase) and reproduction (chitinase). Results indicated that daphnid growth and reproduction were significantly impacted by the exposure to UWW when compared to the un-impacted reference site. Body size was smaller in *D. magna* exposed to UWW from one site and the number of neonates produced at that site was higher and decreased significantly after the event, suggesting long term reproductive impacts. These life-history-related effects were correlated with an increase in chitinase activity which is controlled by reproductive hormones and involved in growth. Overall, results suggest endocrine disruption potential of the UWW in these aquatic invertebrates. This study may contribute to a better understanding of the biological impacts of UWW to aquatic invertebrates.

**RP008 Short-Term in situ Monitoring Response of Diffusive Gradients in Thin Films in Marine Waters for Pulse Capture of Cd, Cu, Ni, Pb, and Zn**

*J. Strivens, PNNL / Coastal Sciences; R. Johnston, Space and Naval Warfare Systems Center Pacific; G.H. Rosen, SPAWAR Systems Center / Energy and Environmental Sustainability; N. Schlafer, Pacific Northwest National Laboratory / Marine Sciences Laboratory; N. Hayman, SPAWAR Systems Center Pacific / Energy and Environmental Sustainability; J. Brandenberger, Pacific Northwest National Laboratory / Marine Sciences Laboratory; R. Gauthier, Space and Naval Warfare Systems Center Pacific; P. Caswell, Puget Sound Naval Shipyard & Intermediate Maintenance Facility; M. Jabloner, H. Jennings, NAVFAC Northwest*

The ambient monitoring program, Project ENVironmental inVESTment (ENVVEST), being conducted for the Puget Sound Naval Shipyard & Intermediate Maintenance Facility (PSNS&IMF) in the Puget Sound receiving waters of Sinclair and Dyes Inlets, has conducted in situ aqueous metal bioavailability monitoring using diffusive gradients in thin film (DGT) passive samplers. In situ campaigns to record labile ($C_{DGT}$) Cd, Cu, Ni, Pb, and Zn have deployed DGTs in a manner that allows for short-term response characterization for deployment times ranging from 24 to 72 hours in low to moderate ambient conditions, and also overlaid in a manner that allows for capture of stormwater related fluctuations. The average relative percent difference (RPD) for 24 hour duplication, $n$=8, was 4±3, 15±18, 12±11, 135±62, and 57±44 for Cd, Cu, Ni, Pb, and Zn respectively; at ambient labile levels of 0.0368±0.00370, 0.302±0.104, 0.233±0.0267, 0.00640±0.0020, and 3.68±1.35µg $L^{-1}$. The average $C_{DGT}$ RPD when overlaying a 72 hour deployment onto consecutive 24 hour deployments, $n$=8, was 3±2, 18±14, 10±9, 45±20, and 79±36 for Cd, Cu, Ni, Pb, and Zn respectively. Metals with poor short-term performance, Pb and Zn, were affected by initial hyper-accumulation; which for Pb reflected values below the calculated $C_{DGT}$ MDL due to low ambient concentrations, and for Zn is theorized to be a naturally occurring result of proximity to industrial input sources. This initial dataset validates short-term DGT deployments for monitoring labile Cd, Cu, and Ni in seawater for the tested concentration range, and was followed by 8-72 hours deployments over a 2 week period, during both wet and dry seasons, at 7 stations within PSNS receiving waters.

## Improving Approaches to Assess Risks to Threatened and Endangered Species from Chemical Exposure

**RP009 Optimizing and evaluating a simplified toxicokinetic toxicodynamic model for predicting effects of pulsed exposure to carbaryl on fathead minnow**

*S. Kadlec, USEPA via NRC / ORD / NHEERL Mid-Continent Ecology Division; M. Etterson, N. Pollesch, K. Flynn, USEPA / ORD / NHEERL Mid-Continent Ecology Division*

The effects of pulsed and time-variable exposures to chemicals may be under- or over-estimated with environmental risk assessment approaches based on standard, constant-exposure toxicity tests. However, fully calibrating models to predict the effects of pulsed exposures requires experimental data that are resource-intensive to gather and are not routinely provided for the EPA's pesticide registration process. Previous researchers have suggested that standard 96-h acute and 30-d early lifestage toxicity test data may be used to parameterize a simplified toxicokinetic, toxicodynamic (TKTD) model, resulting in predictive power equivalent to a full model. Our team is developing an efficient protocol using R to evaluate the characteristics of toxicological datasets that result in successful parameter estimation for this simplified model, and to select the toxicological data that results in models with optimal predictive power. We demonstrate our methods and results using the effects of carbaryl on fathead minnow survival as an example, with datasets derived from both standard and non-standard toxicity test endpoints, as well as literature-estimated parameters. We also discuss the possibility of accounting for size-dependent sensitivity and sublethal endpoints within these models, developing a generalized model for other species/chemical combinations, and using pulsed exposure effects model outputs to inform population models. This work is a part of the fish population model development at EPA-MED, presented elsewhere during this session.

**RP010 Extrapolating from Laboratory-based Aquatic Toxicity Tests to Fish Populations: Data from Diazinon and Carbaryl Exposures**

*K. Flynn, N. Pollesch, USEPA / ORD / NHEERL / Mid-Continent Ecology Division; S. Kadlec, USEPA via NRC / ORD / NHEERL Mid-Continent Ecology Division; F. Whiteman, M. Etterson, USEPA / ORD / NHEERL / Mid-Continent Ecology Division*

The United States Environmental Protection Agency (USEPA) assesses the risk of pesticides that are registered under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) to the environment and non-target wildlife and fish. A fundamental challenge in this process is the extrapolation from laboratory-based aquatic toxicity testing, which collects data on the individual fish, to population-level impacts. Currently, we are developing a structured population modeling (called the Fish Translator) that is intended to bridge the gap between effects observed in standardized aquatic toxicity tests often submitted during the FIFRA pesticide registration process, and potential outcomes of pesticide exposure to fish populations. As part of this research effort, laboratory tests on fish exposed to pesticides have been conducted to provide data on the relationship between growth and reproductive output (*i.e.* initiation of spawning, duration of spawning, and fecundity) to help parameterize the Fish Translator model. Specifically, Japanese medaka (*Oryzias latipes)* were exposed to either diazinon (an acetylcholinesterase inhibitor), reared at reduced food rations, or both to dis-entangled the reproductive and growth effects of a pesticide and the relationships between exposure, growth, and reproduction. Additionally, a standard Fish Early Life Stage Test (OCSPP 850.1400) with carbaryl (another acetylcholinesterase inhibitor) was conducted, exposing fathead minnows (*Pimephales promelas*) which were then reared without exposure to reproductive competence. The goal is to link adverse outcomes of an early life exposure (data often submitted under FIFRA) to adverse reproductive outcomes later in life that, in turn, are applicable to populations and population modeling. The effects observed in the laboratory of these two pesticides on the reproductive output of either Japanese medaka or fathead minnow were used in the Fish Translator to predictive population-level impacts on fish species with similar life history parameters.

**RP011 Assessing the Population Impacts of Pesticides on Delta Smelt**

*M. Etterson, N. Pollesch, S. Kadlec, K. Flynn, USEPA / ORD / NHEERL / Mid-Continent Ecology Division*

Under section 7 of the US Endangered species act,USEPA is responsible for ensuring that its actions, including pesticide registrations, do not place federally listed species at jeopardy. Here we evaluate the utility of a new USEPA fish population model, protoyped for Fathead Minnow (*Pimephales promelas*) when parameterized and applied to Delta Smelt (*Hypomesus transpacificus*), a federally listed endangered species. The model is a size-structured integral projection model that can incorporate chemical and non-chemical stressors to estimate effects on population trajectories. Here we present how this modeling framework can be adapted for the life history of the delta smelt, where different life-stages occupy spatially distinct areas, reproduction is semelparous, and pesticide exposure occurs in pulses.

**RP012 Implementing a flexible approach to address the risk of pesticides to threatened and endangered species**

*T. Hawkes, National Marine Fisheries Service / Office of Protect Resources; R.J. DeWitt, The Evergreen State College / Office of Protected Resources Endangered Species Division; S.A. Hecht, NOAA / National Marine Fisheries Service; T. Hooper, NOAA / NMFS*

Pesticides are tools commonly used to manage habitat and to control unwanted pests, but their use comes with inherent risks. Management of the risks to listed species is complicated by the fact that listed species are widely distributed into a variety of habitats throughout the United States and site-specific factors highly influence risk. For example, the presence of riparian buffers can mitigate risk to aquatic species by improving water quality and reducing pesticide loading into aquatic habitats. A "one size fits all" approach to managing risk is not always necessary or desired. In a recent Biological Opinion, the National Marine Fisheries Service (NMFS) proposed the option of managing risk using a "flexible toolbox approach" conceptually similar to that described in the proceedings from the recent SETAC MAgPIE workshops. This presentation will outline the NMFS approach which essentially awards risk reduction points depending on site-specific characteristics, application-specific methodology, and the use of drift reduction technologies. This approach encourages partnerships, recognizes land managers and pesticide applicators that participate in approved conservation activities and pesticide stewardship plans, and provides site-specific flexibility in reducing pesticide risk at a nationwide scale.

**RP013 Save Two Birds with One Stone: Protect Listed Species & Ecosystem Services in Geographically Isolated Wetlands Using Community-Level Protection Goals**

*L. Oliver, USEPA; S. Raimondo, L. Sharpe, USEPA / Gulf Ecology Division; T. Purucker, USEPA / Ecosystems Research Division*

Geographically Isolated Wetlands (GIWs) are unique geological features that provide habitat for a number of endemic and endangered and threatened animal and plant species, as well as providing a number of ecosystem services (ES). GIWs are threatened by a range of chemical contaminants that vary based on region and assessing potential impacts to the fragile communities they embody is a challenge. We propose an approach that develops community-level protection goals for GIWs that include both listed species and taxa that drive ES for ecological risk assessments (ERAs). Community-level protection goals are derived by weighting the prioritization of listed species followed by taxa providing ES, allowing a single risk ERA to establish protection levels for multiple species in one process. We identify chemical hazards specific to each type of GIW within the US and derive protection goals for each based on their community of endemic and listed species and ES components. We discuss exposure pathways for GIWs in general and examples of exposure and effects models that can be used to achieve the protection goals. We also explore weight of evidence approaches that aid in establishing hazard concentrations based on contaminant type, exposure pathways, and available effects data. We demonstrate the process using a case study of vernal pools in California's central valley.

## Current-Use Pesticides: Exposure and Effects on Non-Target Organisms and Ecosystems

**RP014 Pesticide distribution trends in the Canadian Prairie Pothole Region**

*E. Malaj, K. Liber, University of Saskatchewan / Toxicology Centre; C.A. Morrissey, University of Saskatchewan / Biology*

Pesticides often occur in wetland ecosystems as complex mixtures with strong seasonal and geographic distribution. Frequently detected pesticides in the Canadian Prairie Pothole Region (PPR) are likely related to the high intensity use of these compounds and to the crop type surrounding the wetlands. Pesticide use estimates that link these two variables will be presented in order to identify the main factors that drive pesticide spatial distribution and prioritize areas for future large-scale, targeted pesticide sampling in Prairie wetlands. Using a GIS-based modeling, we estimated the spatial distribution of key pesticides in the PPR. The use distribution was computed by intersecting percentage land cover with application rates for each crop and province. The application rates were derived from a large commercial survey conducted in 2015. There were 12 insecticides, 35 fungicides and 56 herbicides used in the PPR in 2015. All insecticides were used for the insecticide distribution model, whereas for herbicide and fungicide models compounds were prioritized based on mass, ecotoxicological relevance and fate data. Pesticide distribution models were able to identify specific use hot-spots in the PPR, which were primarily related to canola and wheat crops. The province of Saskatchewan had the highest application rates for all three groups of pesticides (insecticides, herbicides and fungicides). For example, use of the insecticide chlorpyrifos was 22-fold higher in Saskatchewan compared to the other provinces of Alberta and Manitoba. Based on these results and the distribution of water in the Prairies, two monitoring campaigns were designed for implementation in 2017 and 2018 with the ultimate goal of estimating the ecological risk from pesticides in PPR wetlands.

**RP015 Neonicotinoids and phenylpyrazoles, metabolites and pesticide synergists in surface waters and sediment samples of British Columbia, Canada**

*M. Woudneh, SGS AXYS Analytical Services Ltd.; C.A. Bishop, Environment and Climate Change Canada / Wildlife Research Division; J.E. Elliott, Environment and Climate Change Canada / Science and Technology Branch / Ecotoxicology and Wildlife Health Division; B. Chandramouli, SGS AXYS; C. Hamilton, SGS AXYS / Client Services; R. Grace, J. Cosgrove, SGS AXYS*

Neonicotinoid and phenylpyrazole insecticides have received significant attention due to suspected effects on non-target aquatic and terrestrial insects. Current analytical approaches for these analytes do not typically measure insecticide metabolites, which are also toxic, and may not include pesticide synergists, whose presence can increase the toxicity of the insecticides. In the present work, we developed an isotope dilution ultra high-performance liquid chromatography (UHPLC) tandem mass spectrometric method for the quantitative measurement of 8 neonicotinoids and 6 neonicotinoid metabolites, the phenylpyrazole fipronil and 4 of its degradation products, and 2 commonly used pesticide synergists. The method used ultrasonic extraction followed by solid phase clean-up for solid samples and solid phase extraction and cleanup for aqueous samples. Sample extracts were analyzed by UHPLC (+/-)ESI MS/MS. The method's detection limits ranged from 1.25 to 2.5 ng/L for the insecticides, 1.25 to 40 ng/L for the metabolites and 1.25 to 10 ng/L for the pesticide synergists in aqueous samples. Detection limits for sediment samples ranged from 0.1 to 0.2 ng/g, 0.2 to 3.2 ng/g, and 0.1 to 0.8 ng/g wet weight respectively. In replicate spike recovery experiments, n=5, recovery for the phenylpyrazole fipronil and its metabolites ranged 97-100% (RSD 0.9 – 3.1%) in aqueous and 99-106% (RSD 0.9-8%) in solid samples. Similarly, recovery for neonicotinoids and their metabolites ranged 69-125% (RSD 2-11%) in aqueous samples and 55-120% (RSD 2-24%) in solid samples. Performance measures were satisfactory for all targets except imidacloprid urea where some low recoveries were observed in both aqueous and solid samples. The developed method was applied for analysis of paired water and sediment samples from three diverse sites in British Columbia, Canada. Sampling locations included five sites near agricultural land use, five sites near urban land use and two reference sites. The partitioning behavior of these contaminants will be discussed. This data contributes to our understanding of the occurrence, fate and behaviour of some of the most widely used insecticides in the world.

**RP016 Imidacloprid use and contamination in surface waters in the Central Coast and Imperial Valley, California**

*X. Deng, California EPA / Surface Water Protection Program; D. Wang, California Department of Pesticide Regulation; A.S. Burant, California Department of Pesticide Regulation / Surface Water Protection Program; C. DeMars, N. Singhasemanon, K. Goh, California Department of Pesticide Regulation*

Imidacloprid is an insecticide that has been regularly monitored in California's Salinas, Santa Maria, and Imperial valleys since 2010 by the California Department of Pesticide Regulation's Surface Water Protection Program (SWPP). The three regions represent agricultural croplands dominated by row crops. Typically, irrigation practices on row crops tend to generate higher pesticide runoff that has the potential to pollute aquatic environments adjacent to pesticide-treated fields. SWPP monitoring events occurred during the dry season in each region to coincide with the period of highest imidacloprid use during the year. Imidacloprid use exhibits distinct regional patterns. Crops with the highest use are lettuce in the Salinas Valley, broccoli in the Santa Maria Valley, and sugar beet and lettuce in the Imperial Valley. Imidacloprid was detected in 85% of 380 samples collected from 30 sites during the dry season in 2010–2016 making it the most detected compound among all the pesticides monitored by SWPP. When comparing reported concentrations to the recently revised USEPA imidacloprid aquatic life benchmarks, 52% of the samples had imidacloprid concentrations that exceeded the acute benchmark of 0.385 μg/L, and all the samples had concentrations that exceeded the chronic benchmark of 0.01 μg/L. Among the three regions, the watersheds in Santa Maria showed significantly higher detection frequencies and concentrations, followed by those in Salinas and Imperial. Site-specific analyses will be conducted at the catchment and watershed levels to elucidate the high surface water concentrations associated with imidacloprid use patterns.

**RP017 Ultra-trace analysis of pesticides by HPLC-MS/MS: A pilot survey of drinking water, fruit, and vegetables in Quebec, Canada**

*J. Montiel Leon, S. Vo Duy, G. Munoz, Universite de Montreal / Chimie; M.Y. Hendawi, Zagazig University / Plant Protection; H.E. Moya Rojas, Pontificia Universidad Católica de Valparaíso / Escuela de Agronomía; M. Amyot, Universite de Montreal; S. Sauvé, Universite de Montreal / Chemistry*

The extensive use of certain pesticides and their relative persistence goes on par with the presence of residue levels in drinking water and/or agricultural products available to consumers (including food commodities), with possible implications for human exposure. In view of these findings, quality standards have been proposed for drinking water; maximum residue limits (MRLs) of pesticides have also been established for foodstuff available to consumers. This requires the implementation of sensitive and robust analytical methods for the ultra-trace quantification of these compounds, to determine whether the different samples are compliant to guidelines or MRLs. A commonly used method for polar pesticides in water samples relies on off-line solid phase extraction (SPE) of a large sample volume followed by liquid chromatography tandem mass spectrometry. In the case of food analysis, the QuEChERS method is gaining popularity due to its wide range of application for polar compounds and cost-effectiveness. Within this context, the overarching aim of this work was to propose fast and robust analytical methods to determine multi-class pesticides in drinking water and food commodities. For water samples, we set out to develop a fully automated on-line SPE method coupled to ultra-high-performance liquid chromatography tandem mass spectrometry. The method is rapid (8 min per sample), with limits of detection in the range of 0.1–5 ng $L^{-1}$. Factors that could affect the whole-method accuracy were examined (e.g., filtration artifacts, time-dependent storage stability, and matrix effects). For fruit and vegetables, we optimized a modified dSPE QuEChERS method, e.g., by varying extraction salts and contact time as well as clean-up sorbents. The modified dSPE method showed LODs between 0.05 $ng \cdot g^{-1}$ and 2 $ng \cdot g^{-1}$. The robustness of the method was demonstrated via quality control experiments to ensure the lack of matrix effects in along the analytical sequence. The validated methods were applied to real samples including tap water samples covering 50 cities in the Quebec province (Canada), and 133 samples of lettuce, apple, grapes, and tomatoes purchased across local markets. The results indicate the occurrence of thiamethoxam, clothianidin and imidacloprid in the water samples and four commodities. Dimethoate and triethylphosphorothioate were also occasionally observed. Nevertheless, the concentrations remained below the MRLs established.

**RP018 Pesticide Encapsulation at the Nano Scale Drives Changes to the Hydrophobic Partitioning and Toxicity of an Active Ingredient**

*M.R. Slattery, B.J. Harper, S.L. Harper, Oregon State University / Department of Environmental and Molecular Toxicology*

The multibillion dollar pesticide industry promotes innovative technologies that enhance existing products. Given the costs associated with designing novel active ingredients, many new formulations focus on the use of other ingredients to modify existing formulations. Among these developing products are encapsulated pesticides, which shield the active ingredients from immediate interactions with their surrounding chemical environment and offer a variety of enhanced features including controlled release and improved efficacy. Despite the presence of nano-sized capsules in commercial pesticide formulations, the analytical and toxicological implications of encapsulation are uncertain. Moreover, there is limited information regarding the relevance of capsule size on capsule-based effects. To explore this issue quantitatively, we fractionated the capsules of a commercially available encapsulated insecticide (γ-cyhalothrin active ingredient) into two size ranges: a large fraction (LF), with an average hydrodynamic diameter (HDD) of 758 nm, and a small fraction (SF), with an average HDD of 449 nm. We developed a novel extraction method capable of comparing the partitioning behavior of encapsulated γ-cyhalothrin, an extremely hydrophobic insecticide, with freely suspended γ-cyhalothrin. Both encapsulated fractions showed a time-dependent inhibition of γ-cyhalothrin hydrophobic interaction for up to 48 hours. To assess any capsule effects on γ-cyhalothrin toxicity, we conducted an acute immobilization test with a freshwater macroinvertebrate (*Ceriodaphnia dubia*), normalizing treatment concentration of the active ingredient. The SF was significantly more toxic than both the LF and the free γ-cyhalothrin treatment ($EC_{50}$ = 0.18 μg/L, 0.57 μg/L, and 0.65 μg/L respectively), while the toxicity of the LF was similar to the free γ-cyhalothrin. Together, these findings highlight that encapsulation of γ-cyhalothrin mitigates hydrophobic partitioning in a time-dependent manner and influences toxicity in a size-dependent manner. Recognizing the analytical and toxicological nuances of various nano-sized capsules can contribute to innovation in pesticide formulations and may lead to more comprehensive pesticide regulation.

**RP019 Composition and function of nicotinic acetylcholine receptors in *Chironomus dilutus* exposed to neonicotinoid mixtures**

*E. Maloney, University of Saskatchewan / Toxicology; C.A. Morrissey, University of Saskatchewan / Biology; M. Brinkmann, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre; K. Peru, J.V. Headley, Environment and Climate Change Canada / Watershed Hydrology and Ecology Research Division; K. Liber, University of Saskatchewan / Toxicology Centre*

Neonicotinoids and their mixtures are routinely detected in global freshwater environments and can exert greater than additive toxicity to non-target invertebrates. Previous studies have characterized the toxicities of select neonicotinoids and their mixtures using *Chironomus dilutus* as a representative aquatic test species. However, toxicological effects tend to vary depending on exposure duration and condition, mixture composition, and endpoint of concern. One hypothesis for these diverse effects is that the function and molecular composition of the nicotinic acetylcholine receptor (nAChR), the main molecular target of neonicotinoids, varies in response to exposure to different neonicotinoids and their mixtures. Therefore, this research aims to characterize the effects of select neonicotinoids (imidacloprid, clothianidin, and thiamethoxam) and their mixtures on the composition and function of nAChR in larval and adult *C. dilutus*. Lab-reared organisms were exposed to either single compounds or binary mixtures at equivalent dose-levels (28 d $\Sigma$ $EC_{12.5}$ for *C. dilutus* emergence) for 28 days. Larvae were sampled after 10 d of exposure, and emerging adults were collected until the cessation of the study. Putative *C. dilutus* nAChR subunits were identified by searching non-redundant nucleotide databases using nAChR subunits of *Anopheles gambaie* and *Drosophila melanogaster* as references. Quantitative real-time RT-PCR was used to assess nAChR transcript abundances among neonicotinoid/mixture treated larvae and adults. Radioligand binding assays were used to assess the effects of neonicotinoids/mixtures on functional expression by evaluating the affinity of expressed nAChR proteins for select neonicotinoid agonists (IMI, CLO, TMX). Results obtained will be compared to single compound/mixture toxicity models to determine if changes in nAChR composition or functional expression correlate with toxicological responses in *C. dilutus*. This will ultimately enhance our understanding of chronic neonicotinoid mixture effects on non-target aquatic insects, helping improve risk assessment practices for this class of compounds.

**RP020 Molecular effects of imidacloprid to *Chironomus dilutus* by de novo transcriptome**

*F. Wei, Guangzhou Institute of Geochemistry, Chinese Academy of Sciences / State Key Laboratory of Organic Geochemistry; J. You, Jinan University / School of Environment*

Neonicotinoids are one of the most widely used systemic insecticides all over the world. Their wide distribution in the environment has posed a threat to non-target species (Hladik et al. 2018), ultimately causing concern about risk to biodiversity and ecological function (Chagnon et al. 2015). However, molecular mechanisms underlying these effects has not been well characterized yet. This study evaluated adverse effects of a neonicotinoid, imidacloprid, to a benthic invertebrate, *Chironomus dilutus,* and explored the probable toxicity pathways by *de novo* transcriptome. Acute and sublethal toxicity of imidacloprid to *C. dilutus* were detected. With the increasing concentration of imidacloprid, midge larva lost burrowing capacity, and could not move normally by the s-shaped curve, lead to overexcitation, and finally paralysis to death. Imidacloprid produced neurotoxicity, oxidative stress, endocrine disruption and immunotoxicity by *de novo* transcriptome analysis. Molecular toxicity pathways disrupted by imidacloprid at different concentrations were evaluated by Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses. By GO enrichment analysis, sodium ion transport and mitochondrial electron transport were easily affected, suggesting possible damages on neural system and energy metabolism. Besides, chitin binding was enriched, which was related with endocrine effect. By KEGG pathways analysis, peroxisome proliferators-activated receptors (PPARs), calcium, glucagon, fatty acid degradation, apoptosis signaling pathway were enriched. These pathways were related to oxidative stress and disfunction on endocrine and nerve systems. Our study offered better understanding on molecular mechanism of imidacloprid toxicity to *C. dilutus* and helped evaluating the risk of the exposure of aquatic species to neonicotinoids at environmentally relevant concentrations. Reference Chagnon, M., D. Kreutzweiser, E. A. Mitchell, C. A. Morrissey, D. A. Noome and J. P. Van der Sluijs., 2015. Risks of large-scale use of systemic insecticides to ecosystem functioning and services. Environ. Sci. Pollut. 22, 119-134. Hladik, M. L., A. R. Main and D. Goulson., 2018. Environmental risks and challenges associated with neonicotinoid insecticides. Environ.Sci. Technol. 52, 3329-3335.

**RP021 Genotoxicity Assessment of Imidacloprid on Root Meristem of *Allium cepa***

*A. Ogunyebi, O. Olojuola, University of Lagos, Akoka / Department of Cell Biology and Genetics; K.O. Omoyajowo, University of Lagos, Akoka / Cell Biology and Genetics / Environmental Biology; E. Awe, University of Lagos / Cell Biology and Genetics*

Myriads of literatures have critically examined the toxicity of Imidacloprid as well as its possible ecological effects. However, few studies have examined its toxicity at the genetic level. In this study, the effects of Imidacloprid on *Allium cepa*, following the exposure of *Allium cepa* to different concentrations of this insecticide was evaluated. After the 96 hours of exposure, the highest growth inhibition was observed in the onions treated with 1.0mol/L of Imidacloprid measuring average length of 9mm, while the least inhibition of 13.8mm was in the control. The results demonstrated that the concentrations tested induced chromosomal alterations and also had an effect on onion growth. The sample tested with 0.4mol/L concentration of test substance recorded the highest number of aberrant cells with a total number of 14 aberrant cells. Concentrations higher than 0.4mol/L showed lesser number of dividing cells, hence lower observation of aberrant cells. Therefore, Imidacloprid in these concentrations was genotoxic to the tested organisms. Considering its genotoxic nature, information concerning the extent of its genotoxicity should be disseminated.

**RP022 Imidacloprid-containing pesticides disrupt C. elegans germline development**

*B. Bradford, P. Checchi, Marist College*

Neonicotinoids are a class of pesticide that has been under investigation by the Environmental Protection Agency (EPA) in recent years. A major concern is a possible role they may play in colony collapse disorder in honey bees, wherein neonicotinoids disrupt both their development and behavior. One example of a neonicotinoid is imidacloprid, which is an active ingredient in pesticides which are used in the agriculture industry and in pesticides available to the general public for use in lawn and garden care. Here, the effects of an imidacloprid-containing pesticide on the development of *C. elegans* was investigated. *C. elegans* is a model organism which has been used in assessing the effects of chemicals including BPA. The assessment was conducted on three different strains of *C. elegans,* wild-type, *bus-17* which has a defective cuticle and in the transgenic strain *ced-1*::GFP. The imidacloprid containing pesticide used in the investigation is one which is available to the general public and which contains imidacloprid at a concentration of 1.47%. Specifically, we investigated the effect of imidacloprid containing pesticides on the *C. elegans* germ line, a population of cells that is of particular importance as exposure to toxins can affect subsequent generations. To determine the effects of imidacloprid on germ cell development, we scored apoptotic nuclei and found that imidacloprid caused a significant increase in the number of corpses as a result of exposure to the imidacloprid containing pesticide. Accordingly, we also discovered a reduction in fertility in the offspring, as determined by brood size analysis with which exposure to the imidacloprid containing pesticide was found to lead to a significant decrease in brood size. We are currently exploring the nature of these defects, which strongly indicate that imidacloprid negatively impacts development and reduces gamete quality. Our data support findings that neonicotinoids cause widespread harm to multiple species and raise concern about their safety to humans as it shows elevated levels of apoptosis in all three strains of *C. elegans* and a reduction in fertility in response to exposure to the imidacloprid-containing pesticide.

**RP023 Long-term exposures of neonicotinoid insecticides to earthworms**

*W. Martin, R.S. Prosser, P.K. Sibley, University of Guelph / School of Environmental Sciences*

Concerns about the effects of neonicotinoid pesticides to non-target organisms have been mounting based on evidence of impacts on pollinators. Soil invertebrates such as earthworms are also susceptible to neonicotinoid exposure due to potentially extensive neonicotinoid residence times in soil and the likelihood of multiple applications per growing season. Standardized testing has contributed the development of baseline toxicological data for many of the standard species, including the earthworm *Eisenia andrei*. While sensitivity has been well-documented, measured environmental concentrations of neonicotinoid insecticides in soil are significantly lower than those known to cause adverse reproductive effects in this species. In these studies, we hope to account for both the potentially long duration of neonicotinoid residence in agricultural soils and low concentrations at which they have been detected by exposing one parental and three successive filial generations of *E. andrei* to single applications of the neonicotinoids Thiamethoxam and Clothianidin in an Ontario agricultural soil.

**RP024 Pyrethroid concentrations toxic to *Hyalella azteca* in an urban creek diluted to non-toxic levels by municipal wastewater discharge**

*P. Bedore, M. Bryan, Robertson-Bryan Inc; C.A. Irvine, RBI / Ecosystem Services*

Waterways in California's Central Valley have been determined to be impaired due to toxicity from pyrethroids. This has spurred California's Regional Water Quality Control Boards to promulgate regulations to address discharge of pyrethroids from agriculture, urban stormwater, and municipal wastewater sources. Many municipal wastewater treatment plants (WWTPs) in California utilize tertiary-level treatment. Often this high level of treatment is capable of meeting water quality objectives/criteria end-of-pipe, which is desirable when the receiving water is dominated by the effluent discharge, even though there can be other pollutant sources in the watershed. We conducted a year-long study to evaluate pyrethroid levels and toxicity in Central Valley creeks receiving effluent discharges from two California tertiary WWTPs. For both sites, water samples were collected from the discharge, upstream, and downstream creek stations for pyrethroid chemical analysis (detection limits as low as 5 pg/L). Effluent and creek samples for one site were also tested for acute toxicity with the crustacean, *Hyalella azteca*, a species sensitive to pyrethroid toxicity. Results demonstrate that tertiary-level treatment of municipal wastewater provides high pyrethroid removal efficiencies and that pyrethroid levels in the treated effluent were low and not toxic to *H. azteca*. The highest pyrethroid concentrations and the sole instance of toxicity were observed at an upstream creek station. This occurred during a first-flush rain event where the predominant land use is urban-residential. Dilution of upstream creek water by the WWTP's effluent discharge resulted in non-toxic conditions downstream during the same first-flush rain event. The study demonstrates that discharge of tertiary-treated WWTP effluent to surface waterbodies, although often considered a stressor itself, can benefit downstream water quality through high constituent removal efficiencies which can facilitate diluting upstream non-point sources of pollutants.

**RP025 Where is the biology in terrestrial vertebrate pesticide risk assessments?**

*C. Habig, Compliance Services International*

The EPA evaluates potential risks to birds and mammals using its T-REX model. T-REX is an intentionally conservative screening-level spreadsheet model with a low number of user inputs that estimates potential exposure and risks to birds and mammals through ingestion of feed items containing pesticide residues. The model includes five generic categories of feed items – short grass, tall grass, broadleaf plants, arthropods, and seeds, pods, and fruits. Upper-end pesticide residues are estimated for each of these feed item categories based on the Fletcher et al modifications to the Hoerger and Kenaga nomogram. These residue estimates are paired with toxicity values for the compound being evaluated, and the model then calculates acute and chronic risk quotients (RQs). To pass, acute RQs for non-endangered species need to be < 0.5, while acute RQs for endangered species need to be < 0.1. Chronic (or longer-term) RQs need to be < 1.0 to pass. If a product fails the T-REX assessment, what are the options for refinement of the assessment? Options for quantitative refinement are often minimal, and typically focus on evaluating possible options for changes to the use pattern or use scenario. These changes may include changes to the maximum application rate, the number of applications in a season, the interval between applications, and, if data are available, the foliar dissipation rate. However, qualitative refinements that focus on biological attributes of key species of concern are also feasible, but are often overlooked. These types of considerations include factors such as more detailed analysis of the types of food ingested (preferred foods), behavioral aspects such as how animals primarily forage for food (e.g., a ground forager, foraging on flying insects, foraging on soil invertebrates), as well as a species' preferred habitat. These considerations are particularly useful when evaluating potential effects on endangered species that may be found near agricultural use sites. Examples of the impacts of these more in-depth considerations will be provided for a) a product that is soil incorporated; and b) species that forage on flying insects around treated areas.

**RP026 Wild bees and pesticides: Reported applications compared to detections in multiple matrices in an intensively managed agricultural landscape**

*L.T. Ward, University of California, Berkeley / Department of Environmental Science, Policy, and Management; M.L. Hladik, M.D. De Parsia, USGS / California Water Science Center; C. Kremen, N.J. Mills, University of California, Berkeley / Department of Environmental Science, Policy, and Management*

To better understand the exposure of wild bees to pesticides in an agricultural landscape, samples were collected from fields in northern California. Hedgerows are known to provide habitat for wild bees, but these bees may also be exposed to pesticides from nearby agricultural fields. The current study targeted eight hedgerow sites located in an intensively managed agricultural landscape that includes almonds, (wine) grapes, rice, tomatoes, and walnuts. In addition to collecting both wild bees and honey bees, soil, flowers, and silicone passive sampling devices (PSD; staked near the hedgerows to sample the air) were also included. Sampling was conducted from April to June 2016, to coincide with peak bloom and bee activity. Samples were analyzed for >150 pesticides and degradates using both gas and liquid chromatography-tandem mass spectrometry. Overall, 38 pesticides were detected in all matrices (10 insecticides and degradates, 12 fungicides, 15 herbicides and degradates, and 1 plant growth regulator). The number and type of pesticides detected varied by matrix; 24 compounds were detected in the PSDs, 24 in soil, 15 in flowers, 18 in wild bees, and 10 in honey bees. Pesticide application information for the locations and sampling time frames were compared to the detections. These results can help determine which matrices are best at estimating wild bee pesticide exposure and which pesticides should be targeted for future effects work.

**RP027 Organosilicon adjuvants in pollen: Initial results from a 2018 field survey**

*A. Slade, W.J. Doucette, Utah State University / Utah Water Research Laboratory; D. Cox-Foster, USDA / ARS-PWA / Pollinating Insect Research Unit*

Adjuvants are chemicals that are added to enhance the performance of the active ingredient(s) in pesticide products. Trisiloxane surfactants (TSS) are an important class of adjuvants used in various pesticide spray applications. Commercial TSS products are oligomer mixtures typically consisting of a hydrophobic trisiloxane backbone with various hydrophilic side chains composed of ethylene and propylene oxide (EO/PO) units capped with acetoxy, hydroxy, and methoxy end groups. These TSS surfactants have been identified in pollen, beeswax, and honey, and recent studies report that TSS surfactants can impair honey bee learning and interact synergistically with viral infections in honey bee larvae. As part of a larger study, designed to examine the impact of TSS on honeybees, we examined the extent of TSS contamination in pollen samples collected by various beekeepers from hives located in California and Kentucky during February and March 2018. Pollen samples were extracted with acetonitrile and analyzed by high performance liquid chromatography coupled to a triple-quadrupole mass spectrometer (LCMS-QQQ). Limits of quantitation (LOQ) for the acetoxy, hydroxy, and methoxy-capped trisiloxanes oligomers were 1.18-10.58ng/g, 0.18-7.05ng/g, and 0.29-2.94ng/g, respectively. In the 27 samples analyzed to date, hydroxy-capped trisiloxanes were found in over half the samples with concentrations in the low ng/g levels for the sum of all hydroxy oligomers (oligomers n = 6-8 were the most commonly found). Little to no acetoxy and methoxy-capped trisiloxanes have been found above the LOQs so far. However, it should be noted that recoveries of TSS added to clean pollen sent to the field and back were much lower than freshly spiked pollen. Additional extraction and clean up methods are being evaluated. A preliminary pesticide screening analysis for over 60 pesticides was also performed on each sample using gas chromatography-mass spectrometry. To date, three fungicides have been tentatively identified: cyprodinil, pyrimethanil, and propiconazole.

**RP028 Estimating Neonicotinoid Residues in Pollinator-Attractive Habitat by LC-MS/MS Analysis**

*M.J. Hall, Iowa State University / Entomology; V. Dang, Iowa State University / Veterinary Diagnostic Laboratory; G. Zhang, Iowa State University / Entomology; D. Borts, Iowa State University / Veterinary Diagnostic Laboratory; S.P. Bradbury, Iowa State University / Natural Resource Ecology and Management; J.R. Coats, Iowa State University / Entomology*

Recent research has suggested that neonicotinoid insecticides applied to crops can be detected in adjacent pollinator-attractive habitats and pollen collected by honey bees. Honey bees, native bees, and monarch butterfly larvae could be exposed to neonicotinoids through contact with or ingestion of contaminated pollen, nectar, and milkweed leaves. Although these studies indicate that neonicotinoids can be detected in pollinator-attractive habitats, the magnitude and extent of potential adverse effects to honey bees, native bees and monarch larvae is an active area of research. In this study, we developed and validated an innovative method to simultaneously evaluate concentrations of clothianidin, imidacloprid, and thiamethoxam, and two imidacloprid metabolites (5-hydroxy imidacloprid and imidacloprid olefin) in plant foliage. The results indicate that we have acceptable ranges for the recovery, low and high quality control (between 75% and 110%), while the testing for a matrix effect indicates minimal ion suppression or ion enhancement for all analytes. The calibration curves were linear over the concentration ranges with $r^2$ at > 0.998.The data obtained established a validated, single extraction and LC-MS/MS analytical method for quantifying neonicotinoid concentrations to a method detection limit of 0.04 to 0.3 ng/g plant material. This method is comparable, or in some cases better than, existing methods that require separate extraction and/or LC-MS/MS methods. We are using the method to analyze leaf and pollen samples collected in 2017 and 2018 from habitat patches adjacent to corn and soybean fields planted with neonicotinoid-treated seeds. This data will provide insights on spatio-temporal variability of neonicotinoid concentrations in Midwestern agroecosystems and help inform pollinator risk assessments.

**RP029 A Novel System to Study the Effects of Agrochemicals on Honey Bee Queen Health and Fecundity**

*J. Fine, University of Illinois / Carl R. Woese Institute for Genomic Biology; G.E. Robinson, University of Illinois at Urbana Champaign / Institute for Genomic Biology*

As the sole producer of fertilized eggs in a colony, honey bee queen health and reproduction are essential to the longevity of a colony. Recent research has demonstrated negative effects of agrochemicals on colony reproduction, including decreased colony expansion, queen failure and replacement, and decreased queen egg laying. This suggests that agrochemicals can have negative effects on queens as well as workers. However, it is much more difficult to quantify the performance of queens relative to workers in the field, and there are no laboratory assays for queen performance. This presentation will describe a new system developed to study the effects of numerous stressors on honey bee queen egg laying under tightly controlled, laboratory conditions using custom designed Queen Monitoring Cages (QMCs), yielding a quantitative endpoint. The results of the first experiment in this system examining the effects of imidacloprid administered in worker diet on queen egg laying will be described, and the results will be compared to previous work in full sized colonies exposed to dietary imidacloprid. Additionally, queen retinue behavior will be quantitatively assessed in workers following chronic exposure to imidacloprid to determine if imidacloprid affects this behavior. Taken together, the results of these experiments will provide insight into the sociotoxicology of agrochemicals in honey bee colonies and the consequences to queen fecundity. Furthermore, these experiments will provide a framework that can be used to study other potential stressors and their impacts on colony health, including pathogens, parasites, poor nutrition, and interactions between them in a more controlled context.

**RP030 Effects of neonicotinoid insecticides on hummingbirds**

*N. Sandoval Herrera, University of Toronto, Scarborough / Ecology and Evolutionary Biology; C.A. Bishop, Environment and Climate Change Canada / Wildlife Research Division; J.E. Elliott, Environment and Climate Change Canada / Science and Technology Branch Ecotoxicology and Wildlife Health Division; K.C. Welch, University of Toronto, Scarborough / Biological Sciences*

Neonicotinoids are neurotoxic systemic insecticides that have become the most widely used group of insecticides worldwide. These compounds affect the nervous system, interfering with the transmission of nerve impulses and impairing vital physiological processes. There is a growing concern about their environmental impacts, particularly linked to bee colony collapse disorder and drastic reductions in insect populations. While the loss of pollination services provided by bees to ecosystems and agriculture has been widely studied, the neonicotinoid effects in other pollinators such as hummingbirds haven't been assessed yet. Hummingbirds in particular present a great risk of exposure to pesticides due to their high daily nectar intake, making them also more vulnerable to the adverse effects of these toxic substances. We examined the sublethal toxic effects of the neonicotinoid imidacloprid in captive Ruby-throated hummingbirds (*Archilochus colubris*). Using a multibiomarker approach we evaluated biochemical, physiological and behavioral impairments. Two doses were tested, a high dose based on previous toxicity assessments in similar size species and a low dose calculated from the potential daily consumption of imidacloprid by hummingbirds feeding in blueberry crops. To determine cellular neurotoxic effects, Cholinesterase activity and oxidative stress response were measured. As physiological response Resting Metabolic Rate and immune function were examined. Likewise, the toxicokinetics of the insecticide were assessed through urine analyses. This is the first study assessing the effect of pesticides in hummingbirds, our results will provide insights of pesticide exposure as a potential threat for populations of these species and will help management agencies improve regulation.

**RP031 Further developments of a passerine model of subacute neonicotinoid toxicity using zebra finches**

*E. Hofmeister, USGS / Biological Resources Division; J.S. Lankton, USGS / National Wildlife Health Center; M.D. Jankowski, USEPA / Office of Environmental Review and Assessment / Region 10*

Neonicotinoid insecticides are nicotinic acetylcholine receptor (nAchR) agonists commonly used in agriculture as seed coatings. While these compounds were developed to be insect nAchR specific, population declines of wild birds have been attributed to these chemicals, and behavioral, reproductive, and lethal effects have been experimentally documented in laboratory-exposed birds. Our goal is to develop a model of subacute neonicotinoid (clothianidin (CTD)) toxicity in an altricial passerine (zebra finches (*Taeniopygia guttata*)). In a series of studies differing mainly by exposure duration and medium, we first determined an acute effects concentration of CTD by treating fasted birds with coated millet seed (CTD treatments range, 15 – 1000 mg/kg bw). Above 125 mg/kg bw (males) and > 60 mg/kg bw (females), we observed strong refusal of coated seed. At these treatment levels, birds consumed approximately 2.0 – 0.26 mg CTD / bird. Within 2 hr after treatment with 125 mg/kg we observed inactivity, fluffed feathers, respiratory difficulty, and, in some cases, inability to fly. Based on these results, we estimate the NOAEL and the LOAEL for our study to be 15 and 30 mg/kg bw, respectively. We next exposed birds for 7 days to CTD in drinking water at nominal doses of 8.6, 4.3, 2.2, and 0 mg/kg (cumulative 60, 30, 15, and 0 mg/kg CTD). Clinical signs of toxicity were not observed in any bird. Lastly, birds were gavaged daily for 7 days with 18 mg/kg bw dissolved in acetone and mixed with vegetable oil. Clinical signs of toxicity were observed beginning after the fourth exposure day and were similar to signs observed in acute (125 mg/kg) CTD dosing. The birds were video recorded at the same time each afternoon and activity was quantified. Generally, behavior returned to normal each day 6-8 h after dosing with CTD. At 14 days following either the single acute dose or the final dose in the subacute study, all birds were euthanized and histopathology was performed on liver tissue and brain acetylcholinesterase (AChE) level determined. In birds dosed for 7 days, lesions were not observed in liver tissue and the AChE activity was normal. Our work provides further information on experimental exposure strategies for a model passerine and helps to set the range of CTD that might be used in a subacute or chronic toxicity trial in zebra finches.

**RP032 Use of dermal absorption data for estimating avian dermal LD50s and dermal exposure in higher-tier risk assessment models for pesticides**

*J.D. Maul, Syngenta Crop Protection / Environmental Safety; C. Blackstock, Charles River Laboratories Edinburgh; R. Brain, Syngenta Crop Protection, Inc. / Environmental Safety*

Estimating avian exposure via a dermal pathway is essential for higher-tier ecological risk assessments (ERA). However, dermal exposure and toxicity data for birds are seldom available. The USEPA's higher-tier Terrestrial Investigation Model (TIM) uses a method to estimate avian dermal LD50 values and dermal exposure that for some compounds results in estimates of high dermal exposure and low dermal LD50 values. This pattern is likely attributable to using organophosphate and carbamate toxicity data to develop the oral-dermal relationship (i.e., an estimated dermal LD50 is necessary to generate a dermal route equivalency factor that normalizes potency relative to oral toxicity within TIM's dermal pathway dose equation). However, use of these relationships may introduce uncertainty into ERAs when extrapolated to other classes of chemistry. In this study, atrazine dermal absorption experiments were conducted with mallard, northern bobwhite, and rat skin. These data were used to derive an avian-mammal dermal route equivalency factor for atrazine and introduce an alternative approach for estimating dermal LD50 values and predicting exposure via the TIM dermal pathway. Compared to the default TIM method, use of measured rather than modeled data yielded TIM output with lower mean total dose, lower dermal fraction of total dose, greater oral fraction of total dose, and reduced model predicted mortality for atrazine. In addition, the new approach was compared with other methods for estimating avian dermal LD50 values, such as those proposed for use with mammalian data and physico-chemical properties. Ultimately, these comparisons demonstrated that the use of dermal route equivalency factor derived from empirical data provided estimates of avian dermal LD50 values that were markedly higher than those from model-based estimates. Consequently, use of dermal route equivalency factors based on atrazine-specific empirically derived data reduced predicted risk relative to those using default TIM model assumptions.

**RP033 Bird Survey Data Indicates No Negative Impact of Neonicotinoid Use**

*S.P. McGee, Bayer CropScience LP / Environmental Health Sciences; C. Hassinger, Bayer CropScience LP; D. Fischer, Bayer CropScience LP / R&D / Environmental Safety*

Neonicotinoids are currently one of the most widely used insecticide clasess. Although the risks to birds were evaluated and found to be acceptable by North American regulatory authorities when these products were first registered in the mid 1990's and early 2000's, it has recently been hypothesized that neonicotinoids may be having unforeseen adverse effects on avian populations, in particular on seed-eating and aerial insectivorous species. We assessed data from the North American Breeding Bird Survey (BBS) and the Iowa Breeding Bird Atlas (IBBA) to determine if there is evidence of direct (lethal or sublethal effects) or indirect (food chain disruption) impacts on these species. These data sets provide real-world observations of status and trends for avian species in landscapes where neonicotinoid use was formerly non-existent, but is now extensive. To determine if spatial or temporal population trends for aerial insectivore or seed-eating birds have been impacted, hierarchical models were fit to BBS data. In regions of high neonicotinoid use (*e.g.*, Prairie Pothole and Midwest Corn Belt), population trajectory for these species generally increased after the introduction of neonicotinoids. Analysis of data from individual BBS routes revealed no association between bird count data and percent of land area in crops receiving neonicotinoid treatment. Iowa has a high percentage of land area in crops receiving neonicotinoid applications. The IBBA provides data on the presence of bird species in "blocks" of land measuring 3 miles by 3 miles each that are systematically located across the state. Comparison of IBBA data for the years 1985-1990, before neonicotinoids were used, and 2008-2012, after neonicotinoids became widely used, revealed an increase in the % of blocks occupied after neonicotinoid use for 10 out of 11 species of aerial insectivorous and seed-eating species. The results of these analyses consistently found no evidence to support the hypothesis that widespread adoption of neonicotinoid insecticides has resulted in negative impacts on bird populations. If anything, bird population trajectories have increased since neonicotinoids were introduced.

## Assessing Contaminant Effects in Ecosystems with Multiple Stressors with a Focus on the California Bay-Delta

**RP034 Sediment Characteristics and Fluridone Concentrations: Building Upon Methods to Enhance Delta Smelt Habitat**

*S.A. Lesmeister, State of California / Department of Water Resources / Division of Environmental Services; K. Hoffman, California Department of Water Resources / Division of Environmental Services; J. Caudill, California State Parks / Division of Boating and Waterways; P. Pandey, University of California, Davis; L. Conrad, California Department of Water Resources / Division of Environmental Services*

The spread of the invasive aquatic plant, *Egeria densa*, in the San Francisco Bay-Delta has impaired water quality and habitat for the endangered Delta smelt, *Hypomesus transpacificus*. As part of the Delta Smelt Resiliency Strategy, the California Department of Water Resources partnered with California Department of Parks and Recreation, Division of Boating and Waterways (DBW) to determine if herbicide application could help improve degraded habitats of Delta Smelt. Since 2001 DBW has applied herbicides, including fluridone, to reduce the density and spread of *E. densa* and other aquatic invasive plants. Existing monitoring measures fluridone concentrations in water, but the primary route through which *E. densa* uptake fluridone is through the roots. We predict sediment fluridone concentrations will be greater than water concentrations and that sediment characteristics will affect flurdione concentrations. From October 2017 through June 2018, we measured fluridone concentrations and sediment characteristics at three sites: two treated sites (Decker Island and Little Hastings Tract) and one non-treated (French Island) in the northern region of the Bay-Delta. Fluridone concentrations were significantly greater in the sediment than in the water at both treated sites. Fluridone concentrations ranged from non-detect to 93 µg/L in sediment, compared to non-detect to 6.60 µg/L in water. Decker Island, located in the Sacramento River, had significantly lower organic content than French Island and Little Hastings Tract. Over fifty percent of the sediment composition ranged in size from 5 and 7.5µm , with less than 15% of the sediment being less than 1 µm. Results from this study will help inform aquatic invasive plant control programs using fluridone enhance the effectiveness of *Egeria* management in the San Francisco Bay-Delta.

**RP035 From algal toxins to environmental DNA: Passive samplers as a tool to help with multiple management objectives**

*E. Preece, M. Bryan, Robertson-Bryan, Inc.*

Climate changes are expected to affect water-quality, ecosystem health, and species viability within the San Francisco Bay-Delta (Delta). As these changes occur, it will be necessary to streamline data collection protocols so that sampling tools can simultaneously address multiple management objectives while saving time and money. One currently used tool that shows promise for meeting multiple management objectives are Solid Phase Adsorption Tracking (SPATT) samplers. SPATTs were developed as an economical tool to passively monitor algal toxins that may be missed by discrete grab sampling. SPATT's have proven useful in the Delta and will continue to be used to monitor future algal toxins. We found SPATTs can also be used to monitor for Environmental DNA (eDNA). The eDNA method is an efficient, non-invasive, and relatively rapid process that can determine species presence and organism occupancy. Typically, eDNA monitoring involves collecting a discrete grab sample. However, traditional sampling methods may limit the spatial and temporal scale of eDNA monitoring. In a pilot study, we used SPATT and grab samples to determine if imperiled freshwater mussels (Unionidae) were present in the Delta. We deployed six SPATTs at two Delta locations. *Anodonta Californiensis* were detected in all six SPATT samples and 33 grab samples in the San Joaquin River near Mossdale. No mussel eDNA was detected in any SPATT samples at the I street bridge, but *A. Californiensis* was detected in 2 of 11 grab samples. This is the first time we are aware that SPATT samplers have been used to monitor for eDNA. Although we successfully used SPATTs, additional eDNA investigations and modification of the method may further improve upon our results. We believe this is a promising tool to meet future management objectives by cost effectively detecting cryptic species such as Delta Smelt, while simultaneously monitoring for algal toxins.

**RP036 Networks of Disturbance of Midwestern United States Streams**

*T.S. Schmidt, USGS / Colorado Water Science Center; D. Carlisle, P.C. Van Metre, USGS*

The National Water Quality Assessment Project (US Geological Survey) surveys streams in different eco-regions to better understand how land use practices affect water quality and ecological integrity. In the summer of 2013, 100 streams in the Midwestern US were sampled. Several modeling approaches (e.g., CART, BRT, and Quantile Regression) were previously employed to filter over 2000 indicators (e.g., GIS variables, water and sediment chemistry, and habitat) of ecological condition. Through this empirical process we identified fifteen indicators that were important to stream condition. Employing watershed theory, we developed a structural equation model (SEM) of how these indicators were inter-related. Then using SEM, we fit this “disturbance network” to multimetrics of algae, invertebrate, and fish community integrity removing any indicators otherwise not related to the ecological responses. Six of the fifteen indicators—agricultural and urban land uses, sand content of watershed soils, riparian forest area, soil eroded into the stream, and relative bed stability—were important to all three-community metrics. The algae (riparian cover, temperature, phosphous, total triazine) and invertebrate (nitrogen, ammonia, pyrethroid degradates in water, bifenthrin in sediment) models included unique variables not included in the fish model. Although all three landscape indicators were important predictors of all the ecological communities, agricultural (algae), urban (invertebrates), sand content of watershed soils (fish) were most strongly related. Ecological integrity of midwestern streams is affected by both agricultural and, surprisingly, urban land uses. Synthetic chemicals related to crops (pesticides and nutrients) and residential uses (pyrethroids) are more strongly related with ecological integrity than natural factors (riparian forest, watershed soil character), however, these natural factors are important to the ecological integrity of streams despite the prevalence of intense agricultural land use in the midwestern US.

## Environmental Mercury Exposure: Mechanisms Associated with Its Immediate and Generational Effects

### RP038 Mercury concentrations in subsistence foods from Lake Atitlán, Guatemala

*R. Jordan, Northern Arizona University / Biology; F.A. von Hippel, Northern Arizona University / Department of Biological Sciences; S. Chandra, University of Nevada Reno / Global Water Center and Biology Department; E. Rejmankova, University of Califorina, Davis / Environmental Science and Policy; B. Hagedorn, University of Alaska, Anchorage / Department of Chemistry; H. Villavicencio, University of Alaska, Anchorage / Department of Biological Sciences*

Lake Atitlán, the deepest lake in Central America, is a crucial source of subsistence foods and supports productive agricultural systems. Anthropogenic contamination has accelerated in recent decades due to untreated wastewater discharge and fertilizer runoff that enters the lake. Elevated concentrations of heavy metals, including mercury (Hg), may pose a health risk to local wildlife and the 250,000 inhabitants of the Lake Atitlán watershed. Hg is a neurotoxic metal that disrupts normal reproductive and neurological function in humans. Hg has the potential to bioaccumulate and biomagnify within the food web, posing additional risks to the Lake Atitlán community. This study aims to estimate current Hg levels in important subsistence foods (fish, snails, and crabs). Samples were collected from the Santiago market that sells Lake Atitlán catch for human consumption. Hg levels in muscle tissue from each organism are analyzed using the PerkinElmer FIMS 100 Flow Injector Hg system. Tissue samples are freeze dried, digested using hydrochloric acid, filtered, and analyzed for Hg content. High detectable Hg levels in these organisms may exceed the EPA guidelines for safe Hg consumption. These results will indicate if heavy metal contamination in the watershed has resulted in elevated concentrations in local wildlife and food sources that support a diverse group of Mayan cultures.

### RP039 Role of natural organic matter in regulating the toxicity of MeHg in embryonic Zebrafish

*D. Li, University of Chinese Academy of Sciences; H. Lin, L. Guo, M.J. Carvan, University of Wisconsin, Milwaukee / School of Freshwater Sciences*

Dissolved organic matter (DOM) occurs ubiquitously in aquatic environments and plays important roles in regulating the solubility and chemical speciation of metals and thus their fate, transport, bioavailability and toxicity. Over the past decades, the toxicity, bioaccumulation and biomagnification of mercury (Hg), including inorganic Hg and methylmercury (MeHg), have been extensively studied in many aquatic organisms. However, interactions between natural DOM and metals, and changes in metals chemical speciation and toxicity, remain poorly understood. In this study, we have examined the mitigation effects of natural and model DOMs on the toxicity of Me-Hg in embryonic zebrafish. Five model DOM with different functionalities, including thiosalicylic acid (TA containing aromatic thiol), dextran (DX, a disaccharide), alginic acid sodium salt (AAS, polysaccharide with –COOH), L-glutathion (GSH, peptide with thiol), and humic acid (HA), and three natural organic matter (NOM) samples, including Suwanne River NOM, Yukon River NOM and Mississippi River NOM, were used to elucidate the role of DOM quantity and quality in mitigating Me-Hg toxicity. The embryonic Zebrafish (< 4 hpf) were exposed in media with DOM (at 0, 1, 3, 10, 30 and 100 mg-C/L, respectively) and MeHg (at 0 and 300 nmol-Hg/L) for 24 h. After the initial exposure, the embryos were then exposed in medias with DOM without MeHg. Hatching, mortality and deformation at 24, 48, 72 and 96 h were recorded. The results showed that the mortality of embryos exposed in the MeHg was up to 30% at 24 h, and deformations at 72 and 96 h were almost 100%. Main deformations were brain and tail, followed with axis, face, eye and cardiac edema. With increasing concentrations of DOM (except for DX), the extent of deformations on the axis and tail was mitigated. The deformation of larvae exposed to AAS decreased with increasing DOC concentration (from 98% to 27% at 72 h and from 90% to 29% at 96 h). In addition, the GSH and TA at the concentration of 10 ppm and 1 ppm-DOC could effectively alleviate the toxicity of MeHg at 72 h, 3 ppm for GSH and 1 ppm for TA at 96 h. Three NOM also mitigated the toxicity of MeHg on the embryonic Zebrafish. Therefore, our results demonstrated that natural DOMs with different functional groups could effectively mitigate, to various extents, the toxicity of MeHg in the zebrafish, with thiosalicylic acid containing aromatic thiols being the most effective to alleviate the deformation of fish.

### RP040 The use of lichen as a bioindicator of atmospheric monomethylmercury deposition in coastal California

*P. Weiss-Penzias, University of California, Santa Cruz / Microbiology and Environmental Toxicology; B. Zheng, University of California, Santa Cruz / Chemistry and Biochemistry; W. Lin, University of California, Santa Cruz / Biology*

Monomethylmercury (MMHg) is a potent neurotoxin that bioaccumulates in food webs and was recently discovered to be present in marine fog and stratus clouds on the coast of California due to the oceanic evasion of a volatile precursor compound called dimethylmercury. The goal of this project was to determine if a commonly-found species of lichen (Ramalina menziesii) could serve as a bioindicator of atmospheric MMHg and total Hg (THg) deposition in coastal California. For this project, 29 Ramalina menziesii samples from 14 different state and county parks located 0-60 km inland from the ocean, were collected, freeze-dried and homogenized, then analyzed for MMHg and THg concentrations. The THg concentrations ranged from 49.5 to 1353.6 ng g-1, with an average of 227.4 ± 251 ng g-1. The MMHg concentrations ranged from 3.5 ng g-1 to 65.2 ng g-1, with an average of 19.6 ± 15 ng g-1. Average MMHg concentration for lichen from each site increased significantly with the fog and low cloud cover (hours/day) at each site (ANOVA, p= 0.0004), as determined from literature data. The sites located 0-10 km to the ocean had a mean MMHg concentration that was 3.7 times higher than the sites located 30-60 km from the ocean. These data suggest that lichen is a good indicator of airborne mercury concentrations and that some species, like Ramalina, which are eaten by deer and other animals, could expose higher trophic animals like mountain lions to unsafe levels of Hg in their diets.

**RP041 Mercury Concentrations and Seafood Mislabeling in Sashimi Purchased in Central Texas**

*M. McCormack, Texas State University, San Marcos / Biology; S. Harding, T. Gold Quiros, S. Britton, D. Rodriguez, J. Dutton, Texas State University / Department of Biology*

Sushi consumption in the U.S. has grown significantly and while providing many important health benefits, sushi including sashimi, can be a significant source of mercury (Hg) to humans. Seafood mislabeling, which can potentially expose consumers to elevated levels of Hg, makes assessing the risks and rewards of seafood consumption even more complex. The objective of this study was to 1) determine the concentration of Hg in sashimi [tuna, albacore, white/super white tuna, salmon, red snapper, yellowtail, Japanese snapper, octopus, squid, and roe (salmon and sea urchin)] purchased from restaurants in Central Texas using a direct mercury analyzer, and 2) genetically identify the species used in sashimi using DNA barcoding. Mean Hg concentrations, based on restaurant menu items, was highest in white/super white tuna, Japanese snapper, and tuna (0.968, 0.595, and 0.539 µg/g wet wt respectively), and lowest in squid, salmon, sea urchin roe and salmon roe (0.022, 0.022, 0.005, and 0.002 µg/g wet wt, respectively). 46% and 14% of white/super white tuna and tuna samples, respectively, exceeded the 1 µg/g wet wt Food and Drug Administration (FDA) action level. The variability in Hg concentration for a given type of sashimi could be due to differences in body length/age, harvesting location, trophic level and mislabeling, which makes assessing the potential risk of sashimi consumption difficult. Of the 115 samples which could be genetically identified, 48% were mislabeled; 100% of white/super white tuna, red snapper, Japanese snapper, yellowtail, and squid were mislabeled, whereas tuna, salmon, octopus and roe were all correctly labeled. Mislabeling resulted in sashimi samples having Hg concentrations that did not correspond to expected values based on menu listings. Red snapper for example was identified as either Mozambique tilapia or red seabream, which resulted in samples having a lower Hg concentration than what was expected. In comparison, white/super white tuna was actually escolar which resulted in a higher than expected Hg concentration. High instances of seafood mislabeling across a variety of sashimi types, such as those reported in the present study, are concerning and warrant further study.

**RP042 Selenium Availability in Freshwater Fish is Inversely Related to Methylmercury Bioaccumulation and Toxicity**

*N. Ralston, Sage Green NRG / Earth Systems Science and Policy; L. Raymond, Translational Medicine Independent Research Consultants*

Based on the biochemical mechanisms of mercury (Hg) toxicity, concomitant assessments of selenium (Se) intakes are required for reliable assessments of risks potentially associated with Hg exposures. This consideration is especially true in regions that are Se-poor or exposed to high Hg inputs. In particular, subsistence consumers of high methyl-Hg ($CH_4Hg^+$), low-Se freshwater fish may be at greater risk than would have been assumed based on earlier assumptions that did not consider Hg's biochemical mechanisms of toxicity. Because $CH_4Hg^+$ is uniquely able to: 1) diminish maternal Se redistribution across the placental barrier, 2) decrease Se-transport across the blood-brain barrier, and 3) irreversibly inhibit selenoenzyme activities which are required to prevent and reverse oxidative damage in brain tissues, Se status is a pivotal consideration in $CH_4Hg^+$ risk assessments. The Hg and Se content data of ~5,000 freshwater fish from North American watersheds were compiled for calculation of their Health Benefit Values (HBVs). There was a strong inverse relationship between environmental Se availability and $CH_4Hg^+$ contents of the fish, especially among aquatic apex predators. Due to the high binding affinities between Hg and Se, the same chemical reactions responsible for the irreversible inhibition of Se-dependent enzymes, formation of insoluble HgSe, and the physiological consequences of high $CH_4Hg^+$ exposures were predicted to result in an inverse relationship between Hg and environmental Se availability. In the presence of adequate Se, Hg that is retired as HgSe cannot bioaccumulate in aquatic food webs. However, in the absence of adequate Se, there is no Hg retirement, and increased $CH_4Hg^+$ bioaccumulation should occur. This study found the highest fish Hg concentrations were observed in watersheds with the poorest Se availability. Although increased exposure from eating such fish will increase risk, the fact that Se-poor consumers will be more vulnerable to the effects of high $CH_4Hg^+$ exposures accentuate the risks of adverse effects. Thus, increased $CH_4Hg^+$ exposures in areas where environmental Se is poorly available may result in an adverse synergy with the potential to cause far greater impairments to fetal neurodevelopment than those predicted by earlier $CH_4Hg^+$ risk assessment criteria. Increased monitoring is required to identify regions that are likely to have subsistence populations at risk.

## Plants in Environmental Risk Assessment: Assessing and Predicting the Effects of Chemicals on Plant Communities

**RP043 Determining the size effect that can be estimated from a NTTP Study**

*J.W. Green, DuPont / Data Science and Informatics*

Regulatory requirements in the EU and US on the size effect to be estimated for responses (growth and percent emergence) from guideline non-target terrestrial plant (NTTP) studies are under review. Such studies are conducted primarily to determine whether crop protection chemicals meant to protect a specific crop might cause harm to other plant species that are unintentionally exposed, such as through spray drift. Crop Life America investigated a large database of such studies from testing facilities across the world with the aim of determining what regulatory requirements are justifiable and consistent with data routinely collected in such studies. One issue investigated was for what values of p is it reasonable to require the estimation of a p% effects rate (ERp) for growth and shoot height measurements for regulatory risk assessment. To address the question, seven regression models were attempted to be fit to both responses from vegetative vigor and seedling emergence studies in the database and the quality of the models were assessed using well-defined objective criteria (Green *et al.* 2018). The best model was selected for each response and ECx estimates were assessed for x=5 to 50 from that model. This allowed an assessment of the size effect that can reasonably be expected for these responses and study types. Models investigated are those recommended in OECD guidance (OECD 2014) on statistical analysis of ecotoxicity studies and have a long history of use in numerous NTTP studies. These are the Bruce-Versteeg, Brain-Cousens hormetic, 3-parameter log-logistic, and a suite of 2-4 parameter exponential models. There were 89 studies, and approximately 10 plant species tested per study and 2 responses per plant, so well over 10,000 regressions evaluated. The results of this study provide a robust guide to the size effect can be estimated under a variety of conditions regarding dose-response shape, maximum observed effect, and experimental design. In addition, model selection and estimate assessment criteria went through a rigorous test and specific recommendations are provided.

**RP044 Hydroponic uptake and distribution of PPCPs in *Typha lafitolia* and *Zea mays*: A comparative study in two monocotyledon model plants**

*D.J. Perez, INTA / Agronomy; W.J. Doucette, Utah State University / Utah Water Research Laboratory; M. Menone, Universidad Nacional Mar del Plata / Lab de Ecotoxicologia*

Pharmaceuticals and personal care products (PPCPs), originating from wastewater treatment plants, have been detected in reclaimed waters and aquatic ecosystems potentially resulting in the accumulation of PPCPs in wetland plants and terrestrial crops. The objective of this study is to investigate the root uptake, translocation and distribution of a mixture of PPCPs and the herbicide atrazine, in two monocotyledon plants, one wetland plant *Typha latifolia* and one terrestrial plant *Zea mays*. The target PPCPs included antibiotics (sulfamethoxazole (SMZ) and triclosan

(TRI)), an anticonvulsant (carbamazepine (CBZ)), an antidepressant (fluoxetine (FLX)), and an antihyperlipidemic (gemfibrozil (GBZ)). Atrazine (ATZ) was also selected as a herbicide commonly used on corn. Twelve size uniform plants of each specie were selected for the hydroponic exposure assay. Six plants were used as untreated controls and six were treated. A single dose was added to the hydroponic containers to yield an initial concentration of 20 µg/L for each compound. Transpiration was measured by water lost in the root-zone vessels relative to a non-planted control. The root zone solution was replenished weekly with a nutrient solution containing 20 µg/L of the target compounds. For *T.latifolia,* root, rhizome, sprout, stem and leaf (base, middle and tip) tissues were collected and analysed while root, stem, base and top leaves and bud flowers were examined for *Z.mays*. Sample extracts were analysed using liquid chromatography coupled to a tandem mass spectrometer. All target compounds were detected in the roots of both plants. Above ground tissue concentrations were normalized to the amount of water transpired. For *T. latifolia,* only PPCPs and ATZ were found in the stems while the distribution of target compounds in the leaves *had the following* pattern: CBZ was accumulated in the mainly tip FLX mainly in the base and ATZ and TRI more uniformly in the all leaves. In corn leaves CBZ, FLX and ATZ were mainly accumulated in the base leaves and the transpiration normalized concentrations were lower than for *T.latifolia*. The rhizoma and sprouts of *T.latifolia* also contained measurable concentrations of the target compounds. No target compounds were detected in corn bud flowers. The results show the importance of examining the distribution of contaminants within the various plant tissues before conducting risk or biomonitoring assessments.

### RP045 MDD% as a guide to the size effect that can be estimated from regression

*J.W. Green, DuPont / Data Science and Informatics*

The concept of minimum detectible percent difference, MDD%, was explored for its relevance to the size effect that could be expected to estimate from regression. MDD% was developed for hypothesis testing and is routinely used in meso/microcosm studies, where few treatment groups are typically available, making regression analysis suboptimal at best. It is relatively straightforward to extend the MDD% concept to a simple linear regression model in studies with an ample number of treatment groups. In Staveley *et al.* (2018), it was shown that with suitable modification it can be extended to nonlinear models. The results of this study are used to explore the utility and limitations of MDD% in predicting the size effect that can be estimated reliably in a NTTP study. At the design stage, there is often a historical control database that indicates the typical variability on a per-species basis for each response of interest. To the extend MDD% is a reliable guide to what can be estimated, this information can serve at least two purposes. First, it informs the risk assessor what can be obtained from such studies. This will help in distinguishing between a real lack of effect and poor experimental design or analysis. Second, it may help in the selection of plants species to include in a study. If the test chemical has similar modes of action on two plant species but notably different variability leading to different size effects that might be estimable, then the species with lower variability might be preferred if it is acceptable on regulatory grounds to choose either species. A large database of non-target terrestrial plant (NTTP) studies collected by a team sponsored by Crop Life America was used to determine the extent to which the modified MDD% provided a reliable guide to the size effect that can be estimated reliably from a typical non-linear regression model fit to the data. ### RP046 Phytoplankton and cyanobacteria growth inhibition by glyphosate, imazamox and fluridone herbicides

*C. Lam, University of California, Davis; M. Vasi Stillway, University of California, Davis / VMAPC; P. Lehman, California Department of Fish and Wildlife; T. Kurobe, University of California, Davis; B.G. Hammock, UC Davis; S.A. Lesmeister, State of California, Department of Water Resources / Division of Environmental Services; S. Teh, University of California, Davis / UC Davis School of Veterinary Medicine*

Phytoplankton and cyanobacteria are key primary producers that form the base of the aquatic food web. In the Sacramento-San Joaquin Delta, primary productivity is low, limiting food availability for higher trophic levels. Blooms of toxin-producing cyanobacteria also occur in the summer and fall. Additionally, herbicides are employed yearly in the Delta to control invasive aquatic plants that block waterways and degrade habitat quality. Whether or not beneficial or harmful algae growth will also be inhibited by these herbicides is of interest due to the potential impact through trophic cascade to fishery production. For this study, we used 96-well plate growth tests to determine if algae growth is inhibited by the herbicides: glyphosate, imazamox and fluridone, which are currently used to control invasive aquatic plants in the Sacramento-San Joaquin Delta. For the growth inhibition tests, we used three species found in and/or isolated from the Delta: *Thalassiosira pseudonana* (diatom), *Microcystis aeruginosa* (cyanobacteria) and *Chlamydomonas sp.* (green algae). Growth was tracked daily by measuring optical density in the 96-well plates over five days. The extent of algae growth inhibition varied depending on the test species and the herbicide tested. We found that glyphosate and imazamox inhibited growth of all species at concentrations higher than what would be found in the environment, inhibiting growth between 7,000 ppb to 70,000 ppb, and between 20,000 ppb to 200,000 ppb respectively. However, fluridone inhibited growth of all algal species in concentrations at a lower environmentally relevant range of 10 to 300 ppb. *M. aeruginosa* and *T. pseudonana* were more sensitive than *Chlamydomonas* to all of the herbicides. Based on the varying sensitivities among algal species and herbicides, additional growth inhibition tests with a variety of native algae species can help managers identify contaminants and contaminant levels that will negatively impact beneficial or harmful species present in the Delta. Of the three herbicides tested, fluridone was the only chemical that inhibited algal growth at concentrations that could potentially be applied in the environment. Thus, fluridone treatments may decrease pelagic primary productivity in the Delta, although further experiments with field water are needed.

### RP047 The effect of buffering systems on pH-drift and Myriophyllum spicatum growth in OECD TG 239 tests

*G.P. Arts, Wageningen University and Research / Wageningen Environmental Research (Alterra); G. Rey, Wageningen University and Research / Wageningen Environmental Research, Environmental Risk Assessment*

The aim of this research was to improve the already existing OECD TG 239 *Myriophyllum spicatum* water-sediment toxicity test guideline by exploring methods to avoid or minimize pH-drifts. These pH-drifts normally occur when macrophytes are grown submerged in toxicity tests. On the one hand, pH and inorganic carbon resources are strongly interdependent and influence the growth of macrophytes. On the other hand, tested herbicides may be hydrolized because of increasing pH. In the experiment, pH drift and growth of *M. spicatum* were compared among control treatments, $CO_2$-bubbled systems, air-bubbled systems, and two treatments containing two different chemical buffers, i.e. MOPS (3-(N-morpholino) ethanesulfonic acid), and MES (2-(4-morpholino) ethanesulfonic acid). The test was performed twice. The first experiment showed a number of aberrations and low growth of the *Myriophyllum* shoots. In order to improve the set-up of the first experiment, a second experiment was performed with spring shoots and slight modifications. The $CO_2$-bubbling system resulted in a pH of around 6.0. Contrary to the first experiment, the air-bubbling system did not have an effect on pH. The MOPS and MES buffers managed to keep the pH around constant values of 7.5 and 6.9, respectively. However, the growth in these systems tended to be lower than in the control and the bubbled treatments. The growth in controls showed a RGR of dry weight of 0.04 ± 0.03 $g.g^{-1}.d^{-1}$ for the total shoots while this value was 0.081 $g.g^{-1}.d^{-1}$ for the $CO_2$-bubbling treatments and 0.066 $g.g^{-1}.d^{-1}$ for the air-bubbling systems. These results are comparable to those found in in literature. The increased growth in the bubbling systems tended to show that an input of $CO_2$ in the medium *via* a $CO_2$-tank or the ambient air allowed $CO_2$ assimilation which is a lower cost for submerged macrophytes compared to the use of $HCO_3^-$.The air-bubbling did not manage to maintain the pH at a constant range. It is recommended not to use chemical buffers because of a deleterious effect on *M. spicatum* growth. Further experiments are needed. For example, using a mixture of air and $CO_2$ could be a way forward to achieve a constant but higher pH. At the end, maintaining a pH constant over the duration of the experiment could ensure a proper growth of the macrophyte and avoid a fast degradation of the herbicide, leading to an unbiased exposure of the macrophytes to the herbicide.

**RP048 Acetaminophen Detoxification in Plants via Induction of Glutathione S-transferases**

*C. Sun, University of California, Riverside / Department of Environmental Science; S. Dudley, UC Riverside / Environmental Toxicology; J. Gan, University of California, Riverside / Environmental Science*

Many pharmaceutical and personal care products (PPCPs) enter agroecosystems during reuse of treated wastewater and biosolids. Research on the impact of pharmaceuticals in the environment has mainly focused on determining persistence, transport and concentrations in the soil; little work has been conducted to elucidate the mechanisms of pharmaceutical uptake, accumulation and detoxification by plants. Here, acetaminophen, one of the most-used pharmaceuticals, was used to explore roles of glutathione (GSH) conjugation in its biotransformation in crop plants. Acetaminophen was taken up by plants, and conjugated quickly with GSH. After exposure to 5 mg $L^{-1}$ acetaminophen for 144 h, GSH-acetaminophen conjugates were 15.2±1.3 nmol $g^{-1}$ and 1.2±0.1 nmol $g^{-1}$ in cucumber roots and leaves, respectively. Glutathione-acetaminophen was also observed in common bean, alfalfa, tomato, and wheat. Inhibition of cytochrome P450 decreased GSH conjugation. Moreover, the GSH conjugate was found to further convert to cysteine and N-acetylcysteine conjugates. Glutathione S-transferase activity was significantly elevated after exposure to acetaminophen, while levels of GSH decreased by 55.4% in roots after 48 h, followed by a gradual recovery thereafter. Enzymes involved in GSH synthesis, regeneration and transport were consistently induced to maintain the GSH homeostasis. Therefore, GST-mediated conjugation likely played a crucial role in minimizing phytotoxicity of acetaminophen and other PPCPs in plants.

## Environmental Assessments for Human and Veterinary Pharmaceuticals – Evolving Regulations

**RP049 Effect of Differing Regulatory Guidance on Acceptable Levels of Active Pharmaceutical Ingredients in Industrial Wastewater Discharges**

*N.D. Forsberg, Arcadis U.S., Inc. / Environmental and Molecular Toxicology; E.L. Osborn, Arcadis U.S., Inc.; B.H. Magee, ARCADIS; P.D. Anderson, Arcadis U.S., Inc.; N. Parke, Eli Lilly and Company / Global HSE – Environmental Affairs*

Wastewater discharge permits may not specifically regulate chemicals that are unique to the pharmaceutical and animal healthcare industries, such as active pharmaceutical ingredients (APIs). However, it is recognized that uncontrolled release of these chemicals has the potential to adversely affect the environment in areas downstream of the discharge. This issue can be addressed by determining acceptable concentrations of APIs and applying them to the downstream location where an exposure could potentially occur. However, a globally harmonized approach for the derivation and application of such acceptable concentrations does not exist, which can lead to substantial differences in the conclusions of risk assessments. To explore this issue, acceptable concentrations to which populations of aquatic organisms, wildlife, and humans could be exposed were calculated for a variety of APIs spanning several pharmaceutical classes using two approaches: USEPA's Great Lakes Initiative (40 CFR 132) and the European Union's Water Frame Work Directive (2000/60/EC) methods for deriving water quality standards. Acceptable concentrations were calculated using risk-based methods for several receptor-exposure scenario combinations, including acute and chronic exposure for aquatic organisms, chronic exposure for wildlife, and chronic exposure for humans associated with drinking water and recreational exposure scenarios. A sensitivity analysis was performed to evaluate the influence of the input variables and uncertainty in the underlying datasets on the calculated acceptable concentrations. Additionally, the effect of using US and EU-based approaches for evaluating the dilution capacity of receiving waters on the calculation of acceptable daily water discharges was compared. Recommendations are provided to help reduce uncertainty in the derivation of acceptable concentrations and wastewater discharge rates for APIs.

**RP050 Uptake and physiological responses to a model calcium channel blocker in fathead minnow across a dissolved oxygen gradient**

*G. Saari, S. Haddad, Baylor University / Environmental Science; R. Mole, University of North Carolina, Wilmington / Mathematics; B.N. Hill, Baylor University / Department of Environmental Science; B. Steele, Baylor University / Biomedical Studies; L. Lovin, Baylor University; K. Chambliss, Baylor University / Department of Chemistry and Biochemistry; B.W. Brooks, Baylor University / Department of Environmental Science*

Urbanized watersheds routinely represent worst case scenarios for fish exposure to multiple stressors, including contaminants of emerging concern (e.g., pharmaceuticals) and depressed dissolved oxygen (DO). Field observations from our laboratory identified concentrations of diltiazem, a calcium channel blocker used to treat high blood pressure, in fish plasma exceeding human therapeutic levels within multiple urban estuaries of the Gulf of Mexico. Additionally, these estuaries are commonly listed on the Texas, USA 303(d) list for non-attainment of DO water quality criteria. Therefore, we examined physiological responses to diltiazem across typical DO water quality criteria (WQC) values and developmental stages in the fathead minnow. Our results indicate DO significantly increases larval diltiazem toxicity following acute (48 h) exposures. DO levels (3.0 mg DO/L) consistent with current WQC values significantly doubled the uptake of diltiazem in adult fish relative to normoxic conditions (8 mg DO/L). Increased internal diltiazem concentrations were associated with significant increases in fish ventilation rate at low DO levels. Concomitant physiological responses revealed DO significantly decreased bursting swim performance ($U_{burst}$) by 12-31 % across diltiazem treatments. Such physiological effects paired with internal diltiazem tissue concentrations inform comparative physiology, pharmacology, and toxicology approaches to identify adverse outcomes, and further demonstrate the utility of employing model pharmaceuticals for basic and applied research.

## California Oil Spills: Impacts on Habitat and Wildlife

**RP051 Toxicity of High Energy Water Accommodated Fractions of Refugio Oil to Sand Crabs, Blue Mussels, and Inland Silversides**

*S.L. Clark, Pacific EcoRisk; B.M. Duke, California Department of Fish and Wildlife / Office of Spill Prevention and Response*

On May 19, 2015, the Refugio Beach Oil Spill occurred along the Gaviota Coast of California. As part of the evaluation of the effects of the spill on wildlife, aquatic toxicity studies were performed with multiple test species. As sand crabs, *Emerita analoga,*reside throughout the beaches impacted by the spill, sand crabs from an unimpacted population from Sonoma Creek Beach were collected to evaluate oil exposure effects on resident organisms via a 6-day test for which survival and growth (weight, length, incremental growth) were measured. In addition, the blue mussel, *Mytilus galloprovincialis*, larval development test and *Menidia beryllina* survival and growth test were conducted following standard EPA test protocols. All three organisms were exposed to high-energy water accommodated fractions (HEWAFs) prepared daily using filtered seawater and Refugio source oil following protocols established by the National Oceanic and Atmospheric Administration; a blended control was similarly prepared. Daily HEWAF solutions and filtered seawater were used to prepare nominal dilution series of 0.5, 1, 5, 10, 50, 100, and 500 µg/L. Significant reductions were observed in the *M. galloprovincialis*embryo development,*E. analoga* survival and growth (i.e., biomass, length, and incremental growth), and *M. beryllina*survival and mean dry weight test endpoints. The general order of sensitivity of the test species to the Refugio WAFs was *E. analogo*> *M. beryllina*>> *M. galloprovincialis*.

**RP052 Western Snowy Plover Reproductive Effects Associated with the Refugio Beach Oil Spill**

*J. Nielsen, C. Sandoval, University of California / Coal Oil Point Reserve; R.M. Donohoe, S. Hampton, California Department of Fish and Wildlife / Office of Spill Prevention and Response; J. Marek, US Fish and Wildlife Service / Environmental Contaminants*

During the May 2015 Refugio Beach oil spill, federally threatened western snowy plovers (*Charadrius nivosus nivosus*) were feeding with their recently hatched chicks on southern California beaches. They primarily forage on invertebrates in the wrack and wave-washed swash zone and were directly threatened by both the oil and the actions of the clean-up crews. During the spill, the extent and location of oiling observed on western snowy plovers at Coal Oil Point Reserve, in Santa Barbara, were documented. In addition, annual monitoring of reproductive success was conducted (i.e., number of nests, number of eggs laid, number chicks fledged, etc.), contributing to data collected on this population since 2001. Although no direct mortality of western snowy plovers was observed during the spill, a spike in the number of infertile eggs was observed in the year following the spill. As part of the Natural Resource Damage Assessment, estimated oil ingestion rates were compared to exposures associated with reproductive harm in other avian oil toxicity studies. A plausible connection between oil ingestion via preening and feeding and the increase in egg infertility in Western Snowy Plovers at Coal Oil Point Reserve was demonstrated.

**RP053 Marine mammal strandings following the 2015 Refugio Beach Oil Spill in Santa Barbara County, CA**

*S. Chivers, S. Wilkin, NOAA Fisheries; L. Henkel, California Department of Fish and Wildlife; L. Sullivan, NOAA / ORR /ARD*

An estimated 190,000 liters of crude oil entered the surf zone near Refugio State Beach in Santa Barbara County from an on-shore oil pipeline spill on May 15, 2015. Once in the ocean, the oil fouled local beaches and nearshore waters. The wildlife response team responded to reports of live and dead oiled marine mammals following the spill and recovered 162 marine mammals from Santa Barbara and Ventura County shorelines. Among the mammals recovered, there were 63 live pinnipeds, and 99 dead pinnipeds and dolphins. Of the 63 live pinnipeds captured and transported to rehabilitation centers for care, 23 were released. The primary species recovered was the California sea lion. The assessment of injuries to marine mammals resulting from the oil spill included a review of all wildlife intake records for recovered mammals and a comparison of them to historic records for Santa Barbara and Ventura county beaches. A summary of marine mammal stranding response activities and of the methods used to assess injury to mammals from the oil spill will be presented.

## Chemical Prioritization Using 21st Century Science: Considerations for New Approach Methodologies

**RP054 Application of Mass Balance Models to Understand the Behaviour of Organic Chemicals in In Vitro Toxicity Tests**

*J.M. Armitage, AES Armitage Environmental Sciences, Inc. / Physical and Environmental Sciences; J.A. Arnot, ARC Arnot Research & Consulting / Department of Physical & Environmental Science/Department of Pharmacology and Toxicology*

Toxicity testing in the 21st century is expected to rely increasingly on in vitro assays, which now cover a wide range of endpoints including cytotoxicity, receptor binding, protein interactions and DNA binding. In most cases, dose-response relationships from in vitro toxicity tests are reported using nominal concentrations in the test medium despite the known challenges such data introduce for comparing results across different test conditions and between different chemicals. With respect to existing data reported on a nominal basis (e.g., ToxCAST™), one option to further probe reported results is to apply mass balance models to simulate the distribution of the chemical in the test system. Indeed, equilibrium partitioning (EQP) and toxicokinetic (TK) models have already been published in the literature for this purpose. The main objective of this study was to develop and apply EQP and TK models under both generic (hypothetical) and actual in vitro toxicity test conditions to better understand the potential behaviour of organic chemicals in these systems. For relatively persistent chemicals (or in cells/tissue with limited metabolic competency), the simulated mass distribution using the TK model is similar to the equilibrium partitioning model output for test durations greater than 12 h. Based on these results, we then applied the EQP model to a specific ToxCast assay (ACEA_T47D_80hr_negative assay; cytotoxicity) to illustrate the value of this modelling approach. For approximately 300 neutral organic chemicals with “Hits” (i.e., reported AC50s) included in these simulations, approximately 2/3rds had predicted membrane concentrations (at the AC50) in the range consistent with baseline toxicity (membrane dysfunction/narcosis). Chemicals with predicted membrane concentrations well below the baseline toxicity range may act via a specific mode of action and could therefore be prioritized for further investigation. The EQP model also provided insights into the approximately 900 chemicals with “Misses” (no response) in the same assay

**RP055 Comparing Mode of Action (MOA) classification using body residues, membrane concentrations and chemical activity for chemical prioritization**

*J.M. Armitage, AES Armitage Environmental Sciences, Inc / Physical and Environmental Sciences; J.A. Arnot, ARC Arnot Research & Consulting / Department of Physical & Environmental Science / Department of Pharmacology and Toxicology; M.A. Bonnell, Environment and Climate Change Canada / Ecological Assessment Division*

In 2016, Environment and Climate Change Canada (ECCC) released the first version of an IATA-like Ecological Risk Classification system (ERC1) for prioritizing the organic substances on the Canadian Domestic Substances List (DSL) remaining to be assessed before 2020. One of the key considerations for assessing toxicity in ERC1 is a Mode of Action (MOA) classification which aims to distinguish between baseline toxicants (“narcotics”) and specifically-acting toxicants in a given test organism/receptor. As part of the MOA classification for aquatic organisms (fish), ERC1 used an estimate of the Critical Body Residue (CBR) corresponding to an empirical or QSAR-based lethal concentration (LC50). Two alternative/complementary metrics for MOA classification that have been advanced recently are i) Critical Membrane Concentration (CMC) and ii) (lethal) chemical activity (La50). At the screening level, the CBR, CMC and La50 approaches rely on different physical-chemical properties to “translate” the LC50, namely octanol-water partitioning ($K_{OW}$), membrane-water partitioning ($K_{MW}$) and water solubility respectively. The main objective of this study was to generate CBRs, CMCs and La50s for a set of 929 neutral organic chemicals with empirical LC50 data and compare the MOA classifications across the three metrics and to the MOA classification based on another approach applied in ERC1 (structural alerts). Complete agreement in the screening level MOA classification using CBR, CMC and La50 was observed for 719 of 929 chemicals (599 baseline toxicants, 120 specifically-acting). Complete agreement in the screening level MOA classification using CBR, CMC, La50 and structural alerts was observed for 585 of 929 chemicals (522 baseline toxicants, 63 specifically-acting). Explanations for the apparent discrepancies include uncertainties in property measurements/estimates, problematic toxicity data (e.g., LC50s greater than water solubility) and the domains of applicability for all approaches (including MOAs based on structural alerts). The findings of this exercise will be used to inform version 2.0 of the ERC, which is being developed as one approach to determine chemical priorities for post 2020 chemicals management in Canada.

## Soil Contaminants: Fate, Bioavailability, Environmental Toxicology in Ecological and Human Health Risk Assessment

### RP056 Can soil invertebrate traits help us understand interspecies differences in responses to petroleum hydrocarbon contaminated soils?

*A. Gainer, University of Saskatchewan / Toxicology Centre / Soil Science, Toxicology; S. Siciliano, University of Saskatchewan / Department of Soil Science*

Soil invertebrates display a range in interspecies sensitivities to petroleum hydrocarbon contaminated soils in terms of mortality, reproduction and avoidance. For instance, in our studies we found, mortality of two phylogenetically similar species, *Eisenia fetida* and *Enchytraeus crypticus*, exposed to petroleum hydrocarbon contaminated soils ranged several orders of magnitude, from 2,860 to over 186,000 mg/kg total petroleum hydrocarbons. With many contaminants, the avoidance response is typically as sensitive as reproduction, however, we found the predatory mite, *Hypoaspis aculeifer,* avoidance an order of magnitude greater than its reproduction. Trait based approached have been a successful tool in monitoring community changes following exposure to low concentrations of pesticides in German rivers. We qualitatively discuss how traits explain the interspecies variations of six soil invertebrates responses to petroleum hydrocarbon contaminated soils.

### RP057 Environmental risk analysis for crude oil soil pollution

*I. Onutu, Oil and Gas University of Ploiesti / Department of Petroleum Processing Engineering; A.S. Paul, University of Lagos / Department of Chemistry Faculty of Science*

Environmental risk assessment (ERA) is predominantly a scientific activity and involves a critical review of available data for the purpose of identifying and possibly quantifying the risks associated with a potential threat. Risk management (RM) is performed to consider the need to impose measures to control or manage the risk. The working methodology presented in this paper was done based on several research studies for the environmental risk assessment for soil pollution with hidrocarbures from accidental crude oil spills. The qualitative and quantitative assessment of the environmental risk for industrial sites for drilling, gas oil separation it is complex and require several data. For these reasons an environmental risk calculation methodology for soil is presented which is structured in modules and steps. Environment risk assessment of pollution with hydrocarbons from crude oil comprises five interrelated modules: hazard identification, hazard assessment, risk estimation by the award of "grades" for the frequency and severity of consequences environmental risk assessment based on risk criteria (ALARP) and environmental risk management. The modules required data: technical data for the equipment in the upstream industrial activities, extraction and gas-oil separation, physico-chemical analysis for the soil contaminants, soil properties that may influence the severity and consequences of the default risk, charts, mathematical equations and matrix assessment of environmental risk intensity. In the methodology are established the steps needed to calculate the alert threshold and intervention and additional studies needed (geotechnical study, pedological and chemical study).

### RP058 Polycyclic Aromatic Hydrocarbon Accumulation in Soil throughout Oklahoma City, Oklahoma

*S. Hileman, J.B. Belden, Oklahoma State University / Integrative Biology*

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous in the environment and have been found to be of concern with regards to human health. PAH contamination may correspond with atmospheric deposition, and in urban environments soils may contain elevated levels due to proximity to combustion sources. Sampling in the Oklahoma City Metropolitan Area has indicated that PAH accumulation (and especially carcinogenic PAHs or cPAH concentration) has been significant, and in many cases cPAH load has been measured above the USEPA's residential soil screening level of 110ppb. The Oklahoma City Metropolitan Area varies in industrial landscape causing school proximity to major areas of traffic to differ. Included in this initial sampling were soils from school areas which showed the overall highest levels of cPAHs and benzo[a]pyrene (B aP). Because schools in this metropolitan range tend to have a high degree of concern, there is the potential for oral exposure to PAHs in sensitive age groups by way of hand-to-mouth actions involving soil. Additional preliminary data from playground soil at elementary schools throughout the Oklahoma City Area have shown elevated but varied cPAH levels. These sites should be further investigated to determine potential sources of contamination.

### RP059 Potential risk of biomass-derived biochars as soil amendments

*L. Luo, Research Center for Eco-Environmental Sciences / The Chinese Academy of Sciences / State Key Laboratory of Environmental Chemistry and Ecotoxicology; Z. Chen, Research Center for Eco-Environmental Sciences / The Chinese Academy of Sciences; J. Lv, Research Center for Eco-Environmental Sciences / The Chinese Academy of Sciences / State Key Laboratory of Environmental Chemistry and Ecotoxicology; S. Zhang, Research Center for Eco-Environmental Sciences / The Chinese Academy of Sciences*

Biochar is gaining increasing attention agricultural and environmental fields due to its high surface reactivity for contaminant immobilization and strong ability for carbon sequestration. Various agricultural wastes including swine manures and sewage sludge were used as biomass feedstocks to produce biochars, which was suggested as a promising method to utilize the wastes. Unfortunately, the potential risks from biochars have not been well-documented.This work reported potential risk of maize straw- and swine manure derived biochars pyrolyzed at 300 and 500°C. During the pyrolysis processes, total heavy metals in the biochars were enriched greatly accompanying with considerable emission of the heavy metals into atmosphere and the trends became increasingly obvious at high pyrolysis temperature. Meanwhile, the biochars showed significant changes in the speciation of the heavy metals compared to raw feedstocks. The changes in the chemical speciation and matrix properties led to reduced availability of the heavy metals in the pyrolyzed products. The water- and acid-washing treatments could significantly increase the releasing risks of heavy metals from biochars into the environment. The biochars usually contained environmental persistent free radicals, which emerged strongly as a function of the aromatization of biomass feedstocks and could exert negative effects on the growth of plants and microorganisms. Electron paramagnetic resonance analysis confirmed that the environmental persistent free radicals were free from the influence of water-, acid-, or organic-washing of the biochars and could remain stable even after aged in soils for 30 days. Dissolved biochars, the water-soluble fraction of biochar, showed distinct properties including lower molecular weight distribution while higher aromaticity compared to soil dissolved organic carbon. The dissolved biochars could act as both sorbent and carrier for contaminants and thus increase greatly the risk of mobilization and transportation of the associated contaminants in the environment. This study explore the transformation and occuring mechanisms of the materials with potential risk in biochars. The results of this study provide important perspectives on the possible risks and the safe usage of biochars as soil amendments.

**RP060 Recommendations on the Use of Existing Toxicological Data/ Information for Evaluating Noncancer Hazards of Uranium at Mining Sites**

*D. Llee, Arcadis In; B.H. Magee, ARCADIS; D. Pfeiffer, Arcadis U.S., Inc.*

The current chronic oral reference dose (RfD) for uranium (0.003 mg/kg/day) listed in USEPA's Integrated Risk Information System (IRIS) is based on a lowest observed adverse effect level from Maynard and Hodges (1949). USEPA (2000) used a study by Gilman et al. (1989) for derivation of a Maximum Contaminant Level (MCL) for uranium. In 2002, the USEPA IRIS program reviewed the RfD based on the Maynard and Hodges study and other available studies, including the Gilman study, and did not revise the IRIS RfD. ATSDR (2013) has recently developed an oral intermediate minimum risk level (MRL) of 0.0002 mg/kg/day for uranium (soluble salts) based on the Gilman study. Lastly, in 2016 the Superfund Technical Support Center recommended that the published IRIS RfD be rejected and the ATSDR MRL be used for risk assessment purposes. The Gilman study has serious shortcomings primarily because identified effects do not reflect a dose-response relationship which is a requirement for determining that an observed effect was due to treatment versus chance. In *A Review of the Reference Dose and Reference Concentration Processes* (USEPA 2002), USEPA states that a study used for RfD derivation should establish a dose-response relationship, and the shape of the dose-response curve should be consistent with the known toxicokinetics of the compound. Furthermore, in addition to being statistically significant, the effects used for RfD derivation also need to be biologically significant. The Gilman study does not meet any of these criteria. The uranium oral RfD is currently in Step 1 of the IRIS program review process, so a revised RfD from USEPA is not expected for some time. In the interim, risk assessors have to decide whether to use the existing IRIS RfD, the ATSDR MRL (used to develop RSLs), or a *de novo* RfD that they derive and support with adequate documentation. This presentation will perform a critical review of current toxicological reference values, discuss specific deficiencies in the Gilman study, demonstrate the inability to derive a benchmark dose using the USEPA (2014) Benchmark Dose Software program, and make recommendations as to how to assess the noncancer risks posed by uranium.

**RP061 Risk Assessment of Metals in Bulk and Fine Fraction Mine Waste Soil**

*J.A. Kountzman, Black & Veatch / Special Projects*

The U.S. Environmental Protection Agency currently recommends sieving soil with a #100 sieve to obtain a fine fraction (< 150 µm particle size) for assessment of human health risk due to incidental ingestion at Lead Sites. This recommendation is based on a review of particle size distribution of metals in shooting ranges, incinerators, mine tailings and background soil samples from mining sites and urban soils that demonstrated consistent enrichment in particle size fractions smaller than 150 µm (EPA, 2016). Furthermore, EPA recommends that the fine fraction be used for determining site-specific bioavailability and site-specific background. As part of an investigation at a historic mining area, 110 co-located bulk and fine fraction mine waste soil samples were collected and analyzed for arsenic, barium, cadmium, chromium, cobalt, copper, lead, silver, vanadium, and zinc. The data from the coarse and fine soil fractions were used to calculate the relative percent difference (RPD) between the two sets of data. In addition, regression analysis of the paired concentrations of each metal was performed to determine the nature of the relationship for the mine waste soils. A summary of the analytical results, the RPDs between the bulk and fine fractions, and regression analysis are presented for each metal. The degree of enrichment in the fine fraction was determined to be metal specific. The regression equations and trendlines demonstrate that although some sample pairs show evidence of enrichment for some metals, the data predominantly indicates that the concentrations in the fine fraction tend to be lower than the concentration in the coarse fraction. Since the fine fraction is more representative of the concentration available to both human and ecological receptors, use of coarse sample results may overestimate exposure and risk for the site. Recommendations for incorporating metal enrichment data in risk assessments of mine waste sites are presented and discussed.

**RP062 Development of an area-specific bioavailability factor for assessing human exposure-risk to arsenic in soils in southeastern Idaho**

*D. Pfeiffer, Arcadis U.S., Inc.; D. Llee, Arcadis In; B.H. Magee, ARCADIS; M. Hay, ARCADIS Inc.*

Cancer risks associated with exposures to arsenic via soil ingestion often drive human health risk assessments and understanding the range of arsenic bioavailability in soil at a site is important to avoid the overestimation of site-related human health impacts and unwarranted remediation costs. The United States Environmental Protection Agency currently recommends a default relative bioavailability factor of 60 percent for ingestion of arsenic in soils based upon the highest estimated RBA value from 11 hazardous waste sites using the juvenile swine method and summarize the relationship between the form of the arsenic and high, medium and low bioavailability. In this poster, the geochemistry at a site in the western US is presented to show that arsenic in the soil environment is most likely present as arsenate and/or arsenite strongly associated with iron oxyhydroxides rather than as a pure arsenic phase such as arsenic trioxide or arsenic sulfide. The high concentrations of iron compared to arsenic at the site also demonstrates an abundance of iron for adsorption and/or coprecipitation of arsenic, which is consistent with the association of arsenic with iron oxyhydroxides. This geochemistry is then tied to available USEPA studies to derive a site-specific relative bioavailability factor of 45 percent to reduce uncertainties associated with arsenic risks from soil ingestion.

**RP063 As, Cd and Pb Bioavailability in Contaminated Soils: Application to Soil Remediation**

*L. Ma, SW Forestry University / Research Center for Soil Contamination and Environment Remediation; H. Li, J. Li, S. Li, Nanjing University / School of the Environment; A. Juhasz, University of South Australia / Centre for Environm Risk Assessment Remediation*

When considering metal exposure to humans via incidental ingestion of soil, daily intake will not only be influenced by their concentrations in soils but also by their bioavailability. While different animal models and feeding schemes have been used to assess metal-RBA, comparative studies detailing the influences of these parameters on metal-RBA measurement are lacking. In addtion, time, cost and ethical considerations limit use of in vivo assays. Therefore, in vitro assays have been developed to determine the amount of metal extracted from soil matrix in simulated human gastric and intestinal fluid, i.e, bioaccessibility. However, to determine if these assays provide a good prediction of metal bioavailability in soil, it is important to establish the relationship between in vitro bioaccessibility and in vivo RBA. However, established IVIVCs are often soil specific, varying with the soils used. Furthermore, to date, no study tested the feasibility of in vitro assays to predict metal-RBA in contaminated soils from China. The objectives of this study were 1) to compare metal-RBA in contaminated soils determined by use of different animal models to determine how in vivo operational parameters impact RBA determination; 2) establish IVIVC for metal in contaminated soils from China by correlating bioaccessibility determined using in vitro assays to RBA measured using in vitro mouse bioassays. The importance of including metal-RBA for refining metal exposure assessment and modifying soil cleanup standards for contaminated soils will be discussed

**RP064 Risk Assessments at Closed Small Arms Shooting Ranges Need to Consider Lead in Soil and in Lead Bullet and Shot Sources**

*J. Spearow, California EPA Dept of Toxic Substances Control; C. Tsao, California Department of Fish and Wildlife / Office of Spill Prevention and Response*

Current procedures for evaluating lead at shooting ranges may miss lead in bullets and shot. Lead bullets/fragments/shot account for most of the lead remaining at shooting ranges which continue to weather to more soluble lead compounds in a site-specific manner (Rooney and McLaren 2000; Rooney et al., 2007). Each 150 grain, .30 caliber bullet initially contains ~8000 mg lead. The complete release and mixing of lead from one .30 caliber bullet would bring 100 kg of soil to the 80 mg/kg lead screening level for residential use in California. However, there is only about a 1 in 100,000 chance the bullet would be analyzed using grab sampling because EPA Method 3050B/6010B only digests 1 gram soil. This is not sufficient to assess risk of future use, since over 99.9% of the samples would miss the bullet and underestimate total lead and future lead exposures. We developed a screening-level survey approach that allows a metal detector to rapidly screen the top 6 inches of soil for density of lead bullets that would exceed 80 or 400 mg/kg total lead after complete bullet dissolution. Lead bullets were not visible at several shooting ranges that had been closed for 40 to 70 years, but were easily detected in the top 6 inches of soil with a suitable metal detector. Screening rifle and pistol ranges with a suitable detector easily identified many locations with a high density of lead bullets and over 10,000 mg/kg total lead that had been missed by gridded sampling for lead using X-ray fluorescence (XRF). This approach enhances initial screening of shooting ranges to help determine the lateral extent of lead bullets/shot. Combining this approach with measuring lead in fine soil, enables a more accurate estimation of total lead and future lead exposures. Thus, shooting ranges should also be screened for density of lead bullets/shot with a suitable metal detector. For detecting No. 9 lead shot, a different detector was suitable at up to 2 inches and could also aid in screening skeet ranges for regions of lead shot deposition and potential bird ingestion exposure. To account for total lead, we recommend collecting large samples where spent ammunition is most concentrated, sieving the entire sample to recover and quantitate lead bullets/shot gravimetrically. Lead should also be measured in fine sieved soil by XRF or EPA Method 3050B/6010B. Cleanup and risk management decisions regarding future use should be made on total lead in combined lead bullets/shot and fine soil.

**RP065 Recreational Exposure to Game Species Based on Habitat and COPC Soil Concentration**

*T. Biksey, C. Peterson, EHS Support LLC / Risk Assessment*

A preliminary conceptual exposure model (CEM) for a northwestern aluminum recycle facility shows the potential exposure to constituents of potential concern (COPCs) by recreational users (i.e., hunters). The site environment includes the facility operational area, landfills, and undeveloped areas. Extensive environmental sampling indicates variable distribution and concentration of COPCs across the site with higher concentrations associated with operational areas and landfills. Site human health exposure areas based on potential current and future land use includes commercial/industrial, residential, and recreational uses within the operational areas, landfills, and undeveloped areas. The terrestrial habitats associated with human health exposure areas that are uncovered consists of mixed conifer forest, riparian forest, deciduous shrubland, and open grasslands, and transitional habitats characterized by intermittent or seasonal surface water inundation that flow through the terrestrial habitats; these support multiple terrestrial receptor groups including game species. To assess the potential risks to the recreational hunter from the ingestion of game species foraging on the site, an exposure point concentration (EPC) of the COPCs is required to develop the dietary intake exposure model for the hunter using bioaccumulation factors. For game species with a wide-ranging foraging area (i.e., white-tailed deer), the exposure to COPCs will vary by the magnitude of the COPC-specific EPC in the soil of a specific human health exposure area, the habitat quality association with that exposure area, and the home range of the species. The habitat quality for each specific human health exposure area is a measure of species-specific habitat and life history characteristics. A GIS based web map provides the spatial scale for the habitat quality and COPC-specific EPC to estimate a site-wide weighted COPC-specific EPC for game ingestion exposure model. An example of the methodology using the white-tailed deer is presented. A sensitivity analysis provides a range of potential risks from variations in the area of future land use for recreational hunting.

**RP066 Iterative Evaluation of the Costs and Benefits of Determining Site-Specific Bioavailability: Case Study for Metal Grinding Dust**

*A. Verwiel, D. Proctor, M. Suh, ToxStrategies Inc*

Bioavailability is recognized as an important consideration in human health risk assessment because toxicity testing is conducted using forms of chemicals that are well absorbed, but chemicals in environmental matrices are frequently less available for absorption. Almost 30 years ago, Risk Assessment Guidance for Superfund suggested that bioavailability could be considered in human health risk assessment. But time, expense, effort and uncertainty surrounding regulatory acceptance, frequently outweighed the benefits of a more accurate assessment of potential health risks. With the advent of regulatory guidance (USEPA, 2007, 2017, ITRC, 2017) and the accumulation of scientific literature, bioavailability is a more accepted tool in risk assessment. Iterative assessment of the costs and benefits of quantitative bioavailability testing as data is gathered can facilitate the timely and effective integration of site-specific bioavailability into risk assessments. Based on recent experience with in vitro and in vivo bioaccessibility of nickel and cobalt from metal grinding, we have developed a road map for developing quantitative bioavailability applicable to other projects. This road map includes five steps: initial site characterization, in vitroassessment, further site characterization, pilot in vivo study, and comprehensive in vivo study. Practical and scientific considerations should be reviewed, such as regulatory acceptance and impact on potential remediation efforts, and solubility of metals in impacted media and the biological uptake of specific metals of interest. As the project progresses, the costs and benefits should be re-evalutated, such when the scope of remediation is further defined, changing the associated costs (up or down). Additionally, the results of in vitroand pilot in vivotesting may indicate that a full study would not sufficiently vary from the default of 100% or be too uncertain due to biological and kinetic factors. Incorporating input from clients, regulators stakeholders, and scientists through the course of the project is also important. For example, regulators who are unfamiliar with bioavailability testing may be unwilling to accept the results, eliminating most benefits of performing these tests. The road map outlined in this presentation provides a pragmatic approach for developing site-specific bioavailability for risk assessments.

**RP067 Pilot study on effects of U mining on cultural resources in the Grand Canyon watershed: Potential implications for Native American risk assessments**

*D. Cleveland, J. Hinck, USGS / Columbia Environmental Research Center*

The Grand Canyon watershed contains economically viable high-grade uranium (U) ore deposits in various stages of exploitation, yet the potential risks of U mining to Native American cultural resources are not well known. The staggered mining life stages and regional distribution of these deposits may result in prolonged exposure of biota, and subsequently to humans using the resources, to U mining-related constituents. Radiological concerns about U are often at the forefront of public concern, but U and other co-occurring elements may also pose toxicological risks. Previous work has indicated that aeolian transport of dust from the mine sites contributes to elemental-loading on vegetation beyond mine perimeters. We aim to develop a Native American risk assessment model for U mining, which will likely need to include additional considerations compared to a standard human health risk assessment. In this pilot study, unwashed sagebrush (*Artemisia tridentata*) collected from pre-production and post-mining locations, and from a nearby traditional cultural property, was burned to characterize chemical constituents in particulates under a simulated traditional use; thus evaluating inhalation risks. Particulate matter was vacuum-collected on a filter, and then analyzed for metals concentrations. Results from burned samples will be compared to particulates collected from unburned sagebrush, and to sagebrush collected up- and down-wind at and near the U mine sites. Results will also be used to determine whether further studies are needed to identify potential human inhalation risks associated with the cultural use of resources obtained near U mines.

**RP068 Health risk assessment of heavy metals from informal e-waste processing in Alaba International Market, Lagos, Nigeria**

*A. Adebayo, Federal University of Petroleum Resources Effurun / Environmental Management and Toxicology; O. Osibanjo, University of Ibadan / Department of Chemistry*

Informal electronic waste (e-waste) processing is a crude method of recycling, which is on the increase in Nigeria. The release of hazardous substances such as heavy metals (HMs) into the environment during informal e-waste processing has been a major concern. However, there is insufficient information on environmental contamination from e-waste recycling, associated human health risk in Alaba International Market, a major electronic market in Lagos, Nigeria. The aims of this study were to determine the levels of HMs in soil, resulting from the e-waste recycling; and also assess associated human health risk in Alaba international market. Samples of soils (334) were randomly collected seasonally for three years from four selected e-waste processing activity points namely; burning, dismantling, stockpiling and disposal. The samples were digested using standard methods and HMs analysed by inductive coupled plasma optical emission. Human health risk was done using hazard index (HI) for non carcinogenic elements and total cancer risk index ($R_{TOTAL}$) for carcinogenic elements. The concentrations of HMs (mg/kg) in soil samples from all studied areas showed that levels were several orders of magnitude higher than the background values. The following conclusions could be drawn from the carcinogenic and non-carcinogenic health risk assessment; the exposure pathway that results in the highest level of health risk was inhalation followed by dermal and lastly by ingestion. The hazard indices of Pb were above the threshold value of 1 for non-carcinogenic hazard risk indicating a possible risk of neurological and developmental disorder in children. The hazard indices for the four carcinogenic heavy metals Cd, Co, Cr and Ni were above the threshold range of $10^{-4}$ to $10^{-6}$ indicating a high risk of cancer in children and adults. The potential carcinogenic risk order with respect to e-waste processing activity is Burning> Dismantling> Disposal> Stockpiling. Generally, the levels of carcinogenic and non-carcinogenic risks were unacceptable being in excess of $1 \times 10^{-6}$ and 1 thresholds for $R_{TOTAL}$ and HI, respectively. Heavy metal contamination of Alaba international market environment resulting from informal e-waste processing was established. Proper management of e-waste and remediation of the market environment are recommended to minimize the human health risks.

**RP069 Assessment of the Environmental Pollution Effect of Lead Mining in Ebonyi State**

*A.I. Onwurah, University of Nigeria, Nsukka / Environmental Management; F.A. Atawal, University of Nigeria, Nsukka / Zoology and Environmental Biology*

The role environmental quality plays in human and animal health is unprecedented. In this work, we evaluated the health of the people, and plants in a community in Ebonyi State where mining activities had been on for over ten (10) years. Lead mining activities are the major sources of the contaminants The levels of contamination of bitter leaves (*Vernonia amygdalina*), ora leaves (*Pterocarpus mildbraedii*), scent leaves (*Ocimum gratissimum*), okra pods (*Abelmoschus esculentus*), curry leaves (*Murraya koenigii*) and garden eggs (*Solanum melongena*), soil and water , arising from the mining area in this community were evaluated. This becomes important as these plants as sources of food while water is used for different domestic purposes and even drinking. Toxicity of water samples were tested using the "ostracod (*Hetrocypris* incongruens) toxicity assay kit" and that of soil in earthworms. Results show that the concentrations the various vegetables, soil and water samples decreased as distances progressed from the mining site. There was no observed mortality of earthworms after 72hours of exposure to the various lead-soil samples. However, 10% mortality of earthworms (after 7 days) and 22.2% mortality (after 14 days) were observed in lead-soil samples collected 0.05km away from the mining site, while 10% mortality was observed (after 14 days) in lead-soil sample collected 2km away from the mining site. Percentage mortality of ostracod crustaceans exposed to lead-water samples decreased as distances progressed from the mining site, but remained constant after distance of 4km. Both Estimated Daily Intake (EDI) and Target Hazard Quotient (THQ) for lead in both adult and children for consumption of all the samples collected around the mining area decreased as distances progressed from the mining site. For some of the samples the EDI values were below the Tolerable Daily intake (TDI) for lead while for others, EDI values were above the TDI in both adult and children. Target Hazard Quotient (THQ) of lead in both adult and children for consumption of the various samples was greater (>) 1 for some of the samples and less (<) 1 for other samples. It is predicted that residents around lead mining sites are prone to health hazard and should therefore limit exposure. Also this result can help the local authority in planning for better management of these areas to ameliorate the negative health effect of the mining site on the community and map out environment recovery steps.

**RP070 Low concentrations of carbonaceous nanomaterials in soil affect soybean growth and dinitrogen fixation**

*Y. Wang, University of California, Santa Barbara; C. Chang, Z. Ji, University of California, Los Angeles; D.C. Bouchard, USEPA / EMMD; R.M. Nisbet, J.P. Schimel, University of California, Santa Barbara; J.L. Gardea-Torresdey, The University of Texas at El Paso / Department of Chemistry / Department of Environmental Science and Engineering; P.A. Holden, University of California*

With the increasing exposure of agricultural soils to carbonaceous nanomaterials (CNMs), terrestrial crop plants may be at risk. Published research, much of which has been conducted under hydroponic conditions over short-term periods, has shown a mix of positive and negative effects of CNMs on plants. However, long-term CNM effects on plants, including effects on plant-microbe interactions, are still relatively poorly understood. In this work, we determined the relative effects of two engineered CNMs (multi-walled carbon nanotubes and graphene) versus industrial carbon black on the growth and dinitrogen ($N_2$) fixation of soybean grown to bean production stage in soil. Each type of CNMs had three concentrations (0.1, 100, and 1000 mg $kg^{-1}$ dry soil). Plants grown with the lowest concentration of carbon nanotubes were shorter and had a lower leaf area at harvest. However, all three CNMs—at all concentrations—accelerated plant flowering. Root nodulation and $N_2$ fixation potential appeared negatively affected by CNMs, with stronger inhibitory effects more frequently occurring with the lower concentration CNM treatments. This inverse dose-response relationships were explained by the greater CNM agglomeration at higher concentrations which likely decreased CNM dispersal and bioavailability in soil, and thereby decreased the effects on plants. Overall, our work shows that low concentrations of CNMs in soil could have relatively high impacts on soybean growth and $N_2$ fixation. The discovery that CNMs can show inverse dose-response relationships means that CNMs may cause damage to ecosystems at concentrations lower than we might have otherwise assumed. Additionally, this highlights the importance of the processes that control CNM agglomeration and the stability of the agglomerates in regulating the overall effects of CNMs on terrestrial ecosystems.

**RP071 Ecological risk assessment for the PAHs-contaminated soils using a luminously modified freshwater bacterium**

*H. Keum, Korea University / College of Life Sciences and Biotechnology*

Polycyclic aromatic hydrocarbons (PAHs) are organic compounds that are manufactured in the industry. Another major source of PAHs is the incomplete combustion of organic material such as coal, oil, and wood. PAHs are commonly exist in air, soil, and water. Thus, they are considered ubiquitous in the environment (Zhang and Tao, 2009). PAHs in the soil will be bound to soil particles so that they can move (Masih and Taneja, 2006). PAHs are highly lipid-soluble and also very soluble in organic solvent. The water solubility of PAHs decreases for each additional ring (Wilson and Jones, 1993; Haritash and Kaushik, 2009). The toxicity of PAHs is due to the formation of reactive metabolites. It has been proven that PAHs have carcinogenic and mutagenic effects (IARC 2010). Especialy, benzo(a)pyrene (BaP) is the first chemical carcinogen to be discovered and known to cause cancer in animals (USEPA 2008). Soil samples were taken from the clean site of a mountain (Hongcheon, South Korea) and air-dried and sieved through a 2 mm sieve. Optimum doses of Hb and $H_2O_2$ for degradation and detoxification of pyrene in soil samples were obtained from previous studies (Keum et al., 2017a; Keum et al., 2017b). The Hb concentration of 0.010 g (g soil)$^{-1}$ and $H_2O_2$ concentration of 0.03 g (g soil)$^{-1}$ were employed. The toxicity of uncontaminated control soil were compared with those of pyrene- or BaP-contaminated soils. Soils were contaminated with pyrene or BaP at a concentration of 10 mg kg$^{-1}$ and was treated with phosphate buffer (pH 7.0) for 24 h. Then, the soil was extracted and analyzed to measure EC50 concentration. After remediation of organopollutants in soil, it is necessary to estimate the toxicity extents and the effect on microbial community. Many previous studies have reported the remediation of organopollutants with the use of Hb and $H_2O_2$. However, until now, almost no attention has been given to the estimation of correlation between degradation progress and biotoxicity extent during the remediation with the use of Hb and $H_2O_2$. Here I have reported the comparison of toxicity with two bioluminescent bacteria *V. fischeri* and *J. lividum* YH9-RC during the remediation of pyrene and BaP. The bacterium *V. fischeri* has been employed for a long time to estimate a toxicity of organic compounds. However, in the present study, I have shown that the other bacterium *J. lividum* YH9-RC might be a better choice to estimate the change in toxicity of pyrene and BaP in soil.

**RP072 Back Conversion from Methyl Triclosan to Triclosan in Soil-Earthworm System**

*X. Du, University of California, Riverside; Q. Fu, Eawag, Swiss Federal Institute of Aquatic Science and Technology / Department of Environmental Chemistry; J. Gan, University of California, Riverside / Environmental Science*

Numerous pharmaceuticals and personal care products (PPCPs) pass through wastewater treatment plants (WWTPs), where biological and chemical treatments often result in the formation of a wide range of transformation products via reactions such as conjugation and alkylation. When wastewater irrigation or biosolid application occurs, such transformation products may be released into soil and taken up by soil organisms such as earthworm. In the present study, the high-volume antimicrobial triclosan was used as a model compound to investigate the back conversion from metabolites to parents. After 14-day exposure to environmentally relevant concentrations of methyl triclosan (a primary triclosan metabolite), the parent compound triclosan was detected in the soil. In the methyl triclosan exposed soil-earthworm system, triclosan was found in both soil and earthworm samples with triclosan level of 0.012 and 2.0 µg/g dw, respectively. The bioaccumulation factors (BAF) of methyl triclosan and triclosan were 21.5 and 172 respectively. Consistent occurrence of triclosan in soil confirmed the transformation of methyl triclosan to triclosan in soil. Relatively high BAF values of triclosan showed that biotransformation of methyl triclosan very likely occurred in earthworm after uptake. The back and forth conversion of contaminants such as triclosan extends the environmental persistence and exposure of parent compounds. The occurrence and fate of transformation products should be taken into consideration when assessing environmental risks of emerging contaminants.

**RP073 Those crazy kids: Is juvenile soil invertebrate avoidance to contaminated soil more sensitive than adults?**

*A. Gainer, University of Saskatchewan / Toxicology Centre / Soil Science, Toxicology; R. Akre, University of Guelph; S. Siciliano, University of Saskatchewan / Department of Soil Science*

Avoidance tests are simple toxicity tests with field and ecological relevant findings. Currently, the majority of soil invertebrate avoidance testing is conducted on adults, with no literature on juvenile avoidance responses. Existing toxicity literature in aquatic and soil environments agree, juveniles are more sensitive to toxicants than adults. In this study, our objective was to determine if juvenile avoidance response was more or less sensitive than the adults. We tested the dual avoidance response of adult and juveniles of three standardized soil invertebrates (*Folsomia candida, Enchytreaus crypticus* and *Eisenia fetida*) to three soil contaminants (phenanthrene, copper and sodium chloride) in artificial soil. Interestingly, we found the juvenile avoidance response was both more and less sensitive than adults. In addition, non-avoidance was observed by both juvenile and adult *Folsomia candida* and *Enchytreaus crypticus* when exposed to phenanthrene contaminated soils.

**RP074 Does the springtail *Folsomia candida* avoid free or total contaminants?**

*C. Teron, University of Saskatchewan Toxicology Centre; A. Gainer, University of Saskatchewan / Toxicology Centre / Soil Science, Toxicology; S. Siciliano, University of Saskatchewan / Department of Soil Science*

Avoidance toxicity tests are simple, rapid tests with ecological relevance. The avoidance response of soil invertebrates will vary depending on the exposure media it detects the contaminant, if it is detected at all. Thus, the avoidance response is largely linked to amount of free contaminant, whether it is in the soil gas phase (for volatile contaminants like some polycyclic aromatic hydrocarbons) or soil water phases (for heavy metals). The objective of this study was to assess the avoidance response of the standardized toxicity test soil invertebrate, *Folsomia candida*, to different levels of free contaminants. To vary the degree of free contaminants, we modified the peat content of artificial soil to 10% and 5%. Test contaminants included heavy metals (copper, cadmium), polycyclic aromatic hydrocarbons (phenanthrene, naphthalene and pyrene) and the standard soil toxicity test contaminant boric acid. The amount of free contaminants in metal contaminated soils was assessed using the Free Ion Activity Model and for polycyclic aromatic hydrocarbons contaminated soils activity was assessed using Fugacity.

**RP075 Quantification of Nano Zero-Valent Iron in Soil for Toxicity Testing**

*R. Akre, University of Guelph; W. Martin, B.A. Hale, University of Guelph / School of Environmental Sciences*

Nano zero-valent iron (nZVI) has been used for over twenty years in the remediation of groundwater and, more recently, soil. It can reduce the toxicity of contaminants such as polycylic aromatic hydrocarbons, pesticides, and heavy metals that are resistant to microbial degradation and weathering through degradation and immobilization. Before nZVI can be widely used in soil remediation efforts, toxicity testing must be done to compare the risk of the existing contaminants to the risk of the nZVI. Some literature exists on the toxicity of nZVI to soil biota, but these studies report nominal concentrations or reduction in bioactivity of a contaminant rather than measured concentration. This research endeavours to adapt a method of nZVI quantification from groundwater research that uses indigo disulfonate as a specific chemical redox probe. A standard curve is developed by reacting indigo disulfonate with known concentrations of nZVI to produce a colour change measured by ultraviolet-visible spectroscopy. This curve is then used to quantify nZVI in soil pore water extracted from nZVI amended soils. Toxicity testing on two species of soil invertebrates, *Folsomia candida* and *Eisenia fetida*, is then completed and combined with the method of measuring nZVI to express toxicity thresholds in terms of the realized dose in the soil.

## Novel Approaches for Understanding Diversity in Species Sensitivity to Chemicals

### RP076 A Multispecies Approach to Toxicity Testing With Nematodes

*A. Heaton, S. Glaberman, University of South Alabama / Biology*

Species differ across many levels of biological organization – each of which can affect how species respond to chemical exposure. Due to challenges in animal husbandry and resource availability, it is challenging to test many species in the lab at the same time to determine which aspects of species biology drive toxicity. Here, we show that multiple species of nematodes can be maintained and used for chemical testing with minimal resource input compared to many other types of organisms. Specifically, we tested several neurotoxic pesticides on four nematode species: *Caenorhabditis elegans*, *C. briggsae*, *Pristionchus pacificus*, and *Oscheius tipulae*. This model could be further expanded to include more – perhaps dozens – of additional species.

### RP077 High-Resolution Mass Spectrometry-based Metabolomics for Translating Exposure Effects Across Species

*M. Evich, ORISE at USEPA / National Exposure Research Laboratory; J.D. Mosley, USEPA / National Exposure Research Laboratory; J. Doering, NRC / USEPA / Mid-Continent Ecology Division; G.T. Ankley, USEPA / National Health and Environmental Effects Research Laboratory; K.A. Fay, General Dynamics Information Technology; D.L. Villeneuve, USEPA / National Health and Environmental Effects Research Laboratory; T. Collette, D. Ekman, USEPA / National Exposure Research Laboratory*

Chemical exposures often pose dramatically different health risks in fish depending on the species being investigated. These disparities are frequently due to differences in metabolism, excretion, exposure route, and a host of other species-specific traits. However, due to time and resource limitations, toxicity studies are often restricted to a small subset of species, and thus may fail to capture all potential risks. Unfortunately, many current approaches for measuring adverse effects are not designed for making evaluations across species. Among the ‘omics approaches, metabolomics is particularly well suited to cross-species assessments, because it does not require genome sequences. Furthermore, in addition to evaluating impacts on endogenous biochemicals (the metabolome), metabolomics is increasingly being used to monitor anthropogenic contaminants in exposed organisms, including their metabolism and excretion, thus expanding its use for understanding exposures as well as effects. Finally, a variety of biological matrices that can be sampled non-lethally contain rich metabolomic information allowing for: the repeated sampling of individuals, the use of larger sample sizes to better evaluate resident populations and the study of threatened or endangered species, for which lethal sampling is forbidden. Here we report the use of high-resolution mass spectrometry-based metabolomics to explore effects of exposure to the model aromatase inhibitor, fadrozole, in four fish species: Japanese medaka, fathead minnow, zebrafish and mosquitofish. As an initial focus, results of skin mucus are presented, reporting the measurement of distinct metabolomics profiles across these four species and the complex molecular processes observed in response to fadrozole exposure. In addition, skin mucus samples from other phyologenetically-diverse fish species were evaluated to determine the potential for using non-lethal metabolomics to monitor environmental exposures in highly disparate species. Easily detectable and species-specific metabolomic profiles were detectable in the skin mucus across the species analyzed providing strong evidence that species-specific adverse effects can be monitored using this metabolomics approach. As a whole, these investigations demonstrate that metabolomics responses may provide unique perspectives into cross-species exposure sensitivity, the molecular basis for this diversity and important non-lethal approaches for making such determinations.

### RP078 Metabolic fingerprint of pesticide exposure in fish to determine biological basis for species sensitivity

*B. Huerta, Michigan State University / Fisheries & Wildlife; J. Putnam, S. Lantz, USGS / UMESC; Y. Chung-Davidson, W. Li, Michigan State University*

Pesticides TFM and niclosamide are used to control the population of sea lamprey (*Petromyzon marinus*), an invasive fish species in the Great Lakes. However, non-target species such as lake sturgeon (*Acipenser fulvescens*), are affected under certain conditions by these pesticides. A lower detoxification capacity by glucuronidation can partially explain the selectivity of TFM to sea lamprey when compared with other fish species. However, lake sturgeon is also susceptible to TFM despite being able to detoxify it through glucuronidation. To elucidate the biological basis for sensitivity variation across these two fish species, we focused on metabolism to determine the mechanisms of toxicity. We hypothesized that exposure to TFM or niclosamide (or their mixture), even at sub-lethal levels, triggered biological perturbations that generated specific groups of characteristic metabolites, or metabolic fingerprint, in sea lamprey and lake sturgeon. In order to test this hypothesis, sea lamprey and lake sturgeon were exposed to two concentrations of TFM and niclosamide, one lethal and one sub-lethal. Fish head and gills homogenates were extracted by liquid-liquid extraction with a mixture of methanol, acetonitrile, and water (2:1:1, v/v). Samples were analyzed by UPLC/HRMS in a Xevo G2-XS quadrupole time-of-flight (Q-TOF, Waters) mass spectrometer. Several metabolic features that were differentially expressed in control and exposed samples were selected for each species and further investigated. Sea lamprey metabolic fingerprint was compared to that of lake sturgeon to assess differential sensitivity caused by metabolic processes. This approach allowed us to have a better understanding of the mechanisms involved in the dysregulation of metabolic pathways by TFM and niclosamide to uncover endpoints of toxicity for both fish species.

### RP079 Quantifying Ecosystem Responses to Anthropogenic Stress: An Environmental DNA (eDNA) Approach

*J. Feller, The Ohio State University / Department of Evolution, Ecology, and Organismal Biology; R.M. Swab, S.F. Spear, The Wilds Conservation Center; R.P. Lanno, Ohio State University / Department of Evolution, Ecology, and Organismal Biology*

To better understand ecosystem responses to anthropogenic stress, new biomonitoring methods are needed that assess biodiversity in a quick and cost-efficient manner. The emerging field of environmental DNA (eDNA) offers such an approach, as it can provide rapid, low-cost identification of the species in an area. To test the effectiveness of this new technology, eDNA will be collected from lakes along an acid-mine drainage (AMD) gradient within The Wilds Conservation Center (Cumberland, OH). Here there are several AMD-gradient watersheds, with each system often consisting of one AMD-affected headwater lake that filters downstream to several smaller lakes where pH returns to background levels. We previously observed fish recolonization downstream from AMD sources and plan to use eDNA sampling as a rapid, efficient tool to quantify biodiversity in fish, amphibian, and invertebrate communities along these AMD gradients. The goal of this proof-of-principle study is to estimate biodiversity and community structure at each lake using eDNA sampling and then compare these results with traditional ecological assessment methods (e.g., netting, electrofishing, invertebrate sampling). Water quality parameters (pH, metals, conductivity, dissolved oxygen) will also be assessed along the gradients for comparison to derived community structures. Our working hypothesis is AMD will reduce biodiversity and simplify community structure at lakes closest to the AMD source and that eDNA can be used successfully to detect these ecosystem changes. Results from this study will provide a wealth of species information beyond what is typically considered for remediation efforts. The extensive species data along a pollution gradient will allow for construction of site specific species sensitivity distributions (SSDs) for pH, metals, and other AMD characteristics. Knowing which levels of AMD correspond to desired community structures can help create AMD benchmark levels for any future attempts to restore affected lakes at The Wilds.

**RP080 Evaluation of microbial and chemical quality of ballast water collected from commercial ships entering Qatari waters**

*A.R. Al-Asmar, Qatar University; I. Goktepe, Qatar University / Biological and Environmental Sciences; B. Shomar, Hamad Bin Khalifa University*

The Arabian Gulf countries including Qatar heavily depend on the transfer of oil and gas via commercial ships. Therefore, introduction of pollutants and invasive species possibly present in ballast water carried by these ships has become an emerging environmental issue in recent years. Although there are set of rules and regulations for discharge of ballast water into the Arabian Gulf, not all ships comply with these regulations. Since Qatar became a full member of the International Maritime Organization (IMO) in 2018, it is required that the regulations and policies of ballast water disposal should meet the chemical and microbiological quality standards. This project aimed at investigating the microbial and chemical quality of ballast water samples collected from commercial ships entering Qatari waters. The ballast water samples were collected from 20 different ships and tankers at Qatari ports. The physiochemical (pH, salinity, conductivity, and TOC) and chemical parameters (total anions and cations, as well as metals) of each sample were analyzed using different instruments. Additionally, microbiological analysis for total aerobic microorganisms, generic *E. coli* and total fecal coliform, and *Vibrio* spp. were conducted using selective media. The presumptive colonies grown on selective media were identified using 16S rRNA technique. The results show that out of 20 samples tested, 15 ballast water samples had total aerobic microbial counts above the set limit of 2 $Log_{10}$/mL. In terms of fecal coliforms and *Vibrio* spp., the counts were also above the set limits of 2.39 and 1 $Log_{10}$/mL, respectively. The preliminary results indicate that these samples need to be treated before their discharge into Qatari waters. Based on 16S rRNA method, *V. parahaemolyticus*, *Enterobacter hormaechei*, and *Pseudomonas* spp. were the major pathogens identified in ballast water samples tested. The results of chemical analyses demonstrated that majority of ballast water samples (40-80%) had high concentrations of Zn, Sr, Cu, and Li. A positive correlation between Mo, V, and Mg and the total aerobic microbial and *Vibrio* spp. counts was determined at $P< 0.01$. These findings demonstrate the urgent need to properly treat ballast water before discharging into the Qatari waters in order to protect the marine ecosystem.

## Bridging the Gap Between Toxicity Method Challenges and Regulatory Compliance for Effluent and Ambient Toxicity Programs

**RP081 Improving Communication Between the WET Laboratory and Regulatory Authority**

*N. Love, S. Skigen-Caird, GEI Consultants, Inc.*

The standardization of whole effluent toxicity (WET) testing through the United States Environmental Protection Agency's (USEPA) 2002 methods resulted in an easy to follow method for laboratories to provide as consistent data as possible. Despite an improved control of variability, WET tests still depend on living organisms to respond to stressors in consistent ways, which may not always occur. When it comes time to explain variability in WET tests, or to request a regulatory conclusion on WET data, oftentimes regulators rely on state-specific, over-simplified, and sometimes dated implementation guidance that may not consider the full complexity of WET tests. Despite the EPA's attempts to improve understanding of WET methods through videos and other training formats, many regulatory authorities are under-funded, and over-worked, leaving little time for them to learn the intricacies of a method that they have never seen in action. Some regulatory agencies are lucky enough to have a specialist dealing with WET, but this is generally the exception. For the regulatory authorities tasked with making far-reaching conclusions on WET results, communication between the WET lab and regulator is key. By strengthening the knowledge exchange between the research community and regulators, more appropriate decisions can be made, improving trust and accountability for all parties. A 10-point method has been developed to improve communication between WET laboratories and regulators and is presented here.

**RP082 USEPA's Current *Ceriodaphnia dubia* WET Method and Other Applications to Better Understand Toxicity to Aquatic Life at Complex Sites**

*N. Love, GEI Consultants, Inc.; S. Skigen-Caird, GEI Consultants, Inc. / Ecological Division*

The *Ceriodaphnia dubia* whole effluent toxicity (WET) test method was refined by the United States Environmental Protection Agency (USEPA) in 2002 to provide better reproducibility of the data to ensure appropriate regulatory decisions were made based on the results of these tests. In many cases, the improved method has led to a protection of the receiving streams that was not reached before; however, in some cases the method does not provide a complete picture of the potential impacts on aquatic life. In these cases, additional methods should be used to evaluate the effluent to provide a complete picture of the effluent's impact on aquatic life. When used in combination, methods such as chemical analyses, instream biomonitoring, ambient WET testing, toxicity identification evaluation (TIE) testing, and alternate test species/new WET methods can help provide a more complete picture than standard compliance WET tests alone. Our evaluation of compliance WET tests and numerous additional methods for two sites has led to a more complete picture than the compliance WET tests alone. These methods, when used in a weight of evidence approach can provide a more accurate method of site evaluation. Making these additional methods more openly available for site evaluation through various regulatory approval pathways results in additional data available for use to better protect the environment. The lessons learned and suggested regulatory implementation are discussed.

**RP083 Effects of season and LED light on *Ceriodaphnia dubia* culture board survival, fecundity, and neonate reference toxicity test performance**

*R. Cooper, Arkansas State University; J. Bouldin, Arkansas State University / Ecotoxicology Research Facility*

Most incandescent light sales will be banned by 2020, so alternatives for use in culture organism light/dark cycles need to be investigated. Although they have a slightly higher up-front cost, LED lights last longer, are cheaper to operate over time, and produce less heat than incandescent lights, which is important for maintaining stable culture and test conditions. Over two three-month periods (February-April and August-October), we tested if there was a difference in *Ceriodaphnia dubia* survival and fecundity, as well as neonate performance in acute and chronic reference toxicity tests (NaCl) from culture boards maintained with incandescent or LED lights with comparable light intensity. We compared survival, 14-d average total neonates, number of broods, days to third brood of 8 or more neonates, and number of days to first brood for culture boards. Endpoints for reference toxicity tests included LOEC, EC50, IC25, and control group variation. We found no relative differences between any parameters tested within each test period, but that *C. dubia* performed better overall during the the August-October period. Therefore, we conclude that LED lights at comparable light intensity are a viable alternative to incandescent for *C. dubia* cultures.

**RP084 Amelioration of Low Hardness-Induced Effluent Toxicity to *Daphnia pulex* by Restoration of Effluent Hardness**

*S.L. Clark, R. Ogle, Pacific EcoRisk; P. Worland, Los Alamos National Laboratory*

Several treated effluent discharges from Los Alamos National Laboratory (LANL) are regulated under NPDES permits that require acute *Daphnia pulex* toxicity testing. While the Los Alamos region is surrounded by surface waters categorized as very hard (>181 mg/L), it can be considered an "island" with lower surface water hardnesses, typically in the moderately hard (60-120 mg/L) and hard (121-180 mg/L) range. However, the source of water used at LANL is not the local hard surface water, but rather is domestic tapwater (high-quality groundwater from the local aquifers via three water supply well fields, each of which has different hardness ranging from 29-56 mg/L [as $CaCO_3$]). This tapwater is used in LANL's facilities for a variety of applications. The wastewater for one area using this tapwater is collected into an influent tank at a typical hardness of 40-45 mg/L. However, subsequent treatment processes reduce the hardness to approximately 0.2-12 mg/L. Our laboratory evaluated 24 acute toxicity tests for that particular outfall and determined that there was an increase in mortalities associated with extremely low hardness levels with virtually no toxicity being observed when the hardness was >25 mg/L, which is consistent with several published studies indicating deleterious effects on other cladocerans at 5–50 mg/L hardness. As the LANL outfall discharges to 'harder' receiving waters, we recommended that LANL implement measures to increase the hardness of the effluent to the original source water levels, as some regulatory agency guidelines similarly call for the restoration of water hardness levels to those concentrations existing prior to the application of treatment processes that remove $Ca^{2+}$and $Mg^{2+}$. In order to evaluate the efficacy of such an adjustment, we performed side-by-side *D. pulex* toxicity tests of effluent and effluent restored to a hardness of 40-50 mg/L and consistently observed improved survival in the hardness-adjusted effluent. This study demonstrated that low hardness conditions can be a test interference for *D. pulex* tests, and that hardness amendments to match original source water levels can mitigate the apparent toxicity.

**RP085 Effect of *Ceriodaphnia dubia* Culture Hardness on Laboratory Control Test Performance**

*S.L. Clark, A.M. Briden, Pacific EcoRisk*

The US Environmental Protection Agency (USEPA) freshwater chronic toxicity manual (EPA-821-R-02-013) acknowledges that the type of water used for organism culture and dilution water is extremely important, and should come from the same source. The manual recommends that synthetic, moderately-hard water should be used as the culture and dilution water for testing performed to meet NPDES permit objectives. However, this guidance does not address how culture conditions may affect the test organism response. For example, it is unclear if toxicity testing performed with organisms cultured in moderately-hard water would have comparable biological responses to those obtained from organisms cultured in soft water. In order to address the concern of comparability of test results, we performed a study evaluating the outcome of the chronic *C. dubia* testing performed with organisms cultured in different hardness waters. In addition to our standard moderately-hard (80-100 mg/L) culture, we established a soft water (40-48 mg/L) culture that was acclimated to this culture water for several weeks. We then performed paired dilution water performance assessments using organisms cultured in moderately-hard and soft water. The results of this testing are presented, and ramifications for NPDES compliance determination are discussed.

**RP086 Assessing Food Preparation and Storage as Sources of *Ceriodaphnia dubia* Culture Quality and Chronic Test Variability**

*K.N. Prosser, Pacific EcoRisk / Quality Assurance; A.M. Briden, S.L. Clark, B.C. Jorgenson, Pacific EcoRisk*

Multiple inter-laboratory variability studies have identified significantly different outcomes for split samples tested using the chronic *Ceriodaphnia dubia* reproduction and survival test method (EPA 1002.0). Similarly, the culture performance for this species can also result in highly variable intra-laboratory testing. This variability is troubling and can result in diminished confidence in the testing protocol by regulated parties. In an attempt to determine, and subsequently control, the source of this variability, our laboratory has observed that food is the primary driver for *Ceriodaphnia* culture health and overall test performance. We suspect that, since food is the primary driver, food may also be a large contributor to the intra- and inter-laboratory variability associated with this species. In fact, the method allows for a significant amount of latitude for food type and preparation; this latitude may be a key driver of inter-laboratory variation. What then is the source of intra-laboratory variation, assuming the same protocols are used to acquire and administer each subsequent batch of food? Our study aimed to assess the potential sources of culture downturns and diminished test performance as it relates to *Ceriodaphnia* food, with focus on the most common food types used, *Selenastrum capricornutum* and YCT (yeast, Cerophyl, and trout chow). These sources include, individual food components (Could using different components alleviate poor performance?), vendors (Do vendor protocols always produce the best quality food?), laboratory supplies (Have the supplies been cleaned appropriately?), and age/freshness of the food batch (Does storage impact food quality?). Our study suggests that improvements to the method are necessary including standardized food preparation guidelines, time allowance for thorough QC vetting of each food type before expiration, and clearer survival and reproduction benchmarks for culture quality. For *Ceriodaphnia* culturing and testing, an ounce of prevention may save you a pound of cure .

**RP087 Evidence of Pathogen Interference and Pathogen Focused Treatments for Testing with *Ceriodaphnia dubia***

*N. Lynch, S. Vasquez, S.L. Clark, Pacific EcoRisk*

The USEPA manual for chronic toxicity testing only briefly addresses pathogen interference in tests performed with *Ceriodaphnia dubia* but has a far more detailed description of pathogen interference for the chronic *Pimephales promelas* test. This phenomenon is typically characterized by a flat concentration response curve, high inter-replicate variability, and possibly observations of microbes on live organisms. If the observed response cannot be eliminated with a change in dilution water, or a modification to the test design, and the pathogen interference has been confirmed after performing a re-test, the manual states, "the regulatory authority may allow modifications of the effluent samples or receiving water diluent to remove or inactivate pathogens… the effects of pathogenic bacteria and the effectiveness of the selected pathogen control technique must be confirmed by parallel and simultaneous testing of the technique with altered and unaltered samples". Our evaluations consisted of performing the USEPA freshwater 3-brood (6-8 day) survival and reproduction test with *C. dubia* to evaluate the efficacy of different treatments for pathogen removal. A variety of sterilization techniques were evaluated for the removal of pathogen interference symptoms. Testing was performed with POTW effluent which consistently exhibited pathogen interference, as previously mentioned. Results of these evaluations are summarized and discussed in the context of efficacy for pathogen removal.

## Bivalves as Indicators of Exposure and Ecosystem Health

**RP088 Contaminants of emerging concern monitoring by Great Lakes Mussel Watch Program**

*M. Edwards, NOAA National Ocean Service; K. Kimbrough, E. Davenport, NOAA; E. Johnson, NOAA / NCCOS / CCMA / National Centers for Coastal Ocean Science; A.P. Jacob, CSS / National Centers for Coastal Ocean Science*

The Great Lakes Mussel Watch Program utilizes a multi-matrix approach that deploys caged and in situ dreissenid mussels, polar organic chemical integrative sampler (POCIS), and semipermeable membrane devices

(SPMD) to spatially characterize the presence of contaminants of emerging concern in the rivers, harbors, connecting channels and offshore areas of the Great Lakes. By leveraging various resources to achieve common goals of CEC characterization, MWP investigated the occurrence and magnitude of a broad list of CECs in mussels collected from several Great Lakes locations with several land-use characteristics. Herein, we summarize the CEC data obtained between 2013-2017 and present the percent detections and magnitude in various matrices, and the spatial distribution of CECs with respect to land use. The results presented will serve as an initial assessment to characterize various suites of CEC that had the highest probability of being detected in tissue, and to identify what methods could be used in the future.

**RP089 Linear mixed model analysis of mussel metabolomics data**

*A.P. Jacob, CSS / National Centers for Coastal Ocean Science; E. Davenport, NOAA; E. Johnson, NOAA / NCCOS / CCMA / National Centers for Coastal Ocean Science; K. Kimbrough, National Oceanic and Atmospheric Administration; M. Edwards, NOAA National Ocean Service*

NOAA's National Centers for Coastal Ocean Science Great Lakes Mussel Watch Program (MWP) has been monitoring in the Great Lakes since 1992 using dreissenid mussels as indicator organisms. Through coordination with Great Lakes Restoration Initiative since 2010, the program expanded its monitoring activities in the region with the objective of providing data and information in making sound science based management solutions for the restoration of Great Lakes. The program incorporated newer approaches and techniques into its traditional chemical monitoring protocol to meet the evolving environmental challenges. Under the ongoing Great Lakes Action Plan II, MWP has initiated monitoring contaminants of emerging concern (CEC) and assessment of the effects of these emerging compounds on mussel health. A pilot study to monitor a broad suite of CECs and associated effects on bivalve health using metabolomics was undertaken in Maumee River in Lake Erie in 2016. Quantitative environmental metabolomics is an emerging high-throughput approach and requires systematic analysis of data to account for unwanted variation due to factors such as batch effects and confounding biological variation. Herein we present a multimodel inferencing approach using a linear mixed model analysis of mussel metabolomics data to identify significant differences in metabolomics concentrations among locations in the Maumee River. In addition, multivariate analyses of CEC data are used to characterize each location and link it to metabolomics data.

**RP090 Using metabolomics to connect exposure and effect in mussels**

*B. Chandramouli, SGS AXYS; E. Johnson, NOAA / National Centers for Coastal Ocean Science / NCCOS Mussel Watch Program; H. Butler, J. Cosgrove, SGS AXYS; E. Johnson, NOAA / NCCOS / CCMA / National Centers for Coastal Ocean Science; K. Kimbrough, National Oceanic and Atmospheric Administration; M. Mills, USEPA / National Risk Management Research Laboratory; A. Jacobs, NOAA National Ocean Service*

The Mussel Watch Program (MWP) has used bivalves to monitor contaminant levels and environmental health since 1986. In 2009, monitoring of legacy contaminants was expanded to the U.S. Areas of Concern to support the Great Lakes Restoration Initiative (GLRI). In 2015, Under Action Plan 2 of GLRI, MWP together with other federal partners began to address contaminants of emerging concern and explore the use of effects-based indicators. Bivalves, as generally immobile filter feeders that bioaccumulate contaminants, can serve as sentinel markers of both exposure and effect. The ability to observe bivalve metabolite profiles distinct to geographical locations and to combine this information with contaminant data provides a powerful tool to monitor this environment and to understand the biological impact of environmental changes. Understanding temporal effects in metabolome profiles can help inform exposure patterns and mussel biology. In this study, we analyzed the metabolomes of caged dresissenid mussels and clams at several great lakes sites including the Rouge, Detroit, and Maumee rivers (2016) and in the Milwaukee river (2017). A targeted metabolomics approach measured the concentrations of 222 metabolites including amino acids, biogenic amines, lipids, fatty acids, hexose and metabolites associated with energy pathways. Contaminant data for a large set of persistent organic pollutants and contaminants of emerging concern was also measured in mussels, and in the surface water. Multivariate and correlational statistical analyses were performed on the data to identify relationships between geographical sites and timepoints. Results from 2016 indicate that metabolite profiles could successfully reflect distinct site and species differences, and correlation analysis identified 94 contaminant measurements that correlated with 125 metabolites ($|r|>0.8$. Preliminary results from the 2017 collection time series experiments indicate that differences between sites can be seen as early as 5 days and consistently at 55 days. ANOVA indicated that metabolite changes show two patterns, early indicators of change which are observable by day 2, but that revert to the initial concentrations after more time, and those that change consistently, either up or down, between 2 and 55 days of exposure. Site-specific differences and biological significance of metabolite changes will be explored.

**RP091 Assessing genotoxicity in freshwater mussels in field and laboratory studies**

*E.A. Gilroy, Environment and Climate Change Canada / Aquatic Contaminants Research Division; S.L. Witzke, Green House Science; S.D. Campbell, Environment and Climate Change Canada; P. Gillis, Environment and Climate Change Canada / Aquatic Contaminants Research Division; J.S. Klinck, Redeemer University College / Ecotoxicology and Wildlife Health; S. de Solla, Environment and Climate Change Canada / Ecotoxicology and Wildlife Health Division*

A variety of chemicals can induce damage to the DNA of animals, which, if not repaired, can lead to a cascade of biological effects. First developed in the 1980s, the single cell gel electrophoresis assay – or Comet assay – is used to visualize and quantify DNA damage. In recent years, this approach has been used to evaluate DNA damage from exposure to specific chemicals, as well as from complex mixtures of waterborne contaminants, such as industrial or municipal wastewater effluents. DNA damage has been associated with reduced growth, abnormal development and reduced survival in a variety of aquatic animals; thus, the Comet assay could be used as a biomarker of exposure to conditions susceptible of increasing DNA damage in freshwater organisms. Over the last few years, we have developed the Comet assay in freshwater mussel hemocytes, for its application to field and laboratory studies: We completed field assessments of DNA damage Giant Floater mussels exposed to urban-derived contamination from southern Ontario watersheds, and where we observed a 35% increase in DNA damage in mussels from a heavily-urbanized site compared to an agricultural site. In a related study, we exposed mystery snails to sediments from Hamilton Harbour Area of Concern, contaminated with metals, PAHs, PCBs and dioxins. A 96-h exposure induced more than 35% increase in DNA damage in mystery snails *Cipangopaludina*, compared to control sediments. We performed several in vitro studies with data-poor priority chemicals (e.g., substituted phenyl amine antioxidants, naphthalene sulfonic acids), where we tested single chemicals using a combination of in vitro exposures with freshwater mussel hemocytes, and whole-mussel exposures. This research permitted to determine potential genotoxicity of priority chemicals. We assessed the genotoxicity of wastewater effluents and wastewater-influenced surface waters from large urban centres from southern Ontario, using in vitro laboratory studies, which showed that some wastewater effluents appear to contain genotoxic substances. The highlights of these studies will be discussed in the context of further relating DNA damage to other measures of organism health (e.g., tumours, growth, health), and potential applications for the development of water quality standards and procedures for the protection of aquatic life and ecosystem health.

**RP092 Determining freshwater mussel presence/absence in rivers using environmental DNA**

*E. Preece, M. Bryan, Robertson-Bryan Inc*

Freshwater mussels are excellent indicators of water quality and are particularly sensitive to ammonia toxicity. In California's Central Valley, state adopted water quality objectives (state term that is equivalent to federal "criteria") do not include an objective for ammonia. Rather, the state permits discharges of ammonia from Publically Owned Treatment Works (POTWs) and other sources based upon USEPA's national recommended water quality criteria for ammonia. Upon USEPA's promulgation of the 2013 ammonia criteria, it became important for state regulators to determine whether freshwater unionid mussels exist in individual water bodies into which POTWs discharge in order to determine whether USEPA's 2013 national recommended or "unionid mussel absent" ammonia criteria would be applicable to each discharge site for permitting under the National Pollutant Discharge Elimination System (NPDES). Thus, to establish proper ammonia effluent limits in NPDES permits, state regulators have requested POTWs provide information on the presence/absence of unionid mussels in the waterbodies where they discharge treated effluent. Environmental DNA (eDNA) from water samples is a powerful and rapid tool for determining presence, and hence occupancy of freshwater mussels without harming the surrounding ecosystem or the mussels themselves. In this study we developed and validated a quantitative polymerase chain reaction (qPCR) assay for the 3 freshwater mussel taxa that currently exist in California's Central Valley. We then introduced a cage of 20 *Gonidea angulata* into a riverine environment and collected eDNA samples at evenly spaced downstream intervals to determine how habitat type and distance from the caged mussels affected eDNA detection. Using occupancy modeling we determined that higher detection probabilities occur in riffle habitats compared to pool or run habitats. We also found surface samples work well for collecting freshwater mussel eDNA in riffle habitats, but are less likely to capture mussel eDNA in pools or runs. The maximum downstream distance at which the eDNA of the 20 placed *G. angulata* mussels were detected was 8 km. Our study demonstrates that eDNA is a reliable tool for determining the presence/absence of freshwater mussels in riverine systems, but that sampling should consider habitat type and season for the most effective results.

**RP093 Environmental Metabolomics for in situ Monitoring of Eastern Oysters Affected by Stressors from Point and Nonpoint Sources Along Coastal Georgia, USA**

*D.W. Brew, University of Georgia / Environmental Health Science; M. Henderson, USEPA / Office of Research and Development / National Exposure Laboratory; M.C. Black, University of Georgia / Dept of Environmental Health Science*

In the wild, eastern oysters (*Crassostrea virginica*) routinely adjust their physiology according to the numerous stressors present in their environment. However, the underlying biochemical processes, at the level of the metabolome, that represent these responses are poorly understood. Thus, we utilized untargeted GC-MS metabolomics to assess the metabolome of native oysters collected from oyster beds at the Brunswick River in Brunswick, GA and small tidal creeks at Sapelo Island, GA. Adductor muscle (n=5/site/month) was sampled every two months at each site from October 2014 – August 2015 and changes in the relative abundance of endogenous metabolites were determined via ANOVA with Fisher's LSD post-hoc testing. Putatively identified metabolites were associated with cellular energetics (i.e. citric acid and glyoxylate cycles as well as fatty acid and carbohydrate metabolism), amino acids, the urea cycle, cellular signaling and nucleotide metabolism. During colder sample months, there was an increased reliance on fatty acids and a decreased utilization of carbohydrates and amino acids as a source of energy. This suggests that oysters, during these months, are utilizing their nutrient reserves as a primary energy source. Supporting this, there was a decrease in N-acetyl glucosamine levels, which via its role in bivalve cilia beating, implies that the oysters were feeding at a reduced rate. With increasing water temperatures, the oysters appeared to utilize more readily available sources of energy, as there were large increases in citric acid cycle intermediates, carbohydrates and amino acids. There was also a concurrent increase in the abundance of the secondary signaling molecules, inositol and myo-inositol. These biochemical changes coincide with the normal spawning period of oysters in Georgia and imply that reproductive processes drive large-scale metabolomic changes. Changes in abundance for carbamic acid (glucuronidation substrate), aminomalonic acid, aminoadipic acid and glutamate (oxidative stress response), between the sample sites and months at both estuaries suggests that there are spatial and temporal differences in the stressors present that could also adversely affect the oyster's metabolome. This research highlights the utility of untargeted metabolomics in quantifying how seasonal changes in water quality affect the metabolome of an estuarine bivalve along coastal Georgia.

**RP094 Microplastics in Pacific Northwest Bivalves? Determining organism concentrations and estimating human consumption levels**

*B. Baechler, E. Granek, Portland State University / Environmental Science & Management*

The Pacific Northwest (PNW) supports a diversity of shellfish species which have been integral to PNW natural history and cultural heritage for millennia. Indigenous peoples in Oregon and Washington have subsisted on razor clams for centuries, and they are now a commercial and recreational staple. As human influences on the environment increase, many stressors and threats to these iconic species have emerged in the PNW and around the world. Microplastics are plastics smaller than 5mm in size that are intentionally manufactured or broken down from larger plastic pieces (Gall et al. 2015). These tiny fragments, pellets, and filaments originate from both marine and land-based sources, and frequently enter waterways through careless disposal, marine dumping, fishing gear loss, pollution, runoff, and wastewater. Marine organisms mistake microplastics for food items, which become incorporated into their guts, respiratory organs and tissues (Akpan 2014; Cole et al. 2011; Von Moos et al. 2012). While microplastics have been observed on PNW beaches, concentrations in seafood items have not been well-documented in this area, until a study was initiated in Oregon in 2017 by Baechler and Granek to quantify the types, concentrations, anatomical loadings, geographic distribution, and seasonal differences of microplastics in Pacific oysters and Pacific razor clams in Oregon and Washington. In order to estimate the potential human exposure rates of microplastics from razor clam consumption in the Pacific Northwest, a written survey was also administered to clammers on the Olympic Peninsula, Washington in April 2018. It aimed to identify frequency of razor clam consumption, preparation type, and number of individual razor clams consumed by respondents of varying demographics. Our findings will enhance the PNW's capacity to understand whether microplastics are a threat to coastal marine organisms or the humans who consume them. Highlighting the issue of plastics in the environment, and in important food sources, may ultimately lead to action on the management or policy level to reduce plastic transmission into the ocean.

**RP095 Platinum bio-accumulates and affects anti-oxidative biomarker profiles in the Zebra mussel (*Dreissena polymorpha*) after short-term exposure**

*S.J. Brand, North-West University / School of Biological Sciences / Environmental Sciences and Management; H. Erasmus, M. Labuschagne, North-West University; D. Grabner, M. Nachev, S. Zimmermann, University of Duisburg, Essen / Aquatic Ecology; V. Wepener, N. Smit, North-West University / Environmental Sciences and Management; B. Sures, University of Duisburg, Essen / Aquatic Ecology*

Platinum (Pt), one of the rarest elements on Earth, has excellent electrical conductivity and catalytic properties. Due to its exceptional characteristics, it has been widely applied in the automotive industry in catalytic converters and has also been utilized in the field of oncology due to its antineoplastic properties. Consequently, the wide-spread use of the precious metal has led to its increasing presence in the environment where the chemical composition of water and soil may alter its bioavailability and influence its uptake and accumulation in a host of living organisms – especially those found in the aquatic environments where pollutants tend to accumulate. Although previous studies have measured the presence of Pt in the natural environment, comprehensive characterisation of possible adverse effects following exposure of organisms to the metal remains elusive. To address this, a bivalve was identified as a relevant model to assess the accumulation of Pt and its subsequent biological effects in freshwater organisms. Zebra mussels (*Dreissena polymorpha*) were exposed to a range of Pt concentrations (0.1, 1, 10 100 and 1000 µg/L) for four days, after which bioaccumulation was measured and compared to alterations in biomarker profiles relevant to metal toxicity i.e. glutathione-S-transferase, catalase (CAT), malondialdehyde (MDA) and metallothionein (MT) content. During Pt exposure, bioaccumulation occurred in muscle soft tissue, accompanied by a decreased Pt concentration in the exposure media due to both biological and non-biological processes. At concentrations of >10 µg/L, Pt induced increased activity of antioxidant enzyme systems (GST; CAT) and a time-dependent trend of increased lipid peroxidation. Bioaccumulation of Pt was also associated with a concentration-dependent increase in Pt-MT, thereby offering support to anti-oxidative pathways by removing free reactive Pt. Although these effects occurred at levels higher than those present in the environment, it indicates that Pt has the ability to cause aberrancies in metal-associated biomarker profiles even at low concentrations following short-term exposure.

**RP096 Adverse reproductive impacts of multi-metal contamination on oyster *Crassostrea hongkongensis* in the Pearl River Estuary, China**

*N. Weng, HKUST Shenzhen Research Institute / Marine Environmental Laboratory; C. Lai, HKUST Shenzhen Research Institute; W. Wang, Hong Kong University Sci. Technol. / Department of Ocean Science*

As the largest estuary in Southern China, the Pearl River Estuary is seriously impacted by trace metal pollution as a result of rapid urbanization and industrialization. Despite of much evidence of metal contamination, little is known about the impacts on local marine life in this estuary. In the present study, the reproductive state of four populations of oyster Crassostrea hongkongensis, a dominant species in the Pearl River Estuary, was for the first time examined based on a one-year field study. The levels and types of metal accumulation in the oysters varied greatly among different populations. In particular, oyster populations from the more contaminated sites had a poor reproductive state in comparison with those from the relatively clean sites, as manifested by a lower gonad condition index, a decrease of gonad cover area, and more importantly, an imbalance of the sex ratios. The concentrations of Cu, Zn, Ni, Co and Pb in the gonad of the more contaminated oysters were much higher than those of the relatively clean oysters. Especially, gonad somatic index and gonad cover area of oysters during the breeding season were significantly and negatively correlated with the levels of gonadal metal accumulation. Our results indicated an adverse impact on the reproductive health of local oyster populations in a field environment associated with long-term multi-metal exposure.

**RP097 Baseline tissue concentrations of trace metals in three common bivalves in the Chinese coastal waters and worldwide**

*G. Lu, Hong Kong University of Science and Technology, Shenzhen Research Institute / Marine Environmental Laboratory; W. Wang, Hong Kong University Sci. Technol. / Department of Ocean Science*

Biomonitoring in aquatic system is one effective strategy to assess the potential risks of metal pollution and toxic effects. Bivalves have been extensively employed as biomonitors/sentinels of coastal pollution since the 1970s. Data mining of metal concentrations in the bivalve soft tissues needs to delve the deeper information and comparability in specific species and geographic environments. To explore the large-scale spatial pattern and baseline concentration of bioavailable metals, we analyzed the trace metals (including Cd, Cr, Cu, Ni, Pb, and Zn) in the soft tissues of oysters, mussels, and clams from different continents. Compared with the world historical metal databases, the median concentrations of Cd, Cr, Cu, and Zn in oysters along the Chinese coastal waters in 2015 were higher. However, the concentrations of Pb, Ni in oysters, as well as metals in mussels and clams were all lower than the world historical records. By conducting metal concentration frequency analysis, we modeled the baseline metal concentrations in these bivalves. We further modeled and checked the potential baseline concentrations of metals in these bivalves using a developed biokinetic/biodynamic model. Our comparisons suggested that the baseline concentrations of Cd, Cu, and Zn based on the concentration distribution frequency were comparable to those predicted by the biokinetic/biodynamic model. Our study provided a much more innovative method to establish the baseline metal concentrations in bivalves and biota environmental quality standards for the coastal management, biomonitoring, geochemical records/notes in the world.

**RP098 Physiological Response of Amblema plicata to Contaminants in the Guadalupe River Basin, Texas**

*S. Britton, A. Schwalb, Texas State University / Department of Biology; B. Jackson, Dartmouth College / Department of Earth Sciences; S. Wiseman, University of Lethbridge / Biology; C. Robertson, Texas Parks and Wildlife Department / Division of Inland Fisheries; J. Dutton, Texas State University / Department of Biology*

Aquatic pollution has contributed to the significant decline of unionid mussel populations throughout North America. In this study, adult threeridge mussels (*Amblema plicata*) were collected from 8 sites within the Guadalupe River basin and the concentration of 16 trace elements, including As, Cd, Cu, Hg, Se, and Zn were determined in gill and foot tissue using microwave acid digestion and ICP-MS analysis. In addition, water samples were also collected at each site to determine the concentration of nutrients (total nitrogen, total phosphorous, ammonium) and *E. coli* at each site. The physiological response of mussels to contaminants was quantified through biomarker analysis (lipid peroxidation, antioxidant capacity against peroxyl radicals, and total protein concentration) of gill tissue. The concentration of As, Cd, Cu, Se, and Zn was higher in the gills than in the foot at all sites, whereas Hg was higher in the foot at upstream sites and not significantly different from the gills at downstream sites. The Se:Hg molar ratios across sites ranged between 8 and 24 in the gill and 4 and 11 in the foot, indicating that Se may have a protective role against Hg toxicity. On average, Zn was found at highest concentration in gill tissue (395 to 488 µg/g dry wt), followed by As, Cu, Se, and Cd, and Hg was found at lowest concentration (0.061 to 0.187 µg/g dry wt). There was no significant difference in the concentration of Zn in gill tissue between sites, whereas there was a significant difference for As, Cd, Cu, Hg, and Se. There was no relationship between trace element concentrations and investigated biomarkers at each site, with the exception of a positive correlation between Co and Cd concentration and lipid peroxidation. Higher nutrient concentrations at upstream sites correlated with a) higher lipid peroxidation and lower antioxidant capacity against free radicals, indicating greater oxidative stress, and b) lower protein concentration showing reduced overall health. This is the first in-depth study on the impact of environmental contaminants on unionid mussels in Texas rivers and the findings conclude that mussels are exposed to a mixture of urban and agriculturally-derived contaminants.

**RP099 Sublethal toxicity and metal bioaccumulation of Corbicula fluminea near a coal-ash effluent**

*T.D. Thomason, UNC Charlotte / Department of Biological Sciences; T. Phan, University of North Carolina, Charlotte / Department of of Biological Science; A.H. Ringwood, UNC Charlotte / Department of Biology*

The storage of coal combustion residuals (CCR) in aquatic surface impoundments has been a common practice across the United States for decades. Typically these aquatic surface impoundments are designed to allow the upper portion of the ash-basin water column to be removed and emptied into nearby freshwater or coastal systems. This method of coal-ash storage and disposal creates the potential for chronic point-source inputs of toxic metals into vital aquatic resources. The goal of this study was to investigate the potential ecological impacts of coal-ash associated metals on a freshwater ecosystem adjacent to a decommissioned coal-ash basin on Mountain Island Lake, NC. Ecological impacts were quantified through chemical analysis of water and sediments, and the use of the freshwater clam *Corbicula fluminea* as a bioindicator species. Clams were allocated into cages and deployed in situ at five sites near the ash basin for a one-month duration. Site water and sediments were collected from each study site and analyzed for common coal-ash associated metals and particle size composition. One-week laboratory exposures were also conducted using field collected water and sediments. Study sites included two locations within Mountain Island Lake's coal-ash effluent mixing zone, two locations further downstream, and one upstream reference site. After exposure, clam soft tissues were assessed for coal-ash associated metal bioaccumulation using Atomic Absorption Spectroscopy (AAS) and clam health was assessed using a suite of sub-lethal cellular toxicity assays (lysosomal destabilization, lipid peroxidation, and micronucleus.) The use of these integrative methods can provide important insights into the temporal and spatial scales of biological toxicity of CCR associated toxicity while also serving to further validate *C. fluminea* as a suitable bioindicator species in freshwater systems.

**RP100 Long-term effects of zinc and a zinc-lead-cadmium mixture in water on juvenile freshwater mussels**

*J.L. Kunz, J.M. Besser, N. Wang, J.A. Steevens, USGS / Columbia Environmental Research Center*

Field studies have found that the abundance and diversity of freshwater mussels were reduced in metal-contaminated streams that drain the Tri-State Mining District (TSMD) of Missouri, Kansas, and Oklahoma. However, previous 4-week laboratory toxicity studies indicated that juvenile mussels were not among the most sensitive benthic taxa. We recently conducted a series of longer-term (12-week) toxicity tests to ensure that freshwater mussels are protected from injury from toxic metals in TSMD streams. In this study, we conducted water-only tests to evaluate the contributions of metals from stream water to toxic effects on juvenile mussels. A 2016 survey of TSMD streams found that dissolved zinc concentrations in surface water and interstitial water of mussel habitats frequently exceeded 10 ug/L at most sites downstream of mining activities. Lead and cadmium were detected in fewer samples, with these metals occurring at ratios of about 200 (Zn): 2 (Pb): 1 (Cd). We conducted 12-week tests with juvenile fatmucket *(Lampsilis siliquoidea*) to compare toxic effects of zinc exposure with the effects of a zinc-lead-cadmium mixture. Results of these studies indicated that toxic effects on juvenile mussels (reduced biomass) occurred at lower Zn concentrations in the metal-mixture test, with an EC20 of 7.2 ug/L (expressed as Zn) in the three-metal mixture, compared to 21 ug Zn/L for the Zn-only test. These results demonstrate that juvenile fatmuckets are highly sensitive to toxic effects of zinc and other metals at concentrations occurring in mussel habitats of TSMD streams. Ongoing studies in our laboratory will characterize the relative contribution of metals from TSMD sediment and overlying water to toxic effects on juvenile mussels, with the goal of establishing a reliable site-specific threshold for injury to mussel communities of the TSMD caused by metals.

## Impacts of Unconventional Gas Operations on Surface Waters, Soils and Groundwater – An International Perspective

**RP101 Development of conceptual models to screen deep groundwater contaminant pathways associated with coal seam gas chemicals**

*D. Mallants, CSIRO Land and Water; J. Kear, Z. Chen, CSIRO; S. Apte, Centre for Environmental Contaminants Research*

The focus of this paper is on developing and evaluating conceptual models with plausible fate and transport release pathways associated with coal seam gas (coal bed methane) development in Australia. The conceptual models developed throughout this study include the following elements: description of the contaminant source(s) relevant to deeper groundwater, including below-ground chemical leaks within the target coal formation and leaks in beneficial aquifers for several types of chemical, the likely fate and transport pathway of the chemical. hydrogeological conceptualisations of typical Australians CSG basins. description of the receptors (groundwater use and groundwater dependent ecosystems, including wetlands, springs, streams). statement of underpinning assumptions and hypotheses. Building on a literature review on plausible fate pathways, four plausible fate and transport release scenarios have been developed for which the likelihood for each of these scenarios is defined. The following scenarios are considered to represent a sufficiently broad range of flow conditions that may provide pathways for chemical transport into aquifers: Fracture growth into an overlying aquifer: This scenario considers hydraulic fracture fluid loss into an overlying aquifer. The scenario considers site conditions that favour height growth of a vertical hydraulic fracture upward towards and into a shallower aquifer. Fracture growth into a well through pre-fracturing permeability and new fractures: This involves two wells within the same coal seam, connected by a pre-existing hydraulic facture; Well rupture during injection: This scenario considers rupture of a cased well during a fracturing injection operation. If a cased part of the wellbore that passed through an aquifer were to rupture while a fracturing fluid was being pumped down the casing, the fracturing fluid could escape directly into the aquifer. Fracture growth into a fault: assessment of leakage potential via a fault that connects the coal seam to an overlying aquifer. For each of the above plausible failure scenarios that may lead to contamination of groundwater resources following hydraulic fracturing operations, the study determines i) if these failure scenarios are physically possible, and, ii) if so, under what properties and conditions, as well as iii) the envelope of possible behaviour.

**RP102 Chemical behaviour of fracturing fluid additives under high pressure and temperature conditions**

*A. Faber, Copernicus Institute / Utrecht University / Environmental Sciences; A. van Wezel, KWR Watercycle Research Institute / Chemical Water Quality and Health; P. Schot, Copernicus Institute / Utrecht University / Environmental Sciences; P. de Voogt, University of Amsterdam / IBED*

Environmental risk assessment relies on conceptual box models to predict chemical behaviour in the environment. These models are generally based on surface exposure routes and atmospheric physico-chemical parameters. However, during hydraulic fracturing, chemicals may be released deep underground, where high pressure and temperature conditions exist. One previous study on the downhole transformation of glutaraldehyde found that temperature, pH and salinity had the greatest effect on environmental fate. This study aims to broaden this information by assessing the environmental fate of a mixture of three fracturing additives under downhole conditions. 1,2-benzisothiazolin-3-one, phthalic acid and adipic acid were prepared together with crushed shale in 10mL Teflon tubes in an anoxic environment. These samples were then left under different temperature (25?C and 100?C) and pressure (1bar and 450bar) conditions for three days in order to compare degradation, transformation, dissolution and sorption under atmospheric conditions to those found under downhole conditions. Chemical sorption and transformation was assessed by accelerated solvent extraction followed by high resolution mass spectrometry. Dissolution and transformation in the liquid phase was determined by high resolution mass spectrometry. The hypothesis is that the chemical processes will be accelerated by the rise in temperatures. Pressure is not expected to affect these processes significantly. If downhole conditions have no to very little effect on chemical fate then the current conceptual box models may be used to adequately assess chemical exposure related to unconventional hydrocarbon activities. However, if downhole conditions have a significant effect on chemical fate then the models need to be revised for this purpose.

**RP103 Gas Chromatographic-Mass Spectrometric (GC-MS) Determination of Pyridine Bases in Environmental Samples**

*V.O. Olaoluwa, University of Hull / Chemical Engineering*

*Pyridine*, a volatile to semi-volatile organic material, is determined by Gas Chromatography (GC) using Mass Spectrometric (MS) detection in environmental samples such as river water and bottom sediment. A measured sample is collected in a beaker, and is preserved cryogenically (low temperature) with ice usually at $4^0$C to help prevent pyridine from becoming volatilised. The ensuing stage is the extraction process carried out by dissolving the sample in an organic solvent mixture of *n-Hexane* and *Dichloromethane* (DCM) in order to affirm absolute purification process. The pyridine bases are concentrated on a rotary evaporator and determined by Capillary Gas Chromatography-Selected-Ion-Monitoring (GC-SIM). The determination of a number of pyridine bases is done using a 15mm × 0.53mm Ion Detection (ID) Capillary Column followed by Selected-Ion-Monitoring (SIM). The detection limits were 10-15µg/L and percent recoveries from river water and bottom sediment were over 84%. This method is capable of simultaneous determination of sixteen pyridine bases with sufficient sensitivity and accuracy to be applicable to environmental samples.

**RP104 Heavy Metal Concentrations in Surface Water and Sediment from Soku Oil Field, Niger Delta, Nigeria**

*H. Omogoriola, Nigerian Institute for Oceanography and Marine Research / Fishery Resources; S.O. Ayoola, Univeristy of Lagos / Department of Marine Science*

Oil industry activities such as exploration, transportation, storage, use and disposal, as well as oil spills are sources of major contamination problems in Niger Delta, which have significant deleterious effects on aquatic organisms. The objective of this study was to evaluate the impact of crude oil spillage and production activities in Soku oil fields. The sampling stations are Soku Gas Plant (SGP), Soku Flow Station (SFS), Soku Gas Plant Town (SGPT) and Abonemma town (ABT) which is reference station. mfor Cadmium, Lead, Nickel and Vanadium respectively. The heavy metal concentrations in sediment samples also ranged between 0.018mg/l (WT) and1.676 mg/l (SFS), 1.057 mg/l (WT) and 3.985mg/l (SFS), 0.040mg/l (WT) and 0.611mg/l (SFS), 0.004mg/l (WT) and 0.210mg/l (SFS) for Cadmium, Lead, Nickel and Vanadium respectively. The mean concentrations of Cd, Pb, Ni and V in Soku Oil Field are 0.018mg/l, 0.054mg/l, 0.008mg/l and 0.003mg/l for surface water and 0.849mg/l, 2.815mg/l, 0.310mg/l and 0.124mg/l respectively. The decreasing trend of metals in surface water and sediment were Cd>Pb>Ni>V and Pb>Cd>Ni>V respectively. These results showed that heavy metals concentrations in sediments were high than that of water. Also, heavy metals concentrations in water and sediment were above the permissible limit by FEPA/DPR, USEPA and WHO. The areas sampled had high heavy metals concentrations that are likely to crude oil spillage and production activities. It could be concluded that the Soku Oil Field is heavily polluted which could have negative impacts on aquatic organisms inhabit the area.

## Water and Land Management to Reduce Methylmercury Bioaccumulation

**RP105 Trends in fish mercury concentrations within a newly restored tidal marsh at Hamilton Airfield**

*M. Herzog, J.T. Ackerman, A. Hartman, M. Toney, USGS / Western Ecological Research Center*

The Hamilton Army Airfield, in San Pablo Bay, California, was recently restored to tidal action in 2014, and methyl mercury production and bioaccumulation was identified as a potential impact of the tidal marsh restoration. From 2013-2016, we analyzed 331 stickleback for total mercury concentrations from at least 9 sites each year: 2 sites within Hamilton's tidal wetland area, 2 sites within Hamilton's western seasonal wetland, 3 sites within Hamilton's southern seasonal wetland, and 2 reference sites at the Sonoma Baylands. Total mercury concentrations in stickleback were higher at Hamilton than at the Sonoma Baylands reference site in 2013, marginally higher in 2014, and not significantly different in 2015. However, in 2016 stickleback mercury concentrations at Hamilton were once again higher than at the control site. In 2014, stickleback mercury concentrations increased at Hamilton (23% increase) and the Sonoma Baylands reference site (63% increase) relative to 2013 (pre-breach). In 2015, stickleback mercury concentrations showed little change at Hamilton (-1%) relative to 2014, but concentrations at Sonoma Baylands continued to increase during the same timeframe. In 2016, stickleback mercury concentrations increased by 39% at Hamilton, however there was no change in mercury concentrations within stickleback collected at Sonoma Baylands. At Hamilton, stickleback mercury concentrations trends differed depending on the habitat type, increasing by 24% at the tidal wetland, increasing 123% at the southern seasonal wetland, and decreasing by 49% at the western seasonal wetland, between the pre-breach sampling period (2013) and the first post-breach sampling event (2014). These results suggest both localized changes at the Hamilton restoration site, likely related to the breaching event, as well as regional inter-annual variability in fish total mercury concentrations. In general, stickleback mercury concentrations at Hamilton (0.46 µg/g dw; N=331 fish, 2013–2016) were considered high in mercury contamination and comparable to the high concentrations of mercury we have observed in stickleback collected in other mercury contaminated managed ponds, mudflats, and sloughs in the South San Francisco Bay (means range from 0.41-0.45 µg/g dw).

**RP106 Mercury contamination in birds helps guide wetland management decisions for the South Bay Salt Pond Restoration Project**

*J.T. Ackerman, M. Herzog, A. Hartman, USGS / Western Ecological Research Center*

Mercury contamination is elevated within the San Francisco Bay, California and the estuary is a hotspot for mercury contamination of birds within western North America. The South Bay Salt Pond Restoration Project in San Francisco Bay is the largest tidal wetland restoration project on the West Coast and is in process of converting >15,000 acres of former salt ponds into tidal marsh and managed wetland habitats. This large-scale wetland restoration may change the distribution, bioavailability, and bioaccumulation of methylmercury within the estuary and therefore bird mercury concentrations are being monitored to evaluate the effects of management actions. We documented a rapid and substantial response of mercury contamination in Forster's tern eggs following wetland restoration actions. Specifically, egg mercury concentrations increased by 63% (+0.90 µg/g fww) the year after wetland restoration actions, but were similar between years at reference wetlands (-9% or -0.12 µg/g fww). The increase in Forster's tern egg mercury concentrations to a mean of 2.34 µg/g fww in restored wetlands were several times higher than common toxicity benchmarks. The increased mercury concentrations in Forster's tern eggs occurred in the year immediately following the restoration actions, but egg mercury concentrations thereafter declined to ambient levels within 2 years. In contrast, the change in American avocet egg mercury concentrations immediately after wetland restoration actions (-1% or -0.00 µg/g fww), relative to reference wetlands (+1% or +0.00 µg/g fww), was negligible. Bird egg mercury concentrations in restored wetlands remain among the highest in San Francisco Bay and long-term trends in egg mercury concentrations remain elevated. Mercury contamination in birds may be acting as an additional stressor at a time when breeding bird populations are declining in San Francisco Bay and managers and stakeholders are attempting to reverse these population declines by constructing additional nesting islands within wetlands.

**RP107 Sediment Incubations to Assess Mercury Methylation Dynamics in a Hyper-eutrophic Reservoir**

*B. Fuhrmann, University of California ,Merced; M. Beutel, University of California, Merced / Civil and Environmental Engineering; M. Marvin-DiPasquale, USGS / Water Mission Area; S. Brower, J. Pasek, City of San Diego Public Utilities Department; P. O'Day, University of California, Merced*

Inorganic mercury (Hg), predominantly from widespread atmospheric deposition, but also from point sources including mine and industrial sites, is transformed to methylmercury (MeHg) by anaerobic bacteria in oxygen-poor water and sediment. Regulatory measures aimed at reducing MeHg in fish tissue were recently enacted in California and 131 reservoirs are currently identified as Hg impaired. While there is regulatory pressure on reservoir managers to lower fish tissue MeHg concentrations, food web dynamics are complex and there is uncertainty as to how to accomplish this goal. This study focuses on a Hg impaired, hyper-eutrophic reservoir in San Diego, CA where thermal stratification results in the accumulation of dissolved MeHg in the reservoir hypolimnion from April to October. This presentation will present the results of laboratory incubation experiments conducted monthly with reservoir sediment and bottom water. The experiments are designed to asses which conditions are favorable for Hg-methylation, which conditions suppress methylation, and how this changes with time. Incubation treatments include the use of selective bacterial inhibitors, organic substrate amendments, inorganic mercury, and redox manipulation to assess the key drivers and microbial groups involved in MeHg production in this system. Preliminary results suggest that a variety of anaerobic organisms are involved in both methylation and demethylation throughout stratification and that the system is carbon limited soon after stratification begins, but this limitation is quickly met after surface eutrophication results in organic matter deposition to the sediment. These results will be discussed in association with potential approaches to repress MeHg accumulation in fish tissue. With a more comprehensive understanding of MeHg cycling at the profundal sediment-water interface, reservoir managers will be better able to develop effective management strategies aimed at repressing MeHg bioaccumulations in lakes and reservoirs.

**RP108 Seasonal methylmercury dynamics in and export from the Hells Canyon Reservoir Complex, Idaho and Oregon, USA**

*A. Baldwin, USGS / Idaho Water Science Center; D.P. Krabbenhoft, G. Clark, USGS; J. Naymik, R. Myers, C. Hoovestol, Idaho Power Company; C. Eagles-Smith, USGS / Forest and Rangeland Ecosystem Science Center; M. Marvin-DiPasquale, USGS/ Water Mission Area; B. Poulin, USGS*

Anoxia in the hypolimnion of lakes and reservoirs can promote the conversion of mercury (Hg) to the more toxic methylmercury (MeHg) form. In the 200-km Hells Canyon Reach of the Snake River along the Idaho-Oregon border, three deep (up to 90 m) reservoirs seasonally stratify for months at a time, creating anoxic conditions that promote MeHg production in the hypolimnion. As a result, both Idaho and Oregon have listed this reach of the Snake River as impaired for Hg, with fish-tissue samples regularly exceeding Idaho's human health fish tissue criterion of 0.3 mg/kg wet weight. In 2014, the U. S. Geological Survey and Idaho Power Company initiated a collaborative investigation of Hg cycling and fate in the Hells Canyon reach. Primary research questions for this project include understanding the mechanisms promoting MeHg production in the hypolimnion, and the fate of the MeHg accumulated in the hypolimnion subsequent to reservoir destratification and mixing. To help answer these questions, the mass loadings of Hg and MeHg into, within, and out of the Hells Canyon complex of reservoirs were estimated using discrete water-quality data and streamflow into and out of each reservoir. Water samples were collected biweekly from four reservoir inflow/outflow locations between 2014 and 2017 and were analyzed for dissolved and particulate Hg and MeHg. Streamflow data collected continuously at the inflow and outflow of each of the three reservoirs were used to compute mean daily streamflow values during the sampling period. Using the R software package rloadest, regression models were developed to relate instantaneous Hg and MeHg loads to daily streamflow and seasonal variables. Loads were computed at various time steps over the sampling period to estimate the mass balance for each reservoir in the Hells Canyon Complex and for the complex as a whole. Results indicate that Hg inflow is ~2.9x greater than outflow, and MeHg inflow is ~1.6x greater than outflow, despite clear seasonal production and export of dissolved MeHg from the reservoir complex. Thus, overall, the reservoirs act as Hg and MeHg sinks. Findings from this study are intended to help manage the Hells Canyon Complex to minimize downstream export of Hg and MeHg.

**RP109 Mechanistic Simulations of Total and Methyl Mercury in the Yolo Bypass, a Mercury-Contaminated Floodplain**

*R. Harris, D. Hutchinson, Reed Harris Environmental Ltd.; C. DiGiorgio, D. Bosworth, State of California / Department of Water Resources; P. Sandhu, State of California; M. Stephenson, California State University / Moss Landing Marine Laboratories; G. Gill, Pacific Northwest National Laboratory / US Dept of Biosciences; W. Heim, California State University / Moss Landing Marine Laboratories; D. Schoellhamer, P. Work, USGS; M. Bahia, State of California; R. Jones, HDR Inc*

The Sacramento-San Joaquin Delta in California is impacted by legacy mercury contamination from upstream historical mining. Microbial activity in downstream aquatic environments can convert inorganic mercury to methylmercury (MeHg), a toxic and readily bioaccumulated form of mercury. To protect human and wildlife health, the Delta Mercury Control Program was adopted in 2011. One the requirements of the Program is that MeHg loads from an area known as the Yolo Bypass be reduced from 100 g $yr^{-1}$ to 22 g $yr^{-1}$, a 78% reduction. The Yolo Bypass is a 24,000 ha floodplain used for flood control for the Sacramento River. The Yolo Bypass is also used for a variety of farming and wetland management purposes, and experiences seasonal wetting and drying cycles. The California Department of Water Resources (DWR) is required to evaluate whether operational changes or other management strategies could be implemented to reduce open water MeHg production. A mechanistic model of mercury cycling (D-MCM) is being applied in 2D mode to the Yolo Bypass to identify options to meet regulatory requirements. A 47 cell model grid was used to represent the Bypass in simulations from 1997-2012. Different land uses were assigned to various areas. Hydrodynamics were provided by TUFLOW, a 1D/2D hydrodynamic model. Soil/sediment resuspension rates were estimated by combining hydrodynamic predictions with USGS erosion microcosm experiments. Water column and sediment/soil concentrations of total mercury and MeHg are being measured by DWR and the Moss Landing Marine Laboratories (MLML). Pore water mercury fluxes and the effects of vegetation senescence on MeHg production are also being studied experimentally by MLML to provide information for modeling. Results of the model calibration to existing conditions will be presented, including major sources, sinks, and concentrations of total mercury and MeHg in the Yolo Bypass. Results from the Yolo Bypass simulations are also being used in a broader effort to simulate mercury in the overall Delta.

**RP111 Long-range atmospheric deposition of toxic heavy metals within Kejimkujik National Park, Nova Scotia**

*S. Roberts, Environment Climate Change Canada / Aquatic Contaminants Division; J. Kirk, Environment and Climate Change Canada / Global Tox; J. Wiklund, University of Waterloo; D.C. Muir, Environment and Climate Change Canada / Aquatic Contaminants Research Division; F. Yang, A. Gleason, G. Lawson, Environment and Climate Change Canada*

Kejimkujik National Park, in Nova Scotia, Canada, is a sensitive region for heavy metal contamination, such as mercury, in part due to long-range atmospheric deposition from global and regional industrial regions. The region is remote from industrial centres, but is downwind of major pollution sources in North America and Canada, and historically had numerous gold mining sites. The region has also experienced anthropogenic acidification from sulphate deposition over the 20th century, which has resulted in limnological conditions favourable for mercury (Hg)

methylation within Kejimkujik lakes. Kejimkujik is therefore known to be a hotspot for methylmercury (MeHg) bioaccumulation and biomagnification, with the highest Hg concentrations detected within common loon (*Gavia immer*) populations across Canada and North America. Due to a paucity of long-term atmospheric deposition monitoring in this region, little is known about the response of Kejimkujik lakes to multiple changing global, regional, and local atmospheric Hg and metals sources. Here we use multiple lake sediment cores to reconstruct anthropogenic depositional fluxes of 45 elements, including Hg and heavy metals of concern for the last ~150 years. Results show that Kejimkujik lake sediments are highly enriched in Tin (Sn), Antimony (Sb), Lead (Pb), Mercury (Hg), Bismuth (Bi), Silver (Ag) and Tungsten (W), with current metal concentrations being > 2-fold greater than natural baseline/pre-industrial levels (prior to ~1800 AD). Modern depositional Hg fluxes matched well with precipitation data for the region, with wet deposition measurements and sediment derived fluxes ranging between 5.5 to 7.8 $\mu g/m^2$ and 8.2 to 9.3 $\mu g/m^2$ respectively, between 1990 AD and 2010 AD. Furthermore, lake sites closest to historic gold mining sites show spikes in Ag, Cadmium (Cd), Sb, Thallium (Tl), Zinc (Zn) and, W during the operative period of the mines (~ 1880 AD and 1950 AD). Landscape scale fluxes will also be calculated, and the influence of the catchment area on metal deposition within these Kejimkujik lakes will be explored, along with acid mobility of certain metals within the sediment record. Sediment-core reconstructed atmospheric deposition values combined with biological monitoring data from sensitive regions, such as Kejimkujik National Park, will be useful for predicting the impacts of the Minamata Convention on Hg deposition to lakes and Hg levels in biota.

## Modeling Oil and Chemical Transport in the Water Column After Spills

**RP112 Modeling Water Column Exposure Dynamics from Oil Spills: Model Validation for the Deepwater Horizon Oil Spill**

*D.P. French-McCay, M. Horn, D. Crowley, D. Mendelsohn, RPS Ocean Science*

Oil spill modeling of the 2010 Deepwater Horizon discharge was performed to evaluate the fate and concentrations of the oil and its components in subsurface and surface waters of the Gulf of Mexico, including consideration of the time-varying applications of dispersants at the discharge location at depth and on the surfaced oil. The oil fate model Spill Impact Model Application Package (SIMAP) was used to estimate rise rate of oil droplets released at depth, oil surfacing, weathering (evaporation, dissolution of oil constituents, degradation, emulsification) of oil droplets and surfaced oil, entrainment of surface oil, movements of oil droplets and dissolved components, adherence of oil droplets to suspended particulate matter (SPM), adsorption of semi-soluble hydrocarbons to SPM, sedimentation, and stranding on shorelines. As sampling in deep water (>40 m) during April-July 2010 was primarily performed within 25 km of the spill site, model predictions below 40 m were compared to field data from within a 25 km by 25 km box centered on the wellhead. Concentrations of soluble and semi-soluble hydrocarbon components predicted by the model agreed well with chemical measurements when compared as frequency distributions within varying depth zones of the water column. The results showed that the soluble hydrocarbons primarily dissolved near the release depth, while semi-soluble compounds (e.g., PAHs) were partially dissolved at depth and as droplets rose. Because the sampling in the upper 40 m was not synoptic or sufficiently representative of the entire modeled domain, a comparison of the modeled to observed concentrations was performed using samples collected within the upper 10 m of the 25 km by 25 km box centered on the wellhead between April 22 and July 15 of 2010. Concentration measurements below 0.1 ug/L total PAHs were considered biased due to many constituent concentrations being below method detection limits. The model predictions were that about 70% of the water samples would have concentrations >0.1 ug/L total PAHs, whereas about 80% of the available samples in upper 10 m of the comparison area exceeded this threshold.

**RP113 Simulating Chemical Dispersant Application to a Deep Sea Blowout**

*V. Kolluru, M.J. Fichera, ERM, Inc.*

During the Deepwater Horizon event, chemical dispersants were injected into the flow of oil from the reservoir released into the ocean at the seafloor from the broken blowout preventer through the fallen riser pipe. The objective of the dispersant application was to reduce the droplet sizes of the liquid oil before reaching the water surface. Decreasing droplet sizes increases the surface area of the droplets and thereby increases the rate of weathering and limits the amount of oil reaching the surface that can lead to near-surface biological injury and shoreline impacts. Modifications were made to the Chemical / Oil Spill Impact Module (COSIM) of the Generalized Environmental Modeling System for Surfacewaters (GEMSS®) to extend the existing dispersant application module to simulate the application of subsurface dispersants and its effect on droplet sizes. The surface dispersant module in COSIM was developed using laboratory and field-tested droplet distribution algorithms that depend on pipe diameter of the release, oil properties, blowout jet velocity, Weber number (ratio of inertial to surface tension force), dispersant effectiveness and the droplet distribution curve. In this investigation, the chemical dispersant module was tested on hypothetical blowouts to demonstrate the impact of dispersants on the weathering and the overall mass balance of the simulated oil spill. Modeling results were compared between scenarios made with and without chemical dispersants. Ranges of initial droplet sizes were studied to track the pathways and speed of the rising oil plume while oil dissolves, degrades, and forms a slick on the surface. Variations were also tested for the effectiveness of the dispersants with varying depths of the blowout, altering the time for oil to rise through the water column before formation of a slick.

**RP115 Use of Hydrocarbon Blocks for modeling the transport, fate and exposure of complex mixtures such as crude oils**

*J. Kubitz, Cardno; M.J. Fichera, ERM, Inc.; Y.B. Atalay, S.M. Bartell, Cardno Entrix*

Petroleum products are complex mixtures of many compounds. It is impractical to resolve, quantify and model each individual constituent in a crude oil or even a refined product that has a more consistent composition. It is quite practical, however, to identify specific groups of compounds that have similar physical and chemical characteristics and model those. These groups of compounds have been referred to as “cuts” in the past. As analytical techniques for characterizing petroleum mixtures have become more detailed, it has become more practical to characterize oils with a greater number of groups, which are commonly called “hydrocarbon blocks”. In this presentation we will review a method for organizing the information from readily-available chemical analyses for a petroleum mixture into a suite of approximately 20 hydrocarbon blocks that can be readily modeled with the Chemical Oil Spill Impact Module (COSIM) and other oil spill models. We will also discuss how these hydrocarbon blocks can be used to compare modeled data with measured data from field samples, to facilitate field verification.

**RP116 Modeling the photo-enhanced toxicity of organic compounds at the sea surface requires a dual dose approach**

*J. Kubitz, Cardno; Y.B. Atalay, S.M. Bartell, Cardno Entrix*

The toxicity of some polycyclic aromatic hydrocarbons (PAHs) has been observed to increase markedly when organisms are exposed to ultraviolet (UV) light, which is commonly referred to as photo-enhanced toxicity. There is also evidence that a component of sunscreen formulations may also exhibit photo-enhanced toxicity, and could be adversely affecting coral reefs. The severity of adverse effects depends on both the exposure to individual PAHs and the UV irradiance, which requires both doses to be characterized. In this presentation we will outline the conceptual model of the processes that are involved in photo-enhanced toxicity and describe the computational algorithms that are available for quantifying exposures. We will review the strengths and weaknesses with each algorithm, assess the uncertainties associated with the current state of the science, and recommend areas for future research and development in the quantification of photo-enhanced toxicity.

**RP117 Adsorption of crude oil on activated carbon**

*D.O. Adesina, University of Lagos, Department of Chemistry*

The presence of dissolved crude oil in water poses significant environmental hazards to aquatic lives. Components of dissolved oil, BTEX which are carcinogenic can cause cancer after a long time of exposure. Activated carbon was used to remove both dissolved and dispersed oil in simulated produced water. It was conditioned to provide good oil uptake in its natural form. Investigations carried out include the effects of parametric variations of different adsorbate and time, on the adsorption of crude oil. Sorption experiments with the activated sorbent showed that Temkin isotherm ($R^2$= 0.9548) fitted better than Fruendlich and Langmuir isotherm. Several kinetic models were tested and it was discovered that the sorbent followed pseudo-second order sorption kinetics. The value of Qe deduced from the slope of the curve was 1.01 mg/g and the value of rate constant ($k_2$) was found to be 3.35 $g.mg^{-1}min^{-1}$. This result showed that activated carbon is a good sorbent for crude oil removal in produced water. It will provide a way of cleaning oily contaminated water environment thus safeguarding human health, aquatic lives, and soil fertility.

**RP118 Parting the Tides: Determining Oil Concentration on the Hudson River's Surface Through Liquid-Liquid Extraction**

*C. Renaud, Marist College / Department of Environmental Science; Z. Gagnon, Marist College / School of Science*

The Hudson River is a vital region that not only is home to many essential aquatic ecosystems but is also a water source for public communities in the surrounding area. Protecting this resource is of utmost importance. However, the U.S. Coastguard's recent Hudson River Anchorages Proposal aims to establish 43 new anchorages at 10 sites along the Hudson River. These anchorage sites would heavily increase barge traffic and crude oil transport along the River which is a major concern because these barges, by design and by defect, leak crude oils into the Hudson River. Prior research on water quality safety standards suggest that oil and grease concentrations as low as 0.1 mg/L can be lethal to some of the more receptive aquatic organisms. For drinking water, the Sri Lankan Standards Institute recommends that oil contamination not exceed 0.2 mg/L. Assessment of oil contamination is one of the first steps in determining the severity of the issue. Through this research, an efficient and cost-effective method was developed to determine oil concentration on the surface of the Hudson River. Samples were collected from the River surface in half mile increments away from the Poughkeepsie Waste Water Treatment Plant. The method in question involves using the solvent n-hexanes in liquid-liquid extraction of the oil contaminants, and then comparing the weight of 10 mL n-hexanes solutions before and after extraction. In the preliminary trials of this method, it was determined that the oil concentration on the Hudson River surface exceeded the maximum health safety standards for aquatic life and for public consumption, with the average oil concentration being 1.324 mg/L. This research will aid in the communication of the dire situation that the Hudson River is already facing in order to demonstrate that the River's health cannot afford more barge traffic.

## Adverse Effects of Chemicals on the Microbiome

**RP119 Understanding how dietary exposure to single-walled carbon nanotubes may alter the composition and functionality of the gut microbiome**

*A. Wormington, A. Buerger, S. Robinson, University of Florida / Environmental and Global Health; C. Lavelle, USEPA / GED; T. Ngo, University of Florida / Environmental and Global Health; K. Kroll, University of Florida; N.D. Denslow, University of Florida / Physiological Sciences; T. Sabo-Attwood, J.H. Bisesi, University of Florida / Environmental and Global Health*

The efficiency of the gastrointestinal system is heavily influenced by the community of microbes lining the gastrointestinal tract (aka "gut microbiome"), which plays a role in metabolism, nutrient absorption, and immune function. Despite the essential role of the gut microbiome in maintaining gastrointestinal homeostasis, interactions between toxic chemicals and the microbiome are not well understood. Carbon-based nanomaterials, especially single-walled carbon nanotubes (SWCNTs), have emerged as a class of contaminants of particular concern due to their high production volume and increased likelihood of environmental release. In aquatic environments, these hydrophobic nanomaterials likely settle onto sediments and associate with organic matter, where they may enter the food chain through dietary routes. Recent evidence from our group has found that, while SWCNTs themselves are not physically taken up by the gastrointestinal system, they can induce molecular changes at the gastrointestinal interface, altering the regulation of genes encoding for the peptide transporters, *pept1* and *pept2,* and the satiety hormone cholecystokinin. These findings indicate that SWCNTs can interact with the gastrointestinal environment; however, the specific interactions and their consequences remain unclear. In order to investigate how dietary exposure to SWCNTs may change the gastrointestinal environment, we conducted a 3-month feeding study using largemouth bass (*Micropterus salmoides*), a top level freshwater predator likely to be exposed to SWCNTs through dietary routes. Fish were exposed to 2.5 mg/kg SWCNT-coated food and fed once daily to satiation. At 0, 4, and 11 weeks of exposure, guts were removed, sectioned into proximal, middle, and distal parts, and stored at -80 for analysis. Next-generation sequencing followed by PiCrust modeling was used to identify differences in the composition and functionality of the gut microbiome associated with dietary exposure to SWCNTs. Additionally, a combination of analytical, and molecular methods where used to observe SWCNT-induced changes in endpoints such as gut inflammation and bile interactions. Data from this study will increase our understanding of impacts of chemicals on the gastrointestinal environment and help elucidate potential environmental risks associated with exposure to single-walled carbon nanotubes.

**RP120 Effects of oil on gut and gill microbiome of three pelagic Gulf of Mexico fish**

*M. Wigren, Purdue University; M. Rodgers, E. Jones, University of Southern Mississippi / Gulf Coast Research Laboratory; R.J. Griffitt, University of Southern Mississippi / Coastal Sciences; M.S. Sepulveda, Purdue University / Department of Forestry and Natural Resources*

The microbiome of fish is a crucial part of maintaining host health, and helps with acquiring nutrients in digestion, developing the immune system, and protecting the host from opportunistic pathogens and other environmental stressors. Microbial communities can vary in species composition and have functionally different roles depending on their location within the host, including the gastrointestinal tract, skin, and gills. However, little is known about the microbial community of marine fish and their response to environmental stressors. The Deepwater Horizon disaster was the second largest oil spill in history, and had catastrophic effects on several commercially and ecologically important fish species in the Gulf of Mexico. This study aims to determine if exposure to oil will affect gut and and gill-associated microbiomes similarly in different species. We will accomplish this by sequencing the microbiomes of three pelagic species (Red Drum, Atlantic Croaker, and Red Snapper) exposed to oil along with a control group. This will allow us to gain insight on the core microbiomes of these species, compare the differences between pelagic and benthic species, and determine how microbial communities respond after exposure to oil.

**RP121 The effect of the plasticizer (Di-2-(ethylhexyl) phthalate) on microbiome-gut axis in zebrafish**

*O. Adamovsky, Masaryk University / Department of Physiological Sciences; A. Buerger, J.H. Bisesi, University of Florida / Environmental and Global Health; C.J. Martyniuk, University of Florida / Physiological Sciences*

Di-2-(ethylhexyl) phthalate (DEHP) is a plastic softener (plasticizer), that is currently used in products such as PVC, sealants, adhesives, paints, lacquers, printing inks and ceramics. DEHP is found in relatively high concentration in indoor air, surface waters, sediments, and perhaps most alarmingly, in municipal drinking water. DEHP is an emerging environmental contaminant of concern for human health due to ubiquitous and widespread use and for their potential to disrupt metabolic processes. Recent studies suggest that microbiome and gut play significant role in metabolism and disruption of microbiome-gut axis leads to effects on intake of nutrient, hormone balance, immunity and nervous system. The goal of this study is to determine whether DEHP, a model metabolic disruptor, adversely affect the zebrafish (*Danio rerio*) microbiome-gut axis and describe how taxonomical change in microbiome are reflected in gut. To stimulate chronic exposure of DEHP, we exposed the fish to 3 ppm DEHP via food for 30 and 60 days. Fish were fed once a day with commercial food mixed with DEHP. Fish were dissected and the content of gut and the gut tissue were collected. The composite and diversity of microbiome were studied by analyzing of 16s RNA genes using Illumina MiSeq. Sequence data were then separated into operational taxonomic units (OTUs) and annotated via mapping to a bacterial genome. OTU table was then used to link the phylogeny and the function of the microbiome using a bioinformatics approach PICRUSt. To identify genomic responses of DEHP in gut, we used microarray and real-time RT-PCR analysis followed by differential gene expression analysis. The data were then mapped to changes in cell processes and signaling pathways using Pathway Studio. This study revealed, that DEHP can significantly effects the composition of microbiome and its related function, and that these microbial changes together with the direct effect on gut has an effect on gut's transcriptome. Interestingly, the changes on gut and microbome are different for both sexes. The aim of this presentation is to present the microbiome-gut axis as a target for metabolic disruptors, such as DEHP and emphasize the need of multi-omics approach to study the phenomenon.

## Non-Conventional Exposure Routes and Transport Media of Consumer Product Chemicals to Improve Environmental Policy

**RP122 Leaching of Melamine from Resin Cups at Different Temperatures**

*M. Takazawa, New York State Dept. of Health; Y. Shimode, S. Suzuki, Bio Sciences and Bio Technologies / Chubu University; K. Kannan, Wadsworth Center / New York State Department of Health*

Melamine-based resins are used in many dishware because of durability, heat resistance and strength. Nevertheless, studies have shown that melamine exposure cause health risks in humans and pet animals. In this study, we evaluated leaching of melamine from dishes under normal cooking conditions. Prior to that a method was developed to extract melamine from water. Graphite carbon column, with π-π interaction sites, was able to extract melamine from water efficiently. Then we leached melamine from 3 types of dishes. The cups were added with 100 mL of water (20?) or hot water (90-100?) and sonicated for 10 min, and extracted by SPE-cartridge. In 20 ? water, melamine concentrations leached into water were in the range of < LOQ (0.04 ng/cm$^2$) to 0.55 ng/cm$^2$ for the three cups. In hot water, melamine leached at 0.37 to 1.25 ng/cm$^2$. Low-priced cups leached higher amounts of melamine than high-priced ones. Older-cups leached higher amounts of melamine than new-ones. These results suggest that melamine based dishware are source of human exposure to these chemicals.

**RP123 Non-Target HRMS for Tracking Sources of Human Contamination to Stormwater Conveyances**

*B. Du, Southern California Coastal Water Research Project / Chemistry; K. Peter, University of Washington, Tacoma / Center for Urban Waters; J. Steele, Southern California Coastal Water Research Project / Microbiology; J. Griffith, SCCWRP; E.P. Kolodziej, University of Washington, Tacoma/Seattle / Center for Urban Waters Interdisciplinary Arts and Sciences Civil and Environmental Engineering; K.A. Maruya, SCCWRP*

Fecal contamination presents a risk to human health, however, our incomplete understanding of the sources and relative contributions of fecal contamination and human-specific pathogens in stormwater runoff currently limits the scope and effectiveness of remedial activities. To complement biological measurements, we have developed an assessment tool using high-resolution mass spectrometry (HRMS) to identify significant sources and their relative contributions to effectively manage fecal contamination in stormwater conveyances from Southern California watersheds. This technique has been previously applied to track contaminant flows by comparing chemical fingerprints in urban receiving waters around Puget Sound (WA, USA). Here we demonstrated the utility of HRMS in source tracking of human fecal contamination by chemical fingerprinting of wastewater from different sources (e.g. POTWs, septics, and other non-point sources) and in receiving waterways to distinguish source-specific contributions. Water samples collected from select sanitary sewers and receiving waters were processed by solid phase extraction (SPE) without pre-filtration and analyzed by LC-QTOF-MS in electrospray ionization mode (ESI+). The HRMS data was blank subtracted, qualitatively compared, and statistically analyzed (e.g. hierarchical clustering analysis and fold change) to develop source-specific fingerprints. These fingerprints can then be manipulated, e.g. via characteristic sample dilution, to estimate source contributions in complex samples.

## Aquatic Toxicology, Ecology and Stress Response – Part 2

**RP124 "From single chemicals to complex mixtures" effect of contaminants of emerging concern on fish across three life stages**

*U. Hasbay, C.K. King, St. Cloud State University / Aquatic Toxicology Laboratory; E.G. Solarz, St. Cloud State University; H.L. Schoenfuss, St. Cloud State University / Aquatic Toxicology Laboratory*

Contaminants of emerging concern (CEC), including pharmaceuticals, personal care products and industrial agents may impact aquatic life. Previous studies have documented reduced escape performance in fathead minnow larvae exposed to diverse CECs. However, these studies did not consider the complex mixtures of CEC present in the environment. The current study tested the hypothesis that CECs in mixture change fathead minnow development and behavior differently than the mixtures' individual constituent. We assessed the potential of 20 commonly detected CECs to alter both juvenile (escape performance, feeding efficiency) and adult (nest defense, courtship, boldness) behaviors central to survival and reproduction after 96-hour flow-through exposures. We also assessed fathead minnow embryos that are exposed to the same CECs to determine exposure-associated developmental deficiency. In addition, we began the process of building increasingly complex mixtures of CEC using the same compounds. Compound concentrations and mixture composition were based on an analysis of nearly 500 water samples collected as part of the Great Lakes Restoration Initiative. Results to date suggest changes in survival, escape performance and feeding efficiency along with spinal curvature. The survival was significantly reduced ($p< 0.05$, ANOVA) in larvae exposed to estrone, desvenlafaxine, and tris(2-butoxyethyl) phosphate. In both metolachlor and DEET exposures, the medium concentration (environmental concentration) had significantly more non-responsive larvae as part of the escape performance assay as was the case in the highest concentration (10x) of atrazine exposure. Interestingly, several treatments increased the feeding efficiency of larvae under chemical stress. Assessing embryonic, larval, and adult life stages of fathead minnows, exposed to the same CECs, will aid in identifying the most sensitive stage at the molecular, organismal, and apical level of biological organization. We expect that these evaluations will lead us to understand the effect of CECs in mixture on fish survival, development and behavior.

**RP125 Acute microcystin-LR exposure affects the complement C9 synthesis by the interference of thyroid hormones in adult zebrafish (*Danio rerio*)**

*Y. Gao, Yunnan Agricultural University; Z. Liu, D. Li, Huazhong Agricultural University / College of Fisheries*

The persistence of microcystin-LR (MC-LR) in aquatic environments raises potential disturbances in the thyroid hormone (TH) homeostasis, which results in the downstream biological processes associated with TH interference. However, it has been not clarified how MC-LR affect certain downstream biological processes by TH disturbances. In this study, 12 genes were down-regulated in MC-LR treatment zebrafish with at least two-fold change, compared with the control fish through integrative bioinformatics analysis from Gene Expression Omnibus (GEO) datasets GSE12214 and GSE73739. Through Protein-protein Interaction (PPI) analysis between candidates and thyroid genes at the protein level, complement component 9 (C9) was highlighted as one of the most probable molecules among the 19 candidates after exposure to MC-LR. After exposure to 50, 100, 200 and 400 μg/L MC-LR for 24, 48, 72 and 96 hours, some interference effects were observed on the thyroid hormone metabolism of adult zebrafish at thyroxine (T4) and triiodothyronine (T3) levels, iodothyronine deiodinase (Dio) activities and related-genes expression (*crh*, *tsh*, *ttr*, *nis*, *tpo*, *dio*, *thra* and *thrb*) pattern. Acute MC-LR exposure stimulated negative feedback regulation of hypothalamic-pituitary-thyroid (HPT) axis in adult zebrafish with females exhibiting more sensitivity than males. In conclusion, the toxicity of MC-LR may affect the complement system involved in innate immunity through the activated thyroid hormone receptors (TRs) by TH binding to the C9 promotor, regulating membrane attack complex (MAC) function in zebrafish.

**RP126 Analysis of Multiple Cetacean Reproductive and Stress Steroid Hormones in 50 mg Blubber Sample by Liquid Chromatography – Tandem Mass Spectrometry**

*M. Hayden, Texas Tech University / The Institute of Environmental and Human Health; D. Klein, S. Subbiah, Texas Tech University / Department of Environmental Toxicology; V. Lesage, Y. Morin, Fisheries and Oceans Canada / Maurice Lamontagne Institute; J. Urbán-Ramírez, Universidad Autónoma de Baja California Sur / Departamento de Biología Marina; C. Lopez Montalvo, Universidad Autónoma de Baja California Sur; S. San Francisco, M. Zabet-Moghaddam, R. Bhawal, Texas Tech University / Center for BioTechnology Genomics; C.A. Godard, Texas Tech University / Environmental Toxicology / The Institute of Environmental and Human Health*

Steroid hormone profiling in cetaceans provides important information for conservation and management. This is critical for endangered species. Until 2017 cetacean blubber hormone analyses were only conducted using immunoassays. This methodology is rarely compatible with multiple analyses in biopsy samples due to mass requirement, and the majority of published immunoassay studies reported using 75-150 mg of blubber per hormone analysis. We report here on a Liquid Chromatography-Tandem Mass Spectrometry (LC-MS/MS) method for the simultaneous quantitation of reproductive and stress steroid hormones in as little as a 50 mg blubber sample. Blubber samples collected by skin biopsy or necropsy and ranging from 50 – 150 mg wet weight (w/w) were extracted for steroid hormone analysis in two cetacean species (beluga *Delphinapterus leucas* and bowhead whale *Balaena mysticetus*). Gel permeation chromatography was employed for lipid removal. Steroid hormones were quantified using a Thermo Scientific TSQ Quantum Access Max MS mass spectrometry system in heated electrospray positive and atmospheric-pressure chemical negative ionization modes through selected reaction monitoring. Isotopically-labeled internal standards were used for endogenous steroids quantitation. Method detection and quantitation limits were compatible with steroid hormone levels reported in cetacean blubber. Method extraction efficiencies were comparable to liquid-liquid extraction. Progesterone, testosterone, cortisol, and estradiol were successfully quantitated from 50 mg w/w cetacean blubber using LC-MS/MS. To our knowledge, this is the first report on pregnancy detection and blubber estrogen analysis by LC-MS/MS. Due to its low mass requirement, this significant advancement in blubber steroids determination makes this method invaluable as it can be accomplished concurrently with other research investigations relying on a single biopsy sample.

**RP127 Antennae Regeneration of the Marine Amphipod *Parhyale Hawaiensis***

*O. Diehl, P. Assano, School of Technology / UNICAMP / LAEG; G.D. Umbuzeiro, School of Technology / UNICAMP / LEAL*

*Parhyale hawaiensis* is a marine amphipod of worldwide circumtropical distribution and has been used in acute ecotoxicological tests. *P. hawaiensis* is able to regenerate its appendages, limbs and tissues after an injury or lost during the entire course of their life. Regeneration can be used as an ecotoxicological endpoint to assess potential teratogenic compounds and their impact on stem cells.. Thus, the aim of this study was to obtain data on regeneration of antennae of *P. hawaiensis* to determine the regeneration time of fifty per cent of population. On day one left antennae of six months old organisms were amputed with sterilized tweezers, each organism transferred to recipients containing 100 mL salt water. Each test consisted of 20 organisms, 10 males and 10 females. During this period, organisms were feed three times a week, the necessary conditions of salinity, temperature, aeration, substrate and luminosity were provided. Four independent experiments were performed. The organisms were monitored daily until all of them undertook full regeneration. Antennae regeneration occured from 7 to 20 days (n=80) after amputation. Males and females behaved statistically differently, although the difference was not biologically relevant ($T_{50\%}$=14 days for males, $T_{50\%}$=12 days for females and $T_{50\%}$=13 days for both). The regeneration time of fifty per cent of the population seems to be viable endpoint. as an ecotoxicological test.To allow testing of toxicants with low Kow and water solubity usually DMSO is used as solvent. To verify its non effect concentration, organisms (n=20 per treatment) with amputed antennae were exposed individually in plastic vials containing different concentrations of DMSO dissolved in 100 mL salt water under the same conditions described above, DMSO can be used as a solvent for toxicants at a maximum concentration of 0.2%. Next steps will be the exposure of organisms to selected toxicants, as growth inhibitor, to verify their ability of affecting the regeneration process in the developed experimental conditions. *Acknowledgement:* Conselho Nacional de Desenvolvimento Científico e Tecnológico" (CNPq-PVE Process: 400362/2014-7) for funding and PIBIC for undergrad fellowship. Amanda dos Santos e Gabriel Rampazzo Magalhães for technical contribution.

**RP128 Atlantic Cod (*Gadus morhua*) Shrinks in Response to Environmental Pollutants Exposure**

*M. Iida, Kyushu Institute of Technology / Department of Bioscience and Bioinformatics; K. Takemoto, Kyushu Institute of Technology*

As do global warming and overfishing, environmental pollutants (e.g., polychlorinated biphenyls (PCBs), pesticides and metals) impact marine ecosystems; in particular, its exposures could pose significant risks to fish growth. However, how fishes respond to the exposure of pollutants is poorly understood. Thus, we estimated the effects of environmental pollutants exposures on the lengths (sizes) of Atlantic cod (*Gadus morhua*), using a time series of more than 4,000 individual cod lengths and environmental contaminants levels of cod liver observed in a variety of marginal seas of the Atlantic Ocean (Baltic Sea, Greater North Sea, Norwegian Sea, Barents Sea, and Icelandic Water) in the 1990s and the 2010s. Using linear mixed-effects models, we accounted for spatial population structure and the nested structure of the observation data. Similar to previous studies, the cod sizes increased with the advance of age, and they decreased by the amount of annual landing. Oceanographic parameters also significantly influenced the cod sizes. The sizes were positively associated with salinity and nitrate concentration; however, they were decreased along with increasing dissolved oxygen, phosphate, silicate concentration, and temperature. More importantly, we found a positive correlation between the cod sizes and hexachlorobenzene (HCB) levels; on the other hand, the sizes were negatively affected by cadmium (Cd), lead (Pb), total hexachlorocyclohexane (HCH) and total PCBs levels. These results suggest that environmental contaminants cause cod shrinking, along with ocean warming and overfishing in the Atlantic Ocean.

**RP129 Bivalve responses to graphene oxide exposures**

*B. Khan, National Research Council of the National Academies / USEPA / Atlantic Ecology Division; A.S. Adeleye, University of California, Irvine / Civil & Environmental Engineering; R.M. Burgess, USEPA / Atlantic Ecology Division; R. Smolowitz, Roger Williams University; S.M. Russo, Oak Ridge Associated Universities / USEPA, Narragansett; K.T. Ho, USEPA / Atlantic Ecology Division*

Graphene is a two-dimensional nanomaterial composed of $sp^2$ hybridized carbon atoms. Due to its unique mechanical, thermal, electrical, and optical properties, the use of graphene family nanomaterials (GFNs) in electronics, biomedicine, surface coatings, filtration devices, and composite materials is rapidly growing. It is inevitable that with widespread use, GFNs will make their way to aquatic ecosystems. However, current information on fate and toxicity of GFNs, such as graphene oxide (GO), and their environmental impacts is scarce. Filter-feeding bivalves, such as *Crassostrea virginica* (Eastern oysters), are good models to study the effects of GO exposures on aquatic organisms. The goal of this pilot study is to evaluate effects of in vivo GO exposures on oysters using a static renewal design. Each oyster was placed in a beaker with 1 L of 0.22 µm filtered natural seawater that contained 0, 1, or 10 mg/L GO. Oysters were fed a mixed algal diet and three renewals were performed daily. For every renewal, a GO suspension was prepared in seawater and sonicated before its addition to the beakers. Water samples were analyzed for GO concentration and effective diameter after each renewal. After 72 hours of exposure, oysters were placed in clean seawater for 3 hours prior to harvesting gill and digestive gland tissues. Tissues were analyzed for lipid peroxidation, a marker of oxidative damage, and for activity of glutathione-s-transferase (GST), a detoxification enzyme that also participates in oxidative stress and cell signaling pathways. Additionally, gill tissues were fixed for histopathological analyses. Elevated lipid peroxidation in GO exposed oysters was found. No significant changes in GST activity were observed, but reduced total protein levels were noted in exposed oysters. Loss of mucous cells, hemocytic infiltration, and vacuolation were also observed in gill tissues. Results indicate that short-term GO exposures can induce oxidative stress, gill epithelial inflammation, and adversely affect overall health in oysters. Evaluation of sublethal effects of exposures to an emerging contaminant, such as GO, is critical to understanding the risks associated with increasing commercial usage of nanomaterials. Current long-term analyses of exposure effects are aimed at identification of molecular initiating events and subsequent key events that can contribute to the development of adverse outcome pathways (AOPs) for nanomaterials.

**RP130 Chinese medaka (*Oryzias sinensis*): A fish model linking laboratory and field effects in aquatic toxicology studies in China**

*Z. Zhang, Peking University*

The unprecedented deterioration of the aquatic environments has been occurred in China during the past decades. Ecosystem degradation can be seen in many rivers, and even worse in some rivers where it is difficult to find the presence of fish. So, toxicity investigations of contaminants in aquatic environments on fishes are of great concern. But there is often embarrassment when linking the effects found in traditional model fishes in the laboratory and the phenomena observed in wild fishes in the field due to species differences. Field caging experiments are sometimes effective, however, experimental animals and their eggs or offspring would accidentally be released into the environment and cause alien invasion. So developing a new fish model from native species for laboratory study should be preferred. Here we select Chinese medaka (Oryzias sinensis), a close relative species of Japanese medaka (Oryzias latipes), and established a laboratory brood stock of Chinese medaka. Using next generation sequencing (NGS) technologies and modern bioinformatics tools, we got the genome and transcriptome of Chinese medaka. And finally, the fish model was successfully used to analyze and identify the key hazards to fish populations in some rivers based on experiments at molecular, cellular and individual levels.

**RP131 Comparative toxicity of a nano-TiO2, a bulk TiO2, and a food additive TiO2 to *C. elegans* – Does the size matter?**

*H. Ma, University of Wisconsin, Milwaukee / Zilber School of Public Health; K.A. Lenz, UWM-ZSPH / Environmental Health Sciences; C.Y. Yuan, Case Western Reserve University; L. Wallis, Western Washington University / Institute of Environmental Toxicology*

Bulk-sized $TiO_2$ has been used as food additives for years and is considered safe for human and ecosystem health because of its inertness. Recent studies found that food additive $TiO_2$ contains significant portion of nano-sized (i.e., < 100 nm) $TiO_2$ which may pose unforeseen health risks for humans. Here we investigated toxicity effects of a commercial food additive $TiO_2$ as compared to nano-sized $TiO_2$ (P25) and bulk $TiO_2$ to a model organism the nematode *C. elegans*. Particle size characterization was performed using scanning electron microscopy (SEM) and X-ray diffraction (XRD). Photoreactivity (generation of reactive oxygen species) of the materials were determined using a fluorescence-based assay as well as methylene blue degradation. Toxicity endpoints included acute phototoxicity (lethality), reproduction, and lifespan. Uptake of $TiO_2$ particles was assessed by microscopy imaging followed by hyperspectral imaging. We found that approximately 20% of the food additive $TiO_2$ had particle size below 100 nm. Overall, food additive $TiO_2$ had similar size distribution to bulk $TiO_2$, with average primary particle size of 148 nm (range: 53, 308) and 129 nm (64, 259), respectively. Under environmentally relevant UV radiation, P25 showed significantly higher photoreactivity and phototoxicity than food additive $TiO_2$ and bulk $TiO_2$, with a 24-h LC50 of 8.7 mg/L (95% CI: 8.5, 8.9). All three materials induced concentration-dependent impact on worm reproduction at concentrations up to 10 mg/L, and P25 showed a greater impact at an identical concentration. All three materials impacted worm lifespan and P25 showed the greatest effect, shortening lifespan by 2 days. In addition, worms exposed to all three materials showed age-associated vulval integrity defects during aging, with a frequency of 30~50% as compared to less than 15% in control worms. Uptake of $TiO_2$ into worm intestinal system was obvious for all three $TiO_2$ materials; however, uptake into other organs was most significant for P25, followed by food additive $TiO_2$, and no significant uptake of bulk $TiO_2$ was observed. Comparable toxicity effects between food additive $TiO_2$ and bulk $TiO_2$ correspond well with their similar primary particle size and size distribution, suggesting that particle size is a determining factor for toxicity in this case. Future studies should focus on the uptake of $TiO_2$ particles into different organs of the worm and the associated biological effects from molecular and cellular levels.

**RP132 Comparative Transcriptomic Response of a Model Fish and Amphibian to Trifloxystrobin Early Life Stage Exposures**

*C. Lavelle, C.R. Lilavois, P. Harris, N. Zielinski, USEPA / GED; M. Hamilton, H. Skowronski, USEPA; S. Raimondo, J. Awkerman, USEPA / Gulf Ecology Division*

Size at metamorphosis and time to metamorphosis indicate developmental effects in amphibians that could result in population-level impacts. Current risk assessment practice uses early life stage fish data when data for larval amphibians are not available. While fish are sufficiently sensitive to a range of chemicals, developmental delays could have relatively greater impacts on subsequent amphibian life stages. As pesticide exposure has been suggested to contribute to amphibian declines, it is important to understand the uncertainties around using this form of surrogacy in risk assessments aimed at protecting amphibian populations. Strobilurin fungicides are an economically important class of pesticides designed to inhibit the mitochondrial respiratory chain ultimately interfering with ATP production. Trifloxystrobin (TX), a heavily used strobilurin, is frequently detected in aquatic systems, often at levels known to cause sub-lethal toxicity in a range of species. In this study we conducted 10-day early life stage exposures of zebrafish, *Danio rerio*, and African clawed-frog, *Xenopus laevis*, to TX to determine if growth, development, and gene expression changes were similarly altered. Log-logistic 96-hr LC50 curves for *D. rerio* and *X. laevis* show that *X. laevis* is more sensitive to TX exposure than *D. rerio* with LC50 values of 45.85 ± 3.98 µg/L and 135.86 ± 7.58 µg/L, respectively. The LC50 for the entire 10-day exposure period was more similar between *D. rerio* and *X. laevis* at 79.13 ± 4.61 µg/L and 45.61 ± 3.83 µg/L, respectively. While a delay in hatching and pigmentation was observed in *D. rerio,* no effects on length or weight were observed. However, a dose-dependent decrease in weight and developmental delay were observed in *X. laevis* as fewer TX-exposed tadpoles reached NF stage 50 by the experiment termination than control tadpoles. Tissues collected from exposed individuals were used to compare differential gene expression on targets related to endocrine signaling, oxidative stress, mitochondrial function, growth, and apoptosis. Species-specific gene expression patterns suggest that different biological pathways in *D. rerio* and *X. laevis* are perturbed by TX exposure. Future studies will examine the potential of the observed changes in gene expression to be predictive of more population-relevant endpoints, such as time to metamorphosis.

**RP133 Comparing apical responses and molecular toxicity pathways in two amphibian species following chronic exposure to ethinyl estradiol and chlorpyrifos**

*N. Baldwin, University of Saskatchewan / Toxicology Centre; M. Brinkmann, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre; A.J. Masse, Toxicology Centre; D. Crump, Environment and Climate Change Canada / National Wildlife Research Centre; N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre; N.S. Hogan, University of Saskatchewan / Department of Animal and Poultry Science and Toxicology Centre*

Environmental contaminants have been listed as the second most important threat to amphibians after habitat loss. Exposure to contaminants can have adverse outcomes on amphibian health, such as altered rate of metamorphosis, reproductive effects, immune suppression, and behavioural effects. However, little is known regarding the sensitivity of native amphibian species and even less regarding the specific mechanisms of action and the associated toxicity pathways that drive apical responses to contaminants. Therefore, the main goal of this study is to identify, validate and compare key molecular toxicity pathways that are predictive of contaminant-induced apical responses in the native North American anuran amphibian species, *Lithobates sylvaticus* (wood frog) and the laboratory model species, *Xenopus laevis*. Specifically, this study focused on chlorpyrifos (CPY) and ethinyl estradiol (EE2), two anthropogenic contaminants of concern with different modes of action and characterised apical effects in amphibians. Post-hatch individuals were exposed for 96 h to CPY (0.5, 2, 8 ug/L) and EE2 (0.04, 0.2, 1 ug/L) and sampled for whole transcriptome, whole proteome and targeted metabolome analyses to characterize molecular toxicity pathways following early life stage exposure. A subset of tadpoles was then transferred to a flow-through diluter system for exposure to metamorphosis (~ 40 d) and assessed for developmental stage, morphometrics, organ histopathology and genetic sex. The ultimate goal of this study is to identify critical toxicity pathways for early life stages that enable prediction of key genes to be used in an early life-stage gene expression assay to predict apical outcomes of ecological and regulatory relevance in amphibians. This study is part of the EcoToxChip project (@ecotoxchip).

**RP134 Comparisons of the effects of nanoparticles on the activity and biosynthesis processes of β-galactosidase using a mutant strain *E. coli***

*I. Kong, X. Yang, W. Wi, M. Kim, Yeungnam University / Environmental Engineering*

The effects of nanoparticles (NPs) on the activity and biosynthesis of enzyme (β-galactosidase) were compared in the presence of six metal oxide NPs using mutant strain *E. coli*. Various effects were observed according to the types of NPs. In general, the effects on enzyme activity were greater than on that of biosynthesis, except with $Al_2O_3$ NP. Statistically significant differences were observed between these two biological activity (<em>p </em 0.05). For both cases, ZnO and CuO NPs caused the considerably high inhibition among tested NPs. The ECsub50s/sub for ZnO were 0.19 and 3.68 mg/L on the enzyme activity and biosynthesis, respectively. Slightly different orders of ECsub50s/sub were observed as followings: ZnO > CuO > NiO > $Co_3O_4$ > $TiO_2$, $Al_2O_3$ on enzyme activity and ZnO > CuO >NiO, $Al_2O_3$ > $TiO_2$, $Co_3O_4$ on the biosynthesis process. The causes of this different phenomenon are unclear at this point. More research will be needed to be confirmed with further in-depth studies, such as molecular level investigations, to elucidate the different mechanism of the toxicity.

**RP135 *Daphnia magna* assay application to toxicity of nickel compounds**

*T. Abe, National Institute of Technology / Tsuruoka College / Creative Engineering; R. Obara, National Institute of Technology / Tsuruoka College; S. Ito, National Institute of Technology, Tsuruoka College / Technical Support Center*

Various inorganic chemicals exist in environment, their come from not only natural source but also artificial source. Inorganic chemicals include metal, metal ion, metal salts, and nano materials. We expect that the metal salts also affect organisms. The following studies mainly use metal salts as inorganic chemicals. Median effective concentrations ($EC_{50}$s) were used from previous studies and several literatures. *Daphnia magna* immobilization test is listed in OECD Guidelines for the Testing of Chemicals (TG202). Culture medium was used Elendt M4. Acute $EC_{50}$s of nickel salts employed values of chloride, nitrate, sulfate, and acetate. Following listed compounds, nickel chloride ($NiCl_2$: $NiCl_2$?$6H_2O$, CAS No. 7791-20-0), nickel nitrate ($Ni(NO_3)_2$: $Ni(NO_3)_2$?$6H_2O$, CAS No. 13478-00-7), nickel sulfate ($NiSO_4$: $NiSO_4$?$6H_2O$, CAS No. 10101-97-0), and nickel acetate ($Ni(CH_3COO)_2$: $Ni(CH_3COO)_2$?$4H_2O$, CAS No. 6018-89-9) were used. Copper sulfate ($CuSO_4$: $CuSO_4$?$5H_2O$ CAS No. 7758-99-8) was used for positive control. Result of acute assay, 48h – $EC_{50s}$ (nominal nickel compound concentration) were 21.6 mg / L ($NiCl_2$?$6H_2O$), 23.5 mg / L ($Ni(NO_3)_2$?$6H_2O$), 5.35 mg / L ($NiSO_4$?$6H_2O$), 11.6 mg / L ($Ni(CH_3COO)_2$?$4H_2O$) respectively. Result of acute assay, 48h – $EC_{50s}$ (nominal nickel ion concentration) were 5.33 mg / L ($NiCl_2$: $Ni^{2+}$), 4.74 mg / L ($Ni(NO_3)_2$: $Ni^{2+}$), 1.19 mg / L ($NiSO_4$: $Ni^{2+}$), 2.74 mg / L ($Ni(CH_3COO)_2$: $Ni^{2+}$) respectively. Result of acute assay, 48h – $EC_{50s}$ (measured nickel ion concentration by ICP-AES) were 0.52 mg / L ($NiCl_2$: $Ni^{2+}$), 0.23 mg / L ($Ni(NO_3)_2$: $Ni^{2+}$), 0.91 mg / L ($NiSO_4$: $Ni^{2+}$), 2.38 mg / L ($Ni(CH_3COO)_2$: $Ni^{2+}$) respectively. These $EC_{50}$s were almost same as previous studies and several literatures. Nickel compounds should be careful each salts, considering measured nickel concentration (e.g. max. 1.6 mg $Ni^2$ / L, 2001 in Japan) from environment water.

**RP136 Developmental hepatotoxicity of PCB-11 in combination with PCB-126 in zebrafish (*Danio rerio*) is dependent upon the window of exposure**

*M. Roy, A.R. Timme-Laragy, University of Massachusetts Amherst / Environmental Health Sciences*

3,3'-Dichlorobiphenyl (PCB-11) is a non-legacy, lower-chlorinated PCB congener that is an unintended byproduct of diarylide pigment manufacturing and is widely detected in environmental samples. Our previous research in zebrafish (*Danio rerio*) embryos demonstrates that static exposures to PCB-11 alone does not cause toxicity, but in co-exposures starting at 24 hours post fertilization (hpf) with the potent aryl hydrocarbon receptor (Ahr) agonist 3,3',4,4',5-Pentachlorobiphenyl (PCB-126), PCB-11 acts as an Ahr antagonist to rescue the cardiovascular and craniofacial malformations induced by PCB-126. PCB-126 also induces a stunted liver size when exposures begin at 24 hpf. We hypothesized that PCB-11 would rescue this liver phenotype, and to test this, used transgenic *Tg(gut:GFP)* zebrafish to visualize liver development in vivo. Embryo exposures were initiated at different critical windows of liver development: 24 hpf (pharyngula stage, before liver budding), 48 hpf (hatching stage, before liver growth initiation), or 72 hpf (larval stage, during liver extension). Exposure conditions were comprised of static concentrations of either 0.05% DMSO, 20 µM PCB-11, 5 nM PCB-126, or a combination of 20 µM PCB-11 + 5 nM PCB-126. At 96 hpf, a time point when zebrafish livers are extending ventrally, embryos were assessed for gross embryo morphology and liver area. Our results showed that over all critical exposure windows 20 µM PCB-11 alone did not affect gross morphology or liver size of fish. Exposures to PCB-126 starting at 24 hpf were consistent with previous studies, with fish exhibiting severe morphological deformities and a 50% reduction in liver size. Exposures to PCB-126 starting at 48 hpf induced some morphological deformities, but PCB-126 exposures starting at 72 hpf produced normal fish; liver size in fish exposed to PCB-126 starting at 48 hpf and 72 hpf developed normally. In co-exposures starting at 24 hpf, 20 µM PCB-11 rescued stunted liver size and other associated morphological deformities induced by PCB-126. In co-exposures starting at 48 hpf and 72 hpf, fish exposed to 20 µM PCB-11 + 5 nM PCB-126 did not induce gross morphological deformities, however, this co-exposure significantly reduced liver size by 31% and 24%, respectively. This study highlights the importance of examining emerging contaminants in a mixtures context, as well as the usefulness of transgenic zebrafish lines to examine organ-level effects of these mixtures.

**RP137 Difference in zinc tolerance of freshwater snails from contaminated and uncontaminated sites**

*J. Hickey, J.B. Belden, S.T. McMurry, Oklahoma State University / Integrative Biology*

The Tri-State Mining District (TSMD) is a historic mining area located in northeast Oklahoma, southwest Missouri, and southeast Kansas and was an important source of lead and zinc to the United States from the 1850s to the 1970s. These mining operations have resulted in elevated levels of lead, zinc, and cadmium in nearby terrestrial and aquatic environments. The consequences of this contamination include the designation of Tar Creek as an EPA Superfund site in 1983. The present study tested the hypothesis that freshwater snails (*Physa acuta*) found in metal-contaminated waters in the Oklahoma portion of the TSMD will be more tolerant to zinc than those found in less-contaminated waters. Laboratory cultures were developed by obtaining snails from 10 sites across a range of metals contamination within the same watershed. Sublethal zinc toxicity tests (21d) were conducted measuring growth and egg production in response to varying levels of zinc exposure. Preliminary results indicate that snails originally collected in uncontaminated sites are more sensitive to zinc exposure for both growth, reproductive, and mortality endpoints as compared to snails originally obtained from more contaminated sites.

**RP138 Differences between the impacts of acute and sub-chronic NPs exposures on *Gammarus fossarum***

*K. Mehenaoui, University of Lorraine / Laboratoire Interdisciplinaire des Environnements Continentaux; S. Cambier, T. Serchi, Luxembourg Institute of Science and Technology / Environmental Research and Innovation Department; N. Valle, Luxembourg Institute of Science and Technology / Material Research and Technology Department; F. Guérold, University of Lorraine / Laboratoire Interdisciplinaire des Environnements Continentaux; L. Giamberini, Université de Lorraine / LIEC / CNRS; A. Gutleb, Luxembourg Institute of Science and Technology / Environmental Research and Innovation*

Silver (AgNPs) and gold nanoparticles (AuNPs) have really specific and unique properties that bring a high interest for their use in different scientific and industrial applications. This increase of their use will ultimately result in their release in aquatic ecosystems and consequently represent a hazard to aquatic organisms. Among those aquatic organisms amphipods are widespread and important component of the aquatic macroinvertebrate assemblage and will certainly be exposed to AgNPs and AuNPs. For these reasons, *Gammarus fossarum* was selected as model organism for this study. The aim of the present work was to evaluate the acute (72h, without food) and the sub-chronic (15d with food) toxicity of AgNPs and AuNPs on *G. fossarum*. In both exposure scenarios, we used $AgNO_3$ as a positive control and as a reference in order to address the contribution the potentially released ions from the AgNPs on the observed effects. The present work evaluated the influence of the surface coating (citrate CIT, polyethylene glycol PEG) on effects induced by the NPs regarding the type of exposure. The uptake of AgNPs and AuNPs by *G. fossarum*, their tissue distribution and the modulation of the expression of stress related genes were investigated in both acute and sub-chronic exposure scenarios. A significant uptake of Ag and Au was observed in exposed animals, with a significant effect of the coating with CIT-NPs showing higher bioaccumulation than PEG-NPs. The analysis of the tissue distribution of the different NPs revealed the presence of the AgNPs in the cuticle and the gills and AuNPs in the gut area in the case of the acute exposure and this profile was kept after the sub-chronic exposure. However, between the acute and sub-chronic exposure conditions two different gene expression profiles were obtained. For instance, for AgNPs, in the acute exposure condition, the *CuZnSOD* expression was impacted without any impact on the expression of *NaKATPase* whereas in the sub-chronic exposure condition a clear impact was visible on the expression of *NaKATPase* whereas no significant alteration was detected on the *CuZnSOD* expression.

**RP139 Do land use patterns along Central Oregon rivers impact fish reproductive health and development?**

*A. Brande, Oregon State University / Integrative Biology; D. Heil, Oregon State University, Cascades / Integrative Biology; A. Petersen, Oregon State University, Cascades*

Central Oregon is home to some of the fastest growing cities in the United States. Industry, agriculture, and tourism are rapidly increasing. The water quality and ecosystem health of the Deschutes River and its tributary, the Crooked River, are being impacted by increased anthropogenic contamination. *Gasterosterus aculeatus*, the Threespine Stickleback, is a widely used laboratory model for measuring the effects of water quality on vertebrate health. A naturally occurring stickleback population in Central Oregon rivers provides an exciting opportunity to harness the power of this lab model to test water quality issues in a natural setting. Do land uses associated with toxic and/or endocrine disrupting compounds- such as golf courses and urban storm water drainages – impact fish health in adjacent waterways? To address this question, we have measured concentration of the steroids 11-Ketotestosterone (11-KT) and 17β-Estradiol (E2), fish sex ratios, and gonad development in threespine stickleback from waterways adjacent to three main land uses: golf courses, urban centers, and protected watershed (control sites). Using standard pathohistology and endocrine ELISA methods, we have found that resident fish from waterways adjacent to golf courses have shown elevated levels of 11-KT. Interestingly, preliminary data show elevated vitellogenin production in males where 11-KT was also high, suggesting the presence of androgenic contaminant. We find increased spermatogenesis in male stickleback, and a decrease in oocyte production in females. Like humans, stickleback exhibit X Y sex determination systems. Preliminary sex genotype data have not identified any intersex individuals, but we are examining altered sex ratios in some populations from disturbed sites. Our initial findings suggest that patterns of disease and dysgenesis may emerge from our monitoring of sites along these rivers. These data provide preliminary support for using stickleback throughout Central Oregon as a “canary in the coal mine” for water quality. Next steps will include using yeast screens for estrogenicity and androgenicity on water collected from the Deschutes and Crooked River, and to examine the physiological and genetic mechanisms underlying the dysgenesis found in stickleback at some sites. We will discuss the broader implications of our findings in light of natural resource and urban growth management and mitigation of the effects of the rapid growth cities in Central Oregon.

**RP140 Does exposure to contaminants during early life stages impede recovery of the endangered copper redhorse?**

*H. Marchand, McGill University / Macdonald Campus / Natural Resource Sciences; B. Barst, McGill University / Dept of Natural Resource Sciences; E. Boulanger, McGill University / Natural Resource Sciences; M. Houde, Environment and Climate Change Canada / Aquatic Contaminants Research Division; N. Vachon, Ministère des Forêts, de la Faune et des Parcs; J. Head, McGill University / Natural Resource Sciences*

The copper redhorse (*Moxostoma hubbsi*) is an endangered fish that exists only in the St. Lawrence River and its main tributaries in southern Quebec, Canada. According to recent estimates, copper redhorse are restricted to a single population consisting of at most 2,000 mature individuals. A myriad of anthropogenic factors may be leading to the poor natural recruitment of copper redhorse, including contamination of the only known spawning grounds and nursery habitats within the Richelieu River. Previous research on the effects of contaminants on copper redhorses has focused on adult fish and on legacy contaminants. Here, we focus our efforts on the early life stage and emerging contaminants. Water samples were collected from two known spawning areas, in December 2017 (n=2 per site). The purpose of this initial screen was to determine which contaminants might be present and of concern. A series of pharmaceuticals and personal care products (PPCPs), flame retardants, and pesticides were measured in the surface water samples. Preliminary results indicate that even in December when pesticides were not applied to surrounding croplands, some herbicides, such as atrazine (0.036 µg/L) and glyphosate (0.023 µg/L) were present in river water, although they did not exceed Quebec’s criterion for protection of aquatic life as they do in the spring. The glyphosate metabolite, aminomethylphosphonic acid, was also present (0.053 µg/L). The contaminant with the highest concentration detected was metformin (0.517 µg/L), a diabetes drug. At high concentration (40 µg/L), metformin has been linked to intersex and reduced fecundity in fish. In spring 2018, we deployed passive samplers at both sites (n=2 per site) to capture the temporal variation of pesticides during the spawning season, but also to determine their bioavailability. We also measured atrazine and glyphosate in river water collected from two tributaries and the Richelieu River spawning grounds. Building on previous results, we will rear copper redhorse eggs obtained from the provincial government artificial breeding program during the summer. Half the eggs will be constantly exposed to river water while the other half will be exposed to laboratory water. A suite of biomarkers will be measured to evaluate effects of exposure. This study will provide valuable data on the types of contaminants present in the Richelieu River and increase our knowledge on the potential effects they have on an endangered fish.

**RP141 Does growth efficiency influence mercury bioaccumulation in Largemouth Bass from Missouri reservoirs?**

*K. Knott, R. O’Hearn, Missouri Department of Conservation / Environmental Health; D. Niswonger, Missouri Department of Conservation; L. Lawson, J. Wenzel, Missouri Department of Health and Senior Services; M. McKee, Missouri Department of Conservation*

The Missouri Department of Health and Senior Services recommends that women of child-bearing age and children under 13 consume no more than one meal per month of large predatory fish due to elevated mercury (Hg). However, Hg concentrations in fish of the same size and species can differ depending on the reservoirs from which they were taken. We currently lack an understanding of the key factors contributing to variable Hg bioaccumulation. This has led to confusion regarding the safe consumption of fish. Previous monitoring efforts by the Missouri Department of Conservation reported that Hg concentrations in Largemouth Bass (*Micropterus salmoides;* LMB) were positively correlated with fish length and negatively correlated with reservoir surface area. Elevated Hg concentrations may also relate to body condition of fish and habitat quality, but these interactions have yet to be examined for LMB in Missouri. Muscle Hg concentrations of LMB (n=12/lake category) from 6 small (12 inches, PSD12 57-68) featured LMB that were in relatively good condition (Mean ± SD, 111 ± 40) and had the lowest concentrations of Hg (236 + 168 ppb; p< 0.001). Hg concentrations were highest (445 ± 247 ppb) and $W_r$ lowest (96 ± 34) for LMB in lakes that had a PSD12 < 40 indicating a stunted population. LMB from lakes with proportionately greater number of large fish (PSD12>70) had Hg concentrations and $W_r$ at intermediate levels (267 ± 150 and 97 ± 14, respectively). A more balanced population suggests that prey abundance and water quality conditions are favorable, and that fish may be limiting Hg bioaccumulation through growth dilution. Greater bioaccumulation of Hg may result from relatively slower growth and greater metabolic demands of LMB in stunted populations. These data will assist in decisions as to whether site-specific fish consumption advisories due to Hg are warranted, and whether fisheries management strategies could mitigate Hg bioavailability. This information will aid in the protection of fish consumers, and preserve the economic and recreational value of Missouri’s aquatic resources.

**RP142 Effect of heavy metals as important environmental pollutants**

*K. Adegbenro, University of Lagos, Nigeria*

The pursuit of industrailization results in the pollution of the environment. Analyzing the toxicological effect of pollutant in the environment, pollutant include ; persistent organic pollutant (POP), heavy metals and nutrient. i am concern about heavy metals because of thier common occurence and public health relevance. the key heavy metals are Mecury (Hg), Cadmium (Cd), Arsenic (As), Chromium (Cr), Lead (Pb), others include Zinc, Copper and Nickel. heavy metals are biacummulative and enter the environment through mining activities, industrial discharge and household electronic appliance and e-waste. They pose risk to human and animal even at low concentration. lead (Pb) causes damage to nervousse system, kidney and reproductive system, Cadmium (Cd) causes renal disfunction and bone degeneration, while Nickel which is used mainly in electroplating and causes harm to aquatic systems. Mecury (Hg) can cause deformity in new-born babies and acquatic bodies. Chronium (Vi) also causes liver and kidney damage and skin Ulceration. I therfore summit that toxic effect and poisoning by heavy metals world wide require strict regulations for discharge of solid waste and wastewater (affluents) into aquatic bodies.

**RP143 Effects of 17α-dihydrotestosterone injection on steroidogenic gene expression and plasma sex hormone levels in male mummichog (*Fundulus heteroclitus*)**

*R. Rutherford, A.L. Lister, D. MacLatchy, Wilfrid Laurier University / Biology*

The mechanisms of androgenic endocrine disrupting chemicals in fish are understudied compared to their estrogenic counterparts. Androgen exposure decreases plasma sex hormones, such as testosterone (T) and 11-ketotestosterone (11KT), in fish. Changes in gonadal steroidogenic gene expression may be linked to these depressions. However, in our previous in vitro bioassay of mummichog (*Fundulus heteroclitus*) testis tissue incubated in the presence of the model androgen 17α-dihydrotestosterone (DHT), there was an increase in steroidogenic gene transcript levels during 24 hours of exposure. This is counterintuitive to the decrease of plasma sex hormone levels we have observed in fish exposed to DHT. To further our understanding, an in vivo pilot study was undertaken, in which male mummichog were injected with 1 pg/g, 1 ng/g or 1 µg/g body weight DHT and sampled 6, 12, 18 or 24 hours post-injection to determine the time between injection and reduction of circulating sex steroids. Plasma T and 11KT were significantly depressed at 18 and 24 hours post-injection, in both the 1 ng/g and 1 µg/g treatments. No changes were observed at the 6 or 12 hour time points, or at any time in the 1 pg/g DHT treatment. Based on the pilot study, male mummichog were injected with 1 ng/g or 1 µg/g body weight DHT and sampled 15, 18, 24, 30 or 36 hours post-injection. Levels of steroidogenic gene expression were assessed at time points prior to and during plasma hormone depression. Genes included steroidogenic acute regulatory protein, 3β-hydroxysteroid dehydrogenase and cytochrome P450 17A1. By measuring gene expression levels at 3-6 hour intervals during the onset of plasma steroid depression, the time courses for plasma steroid depression and gene expression activity will be elucidated and indicate potential linkages.

**RP144 Effects of BPAP on thyroid hormone regulation and development in zebrafish embryos**

*S. Lee, Korea Institute of Toxicology / Predictive Toxicology; J. Song, Korea Institude of Toxicology; M. Cho, Korea Institute of Toxicology; S. Yoon, W. Kim, Korea Institute of Toxicology / System Toxicology Research Center*

Bisphenol A (BPA) analogues, such as BPAF, BPAP, BPF and BPS, have been widely used in various commercial products. Bisphenol AP (BPAP) has also been employed as an alternative developer in thermographic sensitive receipt paper. BPAP was detected in various environmental samples such as indoor dust, sediment and sludge and found in food and personal care products. Though endocrine disrupting potentials of BPA analogues (BPF and BPS etc.) were recently reported, the those of BPAP has not yet been well understood, especially on thyroid hormone. Since thyroid hormone is crucial for development and growth, this study was conducted to examine the effects of BPAP on thyroid hormone regulating system and development in zebrafish embryo/larvae model. To this end, zebrafish embryos (< 4 hr after fertilization) were exposed to BPAP (0, 0.04, 0.12, 0.37, 1.0 mg/L) until 144 hpf. Survival and hatching rate of zebrafish embryo was observed during the exposure. Then, 16 genes transcriptions related to thyroid hormone regulation (*crh*, *tshr*, *nkx2.1*, *hhex*, *tshβ*, *slc5a5*, *tg*, *pax8*, *tpo*, *trα*, *trβ*, *ttr*, *dio1*, *dio2*, *dio3* and *ugt1ab*) were analyzed. In addition, enriched gene ontology was identified based on RNA-sequencing. During the exposure, severe mortality was observed in the zebrafish embryos exposed to 1.0 mg/L BPAP. Hatchability and time to hatch was not affected up to non-lethal concentration (0.37 mg/L of BPAP). BPAP did not cause significant changes in gene transcriptions related to thyroid hormone regulation under non-lethal concentrations. Among the tested genes, only the transcription of *tg* gene showed significant increasing trend. Gene ontology enrichment related to thyroid hormone regulation was not found in zebrafish larvae after BPAP exposure. These results might indicate that BPAP was unlikely to affect thyroid hormone regulating genes and development under non-lethal concentrations. Thyroid hormone disrupting potency of BPAP might be relatively lower than that of other BPA analogues. This might be due to the structural differences (tri-ring sturucture) from other BPA analogues. A quantitative comparison among BPA analogues deserve further investigations.

**RP145 Effects of environmentally relevant concentrations of atrazine on early life stage in walleye (*Sander vitreus*)**

*H. Marchand, McGill University / Macdonald Campus / Natural Resource Sciences; B. Barst, McGill University / Dept of Natural Resource Sciences; E. Boulanger, McGill University / Natural Resource Sciences; M. Houde, Environment and Climate Change Canada / Aquatic Contaminants Research Division; J. Head, McGill University / Natural Resource Sciences*

The Richelieu River is an important breeding habitat for over half of the freshwater fish species found in Quebec, Canada, including walleye (*Sander vitreus*), pike (*Esox lucius*), and the endangered copper redhorse (*Moxostoma hubbsi*). Approximately 70% of the Richelieu's watershed is used for agriculture, and elevated concentrations of pesticides, including the herbicide atrazine, have been detected in surface water. Levels of atrazine in two of the main tributaries of the river are consistently within the range of concentrations shown to negatively impact fish health (>0.5 µg/L). In adult fish, atrazine exposure is known to negatively impact reproduction, but relatively few studies have focused on atrazine's impacts to early life stages of fish, particularly in ecologically relevant species. In the present study, walleye was chosen as a study species because of its presence in the Richelieu River, its distribution across northern United States and Canada, and the availability of eggs. Walleye eggs were obtained from a local hatchery and artificially reared in the laboratory matching environmental temperatures. Groups of 100 eggs were placed in plastic egg tumblers which use an air pump to keep the eggs agitated and aerated. Tumblers were placed individually in a glass aquaria containing environmentally relevant doses (0, 0.3, 3, 30µg/L) of atrazine dissolved in acetone (n=3 tumblers per dose for a total of 12 tumblers). The tumblers were effective in preventing the spread of fungus that had been problematic in previous experiments, however, hatching success was low with only 8% of embryos hatching; 84% of eyed eggs hatched suggesting that poor viability may have been related to unfertilized eggs. No significant difference in mortality was observed among treatments, however, atrazine-exposed groups hatched significantly earlier than controls. Twenty-four days post-fertilization, 39% of the high dose group (30µg/L), 13% of the medium dose group (3µg/L), and 3% of the low dose group (0.3 µg/L) had hatched. In comparison, none of the individuals in the control group had hatched. Future work will focus on deformities, DNA methylation (LUMA) and oxidative stress (TBARS) as endpoints. Preliminary results suggest that environmentally relevant levels of atrazine are non-lethal to larval fish, but can influence hatching time, which may negatively affect survival.

**RP146 Effects of hypoxia on the immune response of the eastern oyster (*Crassostrea virginica*)**

*J. Gledhill, A.F. Barnett, University of Mississippi / Department of Biomolecular Sciences; R.J. Griffitt, University of Southern Mississippi / Coastal Sciences; D.J. Gochfeld, M. Slattery, University of Mississippi; K.L. Willett, University of Mississippi / BioMolecular Sciences*

Oysters are extremely important to marine ecosystems. From creating habitat for marine organisms to improving water quality through water filtration, oysters provide several vital ecosystem services. It is critical that efforts are made to maintain healthy oyster reefs to promote resilient marine ecosystems. In recent years however, a large reduction in oyster population has been observed. One study estimates that there has been an approximately 85% reduction in oyster reefs worldwide. Several factors including overharvesting and poor water quality conditions are thought to contribute to this reduction. Hypoxia (dissolved O2 < 2 mg/L) is a another contributing factor adversely impacting oyster reefs. Hypoxic events caused indirectly by algal blooms create a low oxygen environment that can be extremely harmful to marine organisms. In this experiment, subsets of oysters are exposed to differing lengths of hypoxic conditions (3 ,6 , and 9 days) followed by a 5 day recovery period in normoxic conditions (dissolved O2 > 8 mg/L). Oysters were sampled every other day and gill tissue was extracted to observe differential gene expression of immune related genes, thymosin-beta 4 (Tβ-4) and heat shock protein 70 (HSP-70). Additionally, expression of calmodulin and hypoxia inducible factor 1-alpha (HIF1-α) were analyzed by qPCR. Total hemocyte counts were measured to further assess the effects of hypoxia on oyster immune function. The results from the this laboratory study will be compared to those from field deployed oysters in the Mississippi Sound. This work will help determine effects of hypoxia on oyster's immune function and will contribute to the selection of optimal sites for oyster reef restoration efforts. This project is funded by MBRACE (Mississippi Based Restore Act Center of Excellence)

**RP147 Effects of Metformin on Growth and Appetite in Juvenile Fathead Minnows (*Pimephales promelas*)**

*C. Patullo, Oak Ridge Institute for Science & Education at USEPA; M. Nanna, Ithaca College / Department of Environmental Studies and Sciences; M.P. Finegan, Ithaca College / Department of Biochemistry; R. Barone, Ithaca College / Department of Environmental Studies and Sciences; J.M. Lazorchak, USEPA / Office of Research and Development; S. Allen-Gil, Ithaca College / Department of Environmental Sciences and Studies*

Pharmaceuticals and personal care products (PPCPs) characterize a large class of chemicals that leach into the environment through human use and excretion. Recent quantifications of PPCPs in wastewater treatment effluent samples indicate that conventional treatment methods are ineffective at removing many of these chemicals, thus making PPCPs popular subjects of toxicological studies in the past few decades. Recent studies have shown that some pharmaceuticals can impact behaviors such as reproduction, predator avoidance, and food acquisition in some aquatic species at concentrations found in effluent wastewater. This study focuses on the effects of metformin on the growth and appetite of juvenile fathead minnows (*Pimephales promelas*). Metformin is a commonly prescribed medication used to treat type 2 diabetes, metabolic syndrome, infertility, and more. In this study, juvenile fathead minnows were exposed for seven days to three concentrations of metformin: a negative control, an environmentally relevant concentration (1.6 µg/L), and a positive control based on recently published studies (40 µg/L). We observed a significant change in appetite when the minnows were dosed with 40 µg/L of metformin (p=0.00295). However, we did not observe any significant changes in weight gained in any dose at the end of the experiment. It is possible that there may be changes in weight if the exposure period was longer than 7-days. These results suggest that further research is warranted to investigate the connection between metformin exposure, appetite, and growth in juvenile fathead minnows.

**RP148 Enantioselective toxic effects of 2, 2', 3, 5', 6 polychlorinated biphenyls (PCB-95) on anxiety-related behaviors in larval zebrafish**

*P. Ranasinghe, Clemson University / Environmental Toxicology; C.M. Lee, Clemson University / Environmental Engineering and Earth Sciences Department*

2, 2', 3, 5', 6 Polychlorinated biphenyl (PCB-95) is a non-dioxin-like, chiral PCB congener that has been identified as a potent neurotoxicant. Our previous study with racemic (rac-) PCB-95 demonstrated altered behaviors on swimming speed, thigmotaxis and avoidance in *Danio rerio* (zebrafish) at environmentally relevant concentrations. But the differential actions of individual atropisomers of PCB-95 on biological targets have not been studied. In the present study, PCB-95 enantiomers were separated using high performance liquid chromatography (HPLC) and assigned as (+) aR- and (-) aS-PCB 95 to the first and second eluent, respectively. Embryos at the two-cell stage with intact chorions were exposed to different concentrations of racemic and individual isomers of PCB-95 (0.25,0.5 0.75, 1ppm) with two controls (E2 solution and the DMSO). Exposure time was 3 days with 4 days incubation period. At day 7, anxiety-related behaviors were measured with a behavioral assay. Influences on mortality rates, hatching rates and malformations were also observed. Studies on mortality, hatching and malformation indicated that (+) aR-PCB 95 was more potent than the rac-PCB 95 and the (-) aS-PCB 95. The results showed a dose dependent increase in mortality and malformation rates but a decrease in the hatching rates in the (+) aR-PCB 95 and rac- PCB 95 treated groups. These results were further confirmed with the behavioral assay data. Significantly lower swim speed, enhanced thigmotaxis and lower avoidance rates were observed for the (+) aR-PCB 95 compared to the others. In conclusion, enantioselective toxicity of PCB-95 towards the behavior of an organism that links to the developing neuronal networks were investigated and may clarify health risks associated with enantioisomeric enrichment of PCBs in the environment.

**RP149 Evaluation of Nickel-Induced Genotoxicity and Histopathological Alterations in the Liver of *Clarias gariepinus* Burchell 1822 Post-juveniles**

*O. Adebolu, O.T. Aladesanmi, Obafemi Awolowo University / Institute of Ecology and Environmental Studies; M.F. Awodiran, Obafemi Awolowo University, Ile-Ife / Department of Zoology*

Behavioural changes, possible histopathological alterations and effects of nickel on the liver DNA of the exposed fish was evaluated in this study. A range finding test was carried out prior to the definitive test to determine the 96 hour median lethal concentration ($LC_{50}$) of Nickel Chloride. The experiment consisted of two control tanks (each for the male and female set-up) and four (10, 20, 30 and 40 mg/L) acute concentrations of nickel in duplicate with each treatment containing five fishes per tank. Behavioural changes were observed 12 hourly, for 4 days. At the end of the 4-day exposure, two fishes per concentration were randomly selected and their livers excised for histopathological analysis. Genetic analysis was performed, using the Random Amplified Polymorphic DNA Polymerase Chain Reaction (RAPD-PCR) while heavy metal analysis was carried out on these liver samples, using the Atomic Absorption Spectrophotometry. All the treated fish exhibited mild to severe behavioural abnormalities such as unusual and erratic swimming, irregular opercula movements, gulping of air, restlessness, bending and loss of equilibrium. The $LC_{50}$ value for the acute toxicity was 21.45 mg/L. The histopathological examination of the liver samples revealed alterations such as dialated sinusoids that are not radially apparent, dialated central veins, numerous intracytoplasmic vacuolations, distorted histoarchitecture as well as lyphmphocytic infiltrations. The RAPD analysis showed DNA damage in the liver of treated fish samples compared to the control. Electrophoretic images revealed bands mostly from 200 to 800 bp and more bands were revealed in female fish samples as compared to the male fish samples. The study concluded that Nickel Chloride altered normal behavioural patterns, caused several histopathological alterations and DNA damage especially in female *C. gariepinus.*

**RP150 Histological and behavioral evaluation of the livebearer *Jenynsia multidentata* exposed to glyphosate: A comparative analysis of Roundup® formulations**

*C.D. Martins, J.A. Albañil Sánchez, Federal University of Rio Grande / Biological Sciences*

Roundup formulations are herbicides whose active principle is glyphosate. They are also composed of other ingredients, such as surfactants that are more toxic than pure glyphosate to fish. However, there are few studies comparing the effects of different formulations commercialized worldwide. Therefore, this study aimed to evaluate and compare the toxic potential of the Roundup formulations through histological and behavioral alterations in fish. For that, males and females of the neotropical fish *Jenynsia multidentata* were acutely exposed to Roundup Original® (RO), Roundup Transorb® (RT) or Roundup WG® (RWG), at a fixed concentration of 0.5 mg/L of glyphosate. This concentration is close to the maximum glyphosate limits found in the environment and is non-lethal to *J. multidentata*. The three formulations caused histological damage to the liver, gills and brain of *J. multidentata*, which increased over the exposure time (24 to 96 h). Females were more tolerant to RO, RT and thereafter to RWG, respectively. Males did not exhibit these differences in sensitiveness with formulations. The RWG caused more damage in liver and gills and RT in the brain. Behavior tests performed after 96 h of exposure were: open-field test, social interaction, aggressiveness, and long-term memory (LTM) tested in an inhibitory avoidance apparatus. Results showed that the RO, RT and RWG formulations caused neurotoxicity, reaching behavioral patterns. It was observed that *J. multidentata* present a natural anxious conduct that significantly increases under RWG exposure. This formulation also caused a decrease in social interaction of livebearer. On the other hand, RO caused depression in the animals more than other formulations. The LTM was negatively affected by the presence of RT and RWG. Overall, RWG formulation was the most aggressive for *J. multidentata* exhibiting a more diffuse action, whilst the RT seems to have the central nervous system as a target-organ. The results reinforce the potential use of the *J. multidentata* as an indicator of the presence of agrochemicals. Differences between formulations toxicity and their effects are directly related to the inclusion of other components besides glyphosate, which are described in their respective labels as "inert" compounds. The comparison of the toxic potential of glyphosate-based herbicides is important to give support to the governmental organizations to set protective rules for the ecosystems and for human health.

**RP151 In vitro cytotoxicity of B[a]P, PCB 77, PCB 126, and PFOA in gray whale (*Eschrichtius robustus*) skin fibroblasts**

*C. Wittmaack, Texas Tech University / Department of Environmental Toxicology; J.D. Pierro, Texas Tech University / TIEHH / Environmental Toxicology; J.G. Surles, Texas Tech University / Department of Mathematics and Statistics; J. Jacobsen, V.E. Enterprises / Department of Biological Sciences; A. Lang, NMFS Southwest Fisheries Science Center / NOAA Fisheries / Southwest Fisheries Science Center; C.A. Godard-Codding, Texas Tech University / TIEHH / Department of Environmental Toxicology*

The gray whale (*Eschrichtius robustus*) is long-lived and migratory, often traveling and feeding close to dense coastal human populations. Under the MMPA, separate eastern and western North Pacific stocks are recognized, and the small WNP stock is listed as Endangered under the ESA. Persistent marine contaminants such as polychlorinated biphenyls (PCBs) (historically produced for industrial purposes), polycyclic aromatic hydrocarbons (PAHs) (produced from the burning of fossil fuels and wood), and per/poly-fluorinated compounds (PFCs) (found in stain repellents and anti-stick cookware) have been detected in cetacean blubber. However, little is known about the effects of these contaminants in gray whales. We aim to understand whether organic pollutants may be cytotoxic in gray whale tissue and whether these toxicants are of concern for the species. Due to their protected status, cell culture is invaluable as it is minimally invasive and allows for multiple investigations using a single biopsy. We cultured primary fibroblasts from skin biopsies obtained from three free-swimming gray whales off the coast of California. Each biopsy was minced and placed under a coverslip in a gelatin coated cell culture dish. Cells were cultured in DMEM/F12 media supplemented with 15% cosmic calf serum, 1% penicillin/streptomycin, 1% glutamax, and 0.1% sodium pyruvate. Cells were incubated at 37°C in a humidified atmosphere of 5% $CO_2$. We analyzed cytotoxicity via MTT (methylthiazolyldiphenyl-tetrazolium bromide) and LDH (lactate dehydrogenase) assays. Toxicants selected for our study were benzo[a]pyrene (B[a]P) or PCB 126 or PCB 77 in concentrations of 10µM, 1µM, 0.1µM, or 0.01µM or lastly perfluorooctanoic acid (PFOA) in concentrations of 500µM, 50µM, 5µM, 0.5 µM, or 0.05µM . Exposure time points were 24h, 48h, 72h, and 96h for each toxicant. Cytotoxicity was determined colorimetrically via spectrophotometer for both MTT and LDH assays. Preliminary results indicate that cellular viability was significantly reduced after exposure to B[a]P, PCB 126, PCB 77, and PFOA at various concentrations and time points. Additional data analyses are underway.

**RP152 In vivo quantification of xenobiotic metabolism in freshwater snails**

*A.M. Simpson, Penn State Behrend / Zoology; D. VanHook, Pennsylvania State University / The Behrend College / Biology; P.D. Jeyasingh, J.B. Belden, Oklahoma State University / Integrative Biology*

Mixed function oxygenases (MFOs) and esterase enzymes comprise an organism's first line of defense against xenobiotics. MFOs exhibit broad substrate specificities, which allow them to alter/detoxify a wide variety of endogenous and exogenous compounds. Consequently, MFO and esterase activity plays an important role in dictating sensitivity to xenobiotics. The current study aims to validate an in vivo assay that quantifies metabolic activity in response to multiple MFO and esterase substrates simultaneously in freshwater snails (*Helisoma* and *Physa* spp.). Organisms were exposed to 6 µM concentrations of four substrates—4-nitroanisole (4-NA), 7-ethoxycoumarin (7-EC), 7-ethoxyresorufin (7-ER), and 1-naphthyl acetate (1-NpA)—for six hours. Subsequently, the metabolites of these substrates were extracted from the experimental matrix via supportive liquid extraction. The analytes within each sample were separated and quantified using an LC-MS, after which a "metabolic profile" was constructed. This non-destructive assay permits a comprehensive evaluation of xenobiotic metabolism that could facilitate population-level assessments of contaminant sensitivity.

**RP153 Inter-generational impacts of crude oil exposure on genome-wide expression in developing Gulf Killifish embryos**

*J. Park, UC Davis / Environmental Toxicology; C.D. Hess, C.A. Brown, F. Galvez, Louisiana State University / Department of Biological Sciences; A. Whitehead, University of California, Davis / Environmental Toxicology*

A growing body of research demonstrates that biological impacts of environmental toxicants can persist across generations. Oil spills are of ecotoxicological concern, because they occur frequently, impact large geographic areas, affect diverse species, and can occur in sensitive habitats. Much research has sought to reveal impacts of oil exposure on development and physiology, including its underlying mechanisms. In contrast, relatively little is known of how toxicity could persist across one or more generations. We characterized the developmental and inter-generational impacts of laboratory crude oil exposure in Gulf killifish using transcriptomic and physiological endpoints. After exposing adult killifish to weathered crude oil and control conditions, we tested whether offspring from exposed parents had altered gene expression and sensitivity to oil toxicity during embryogenesis. We found that parental oil exposure disrupted developmental gene expression patterns in their offspring, and identified molecular responses that are potentially involved in mechanisms of intergenerational crude oil toxicity.

**RP154 Investigation on oxidative and genotoxic stress effect of heavy metals and pesticides exposure on tardigrade and the antioxidative effect of vitamins**

*O. Ojekunle, Texas Southern University / Department of Environmental Science and Technology / Environmental and Interdisciplinary Science; A. Sodipe, Texas Southern University / Biology*

The exhaustive use of chemicals, like pesticides, heavy metals and some drugs leads to chronic exposure to lower doses of these toxicants. Cadmium and copper are highly toxic environmental contaminants, though cadmium is more toxic. According to literature, these metals form a serious hazard to the public health and a threat to most life forms. Cadmium and copper are potent toxicants that are commonly found in aquatic environment as a result of anthropogenic activities (Hygum et al., 2017). Studies have shown Copper to inhibit osmoregulatory enzymes and induce oxidative stress, while Cadmium inhibit cell proliferation due to its carcinogenicity. Human genotoxicity and carcinogenicity due to exposure to insecticide represent a prominent public health hazard. Mammals utilize specific pathways like apoptosis to ameliorate or reduce the resulting hazard from DNA damage. (Bock et al., 2015). Lufenuron and Chlorfluazuron are both pesticides. Exposure to these pesticides have been studied to have adverse effects like, genotoxic stress and reproductive inhibitors, respectively. Tardigrades are microscopic aquatic animals renowned for their tolerance towards extreme environmental conditions, this study will investigate their tolerance towards heavy metals and pesticides and how to ameliorate these effects with antioxidants (vitamins). Antioxidants are substances that may protect the cells against the effects of free radicals, they are intimately involved in the prevention of cellular damage which is the common pathway for cancer, aging, and a variety of diseases. In the laboratory, tardigrades will be exposed to varying concentrations of heavy metals (cadmium and copper) and pesticides (Lufenuron and Chlorfluazuron) by simulating the environmental route of exposure. Genomics combined with culturing may identify tardigrades that may be tolerant to these extreme conditions. After discovering these effects on the tardigrade cells, the tardigrades will be treated with antioxidant (vitamins) which has the ability to sequester the heavy metals and prevent free radical formation by the pesticides. I expect to gain a better understanding of the mechanism of action of heavy metals and pesticides in the formation of free radicals, genotoxic stress, inhibiting reproduction and inducing carcinogenic response. Finally, I hope to develop an understanding of how vitamins can be used to ameliorate these adverse toxic insults induced by pesticides and heavy metal exposure.

**RP155 Modeling the effect of branching on the aquatic ecotoxicity of surfactants and its application for effect assessment and testing decisions**

*M. Fan, The Procter & Gamble Company / Environmental Stewardship and Sustainability, Global Product Stewardship; S.E. Belanger, The Procter & Gamble Company / Global Product Stewardship; J. Brill, J.M. Rawlings, K.A. Connors, The Procter & Gamble Company / Environmental Stewardship and Sustainability*

Surfactants play important roles in consumer product formulations including laundry and dish detergents, shampoos, and conditioners. Environmental fate and effects of those surfactants have been studied extensively providing a long history of safe use. Linear and essentially linear surfactants have been worked most intensively with ecotoxicological tests and mesocosms leading to well established aquatic predicted no-effect concentrations (PNEC). For example, the anionic surfactant category of alcohol ethoxy sulfates (AES), PNECs are based on species sensitivity distributions using chronic effect and mesocosm data normalized to an environmentally relevant structure. However, for branched surfactants which can meet biodegradability requirements, assessment and predictive tools are greatly needed as much less testing data is available. Conventional wisdom suggests branched surfactants should be less toxic to aquatic species than essentially linear ones, as branching increases the hydrophilic nature of surfactant. This work intends to quantify ecotoxicity of branched surfactants by quantitative structure activity relationship (QSAR) modeling and validate the approach using new ecotoxicity data. The modeling methodology started with calculating log P for individual components of surfactant mixtures employing a position-dependent branch factor, then determining acute and chronic toxicity based on QSAR for each component, lastly deriving entire mixtures' toxicity by a toxic unit approach. Examples of aliphatic branched AESs were provided with model prediction and recent experimental results on the invertebrates *Daphnia magna* and *Ceriodaphnia dubia*. The majority of the ratios of model and measurement of effective concentrations (EC50) fell within a factor of three with less variability on more toxic compounds. By integrating literature data, 60% of model predictions were within two-fold of measured values and 80% within a factor of three. One of the applications for this modeling work was to quantify mixture toxicity differences of branched versus linear surfactants. The case study suggested that for lesser branched AESs, ecotoxicity difference is not significant, however, for highly branched, noteworthy reduction for ecotoxicity could be expected (e.g., acute EC50 increase of 60-80%). The findings are currently being applied for effect assessment, aiming prioritization and reduction of ecotoxicity testing.

**RP156 Molecular biological analysis of biodegradation behavior in the ready biodegradability test**

*Y. Takano, S. Takekoshi, K. Takano, Y. Matoba, M. Sato, Sumitomo Chemical Co Ltd / Chemical Safety Assessment Group*

Ready biodegradation test OECD TG 301 has been required under the Japanese Chemical Substances Control Low (JCSCL) for chemical safety management. The test shall be conducted at a quite high concentration and hence, bioavailability to microorganisms is too low to reflect a biodegradation profile in an actual environment especially for poorly water soluble chemicals. In addition, the test shall be done with the standard microbial inoculum cultivated in a synthetic sewage containing mainly glucose and peptone for at least one month and consequently, the inoculum has a lower degradation activity than that in an actual environment, leading to false negative outcomes especially among ready biodegradation tests. Therefore, ready biodegradation test OECD TG 301F has been introduced under JCSCL since April 2018, in which an inert carrier or an emulsifying agent can be used to improve bioavailability to microorganisms and a microbial inoculum taken from a treatment plant receiving predominantly domestic sewage can be used to reflect degradation activity under an actual environment. Nonetheless, there are few studies to clarify the influence of an inert carrier or an emulsifying agent on flora of the degrading microorganisms or to investigate differences in microflora between the standard microbial inoculum and the inoculum taken from a sewage treatment plant. In this study, a silica gel and Tween 80 were used as an inert carrier or an emulsifying agent, respectively, to improve chemical dispersity. Dibenzofuran, anthraquinone, 2-ethylanthraquinone and tris(2-ethylhexyl)trimellitate were used as poorly water soluble chemicals classified as not readily biodegradable under JCSCL. One hundred mg/L of each chemical was exposed to 30 mg/L of the standard microbial inoculum or the inoculum taken from a municipal sewage treatment plant, and microbial DNA was extracted from the degrading microorganisms when remarkable biodegradation was observed in monitoring the biochemical oxygen demand curve or HPLC analysis, and then the microflora was investigated by a metagenomic analysis of bacterial 16S rRNA (V3-V4 region) using next-generation sequencer. Several cases of variations in microbial community structure occurred during the biodegradation, and further analyses were conducted to determine dominantly increasing microorganisms. These results are reported in this presentation.

**RP157 Molecular, Physiological and Behavioral Responses of Embryo-Larval Zebrafish Exposed to Types I and II Pyrethroids**

*O.M. Awoyemi, J. Crago, Texas Tech University / Environmental Toxicology / The Institute of Environmental and Human Health (TIEHH)*

Pyrethroids are highly toxic to aquatic species. Most toxicity studies assess only single chemicals, which makes it difficult to assess relative toxicity across classes of pyrethroids. There are limited studies comparing the developmental toxicity of type I and II pyrethroids in aquatic systems at environmentally relevant concentrations. The goal of this study was to compare the molecular, physiological and behavioral effects of pyrethroid exposures in larval zebrafish (Danio rerio). Zebrafish embryos were exposed to type I (bifenthrin, permethrin) and type II (deltamethrin, $\lambda$-cyhalothrin, fenvalerate, esfenvalerate) pyrethroids at 1000, 10, 0.1, 0.01 µg/L starting at 5 h post-fertilization (hpf) through 5 d post-fertilization (dpf). Behavior assays assessing swimming behavior (distance traveled and velocity) were conducted at 5 dpf. The stability of pyrethroids across the 5 days was analyzed using LC-MS/MS. Gene expression using RT-qPCR, total reactive oxygen species (ROS), and enzymatic activities were determined to assess relative toxicity amongst the pyrethroids. The initial concentrations of all six pyrethroids were significantly ($p< 0.05$) reduced at days 3 and 5 of the exposure timeline. However, both the type I and II pyrethroids had significant ($p< 0.05$) effects on the behavior of the zebrafish larvae, as compared to control. Type I pyrethroids demonstrated a U-shaped dose response with behavioral endpoints at 5 dpf, whereas type II pyrethroids showed no specific pattern in dose response with behavioral endpoints as compared to the control. The type I and II pyrethroids had significant ($p< 0.05$) effects on the total ROS production, as well as the expressions of certain genes including Nrf2a, Cas9 and p53, which were indicative of oxidative stress in the zebrafish embryo-larval development. Further studies are being carried out to assess the enzymatic activities in zebrafish exposed to these pyrethroids.

**RP158 Morphometric Effects of Various Microplastics on Sac Fry Zebrafish**

*G.M. Moreno, Rutgers University / School of Environmental and Biological Sciences; K.R. Cooper, Rutgers University / Environmental and Occupational Health Science Institute; E. Ravit, Rutgers University*

Microplastics (1nm to 5mm) and plasticizers are ubiquitous in waterways, beaches, sediments and biota across the world. It is estimated that since the emergence of plastic in the 1950s, ~18 trillion pounds of plastic have been produced. Ingestion of microplastics by various marine species and accumulation of plasticizers has been documented and is of growing concern. Additionally, microplastics act as a carrier for the transport of persistent organic pollutants, increasing the hazard to aquatic species. Microplastics vary in composition based on its monomeric component and the specific plasticizer, i.e. chemical additives that increase the plasticity or viscosity of plastics. The toxic effects associated with the components that comprise the polymerized plastic are not well characterized. The results presented here examine gross morphological variations in sac fry zebrafish as a result of exposure to weathered microplastics and pure plastic polymers. Embryos were exposed from 3 hours post fertilization (hpf) to 96 hpf with samples of weathered microplastics from Newark Bay, NJ, as well as commercially available pure plastics at concentrations of 1 µg/mL and 10 µg/mL. The Newark Bay microplastics were analyzed via pyrolysis GC-MS to determine composition. Pyrolysis GC-MS determined that the three samples were composed primarily of polyethylene (PE), polypropylene (PP) and polyvinyl chloride (PVC). Morphometric data were statistically analyzed, and no significant change was noted between the controls and the treated groups in the embryonic Zebrafish samples for the Newark Bay, Fenton treated, weathered samples. The commercial microplastics tested included: PE (low, medium and high density), polystyrene (PS), PVC, sodium polyacrylate (SPA), polyethylene terephthalate (PET), polyurethane (PU), and polymethyl methacrylate (PMMA). Significant changes were seen in total body length in the polyethylene 10 µg/mL exposure group. Significant changes were seen in pericardial sack size in polyethylene low density (LD) 10 µg/mL, polyethlene high density (HD) 1 µg/mL and 10 µg/mL, and polystyrene 1 µg/mL and 10 µg/mL exposures. Preliminary gross observations show pericardial sac edema as a common endpoint. (NJAES #01201)

**RP159 Nephrotoxic effects of glyphosate and Rodeo ® through water exposure on largemouth bass**

*M. De Maria, K.J. Kroll, C. Silva-Sanchez, University of Florida / Department of Physiological Science; M. Walsh, University of Florida / Aquatic Animal Health Program; N.D. Denslow, University of Florida / Physiological Sciences*

Glyphosate is the most widely used non-selective broadleaf herbicide in the world including Florida. It has been used extensively for weed control on non-croplands, with glyphosate tolerant crops and a ripener for sugarcane. Farmers chronically exposed to glyphosate have shown unusual kidney disease. Glyphosate can be found in waterways as run off from crops or be directly sprayed into water bodies to control overgrowth of aquatic vegetation (Rodeo® formulation). Glyphosate can persist for 60-70 days in water and it has also been detected in the ocean. With its extensive use and slower than expected degradation, aquatic animals can be chronically exposed to glyphosate. Long-term exposure experiments with animal models, like fish, have shown reproductive impairments and kidney disease. The toxicity mechanism is through the formation of reactive oxygen species. Our objective is to assess kidney damage in largemouth bass after chronic exposure to glyphosate and Rodeo®. We exposed male individuals (n=4/tank, 4 replicates/treatment) to 0.5 and 10mg/L concentrations of glyphosate and Rodeo® (EPA Reg. No. 6219-324, chemically equivalent concentration) in water for 28 days. Our lowest concentration was similar to the EPA maximum concentration allowed for drinking water. Fresh exposure solution was made every 5 days, and 70% of the tank water was changed daily. Actual concentrations of glyphosate in exposure solutions were verified by LC-MS/MS. Our preliminary histopathology results, show apoptosis and necrotic tissue in the high-dose treatment and not in the control. We will analyze changes in gene expression through RNA sequencing of the trunk kidney. We expect to detect upregulation of genes related to kidney damage such as kidney injury molecule (KIM-1), beta-2-microglobulin and neutrophil gelatinase-associated lipocalin (NGAL) in the higher-doses in comparison to control. We expect to detect enriched gene pathways associated with apoptosis and oxidative damage. Our research will identify possible molecular markers for kidney damage as a consequence of exposure to glyphosate or Rodeo® in fish that can be extended to other species exposed through their environment.

**RP160 Neurobehavioral effects of organophosphates on embryo-larval zebrafish at environmentally relevant concentrations**

*C. Schmitt, T M.M. McManus, N. Kumar, J. Crago, Texas Tech University / Environmental Toxicology / The Institute of Environmental and Human Health (TIEHH)*

Organophosphates are common surface water contaminants in both urban and agricultural landscapes. Neurobehavioral effects on larval fish are known to occur at concentrations higher than those reported; however, behavioral effects have yet to be investigated at environmentally relevant concentrations. For this ongoing study, the developmental neurobehavioral effects of organophosphate exposure on embryo-larval zebrafish (*Danio rerio*) were assessed using a larval zebrafish behavior assay. Five common organophosphates (chlorpyrifos-oxon, methyl-parathion, malathion, dichlorvos, and diazinon) were assessed individually at environmentally relevant concentrations. Embryos were exposed to chlorpyrifos-oxon at 1mg/L, which resulted in fatality of all embryos. Subsequent embryos were exposed to organophosphates at 100 µg/, 10 µg/L, 100 ng/L, and 10 ng/L starting at 4 h post-fertilization (hpf) to 5 d post-fertilization (dfp). Behavior assays assessing swimming behavior (distance traveled and velocity) were conducted at 5 dpf. Data was analyzed using one-way ANOVA with Tukey HSD post hoc test. Zebrafish larvae were tested individually at 100 µg/L chlorpyrifos-oxon ($p < 0.05$) and 100 µg/L diazinon ($p < 0.05$) and data revealed that zebrafish larvae traveled a significantly lesser distance than the controls. All chlorpyrifos-oxon treatment groups travelled lesser distance than the control group. Velocity of larva exposed to 100 µg/L chlorpyrifos-oxon and 100 µg/L diazinon decreased significantly compared to their control groups. Preliminary chlorpyrifos-oxon and diazinon data indicates behavioral changes at 100 µg/L in larva. All organophosphates displayed a decreasing trend in distance traveled and velocity relative to their controls. Relative expression of AChE mRNA indicated a downward trend in fold change for all organophosphates, and acetylcholinesterase (AChE) activity assessments indicated a downward trend for chlorpyrifos-oxon and malathion. Ongoing carboxylesterase (CES) assessments suggest an upward trend in activity for chlorpyrifos-oxon, methyl-parathion, and malathion. Investigation into the neurobehavioral effects of organophosphates' continues.

**RP161 NPDES Whole Effluent Toxicity (WET) Toxicity Identification Evaluation/Toxicity Reduction Evaluation (TIE/TRE) Poster Abstract**

*B. Staples, USEPA Region 4 / Water Protection Division, NPDES Permitting; S. Zavala Bogdan, USEPA Region 6 / NPDES Permits and TMDL Branch; L.J. Phillips, USEPA HQ / OWM / WPD / SRB; K. O'Brien, USEPA Region 2 / NPDES Section; R. Stuber, USEPA Region 9 / Water Permits Division / NPDES Permits Section*

Under the National Pollutant Discharge Elimination System (NPDES) permits program, the use of aquatic toxicity testing such as whole effluent toxicity (WET), along with Toxicity Identification Evaluations and Toxicity Reduction Evaluations (TIEs/TREs) where necessary, have been instrumental in addressing identified toxic impacts to aquatic life. The focus of this presentation is to provide case examples of TIEs/TREs from approximately the last five years, conducted using the recommended approaches in Environmental Protection Agency's (EPA) TIE/TRE guidance documents. The examples are derived from actual NPDES TIE/TRE cases which were successful in reducing or eliminating sources of toxicity. A brief list of key recommendations from EPA's TIE/TRE procedures will be provided and further illustrated by the case examples, which include descriptions of some of the diagnostic approaches used to further assess ambient or effluent toxicity data that indicated excursions of state aquatic life water quality standards. In this presentation, we will provide an overview of some of the important scientific principles, key technical considerations and EPA recommendations that should be considered when conducting TIEs/TREs. The presentation will cover the primary advantages of a well-planned and executed TIE or TRE, especially for resolving possible impacts to aquatic organisms and for making decisions about water quality protection of aquatic life. We will discuss how TIEs/TREs can provide valuable insights into the causes and sources of toxicity as well as some recommended approaches for resolving ecological impacts to aquatic communities due to exposure to pollutants. *The views expressed in this presentation are those of the author(s) and do not necessarily represent the views or policies of the Agency.*

**RP162 Partitioning of azithromycin into Chinook salmon eggs from American River water**

*E. Tjeerdema, M.V. Maier, R.S. Tjeerdema, University of California, Davis / Environmental Toxicology*

Azithromycin (AZ), a potent antibiotic and USEPA Emerging Contaminant of Concern, has been found in aquatic systems all over the world. After release into the environment through sewage effluent, AZ can be found in both soil and water where organisms can be exposed, however very little is known about AZ in aquatic systems. California river systems are integral to the economy as well as vital for endangered species like salmonids. Water and conditions from the American River, a spawning ground for salmonids such as the Chinook salmon (Oncorhynchus tshawytscha), were used in this study to represent California river systems. Winter run Chinook salmon eggs (6.01 ± 0.02 g) were shaken in microcosms consisting of 200 mL of filtered American River water at 10°C ± 1 for 24 h. After equilibration, microcosm water was dosed with 5.32 x 10?? µM ¹?C radiolabeled AZ plus 5.34 x 10?¹ µM unlabeled AZ. Microcosms were sacrificed at 0, 4, 8, 16, 25, and 49 h, at which times eggs, water, and glass sorption were measured. Samples were analyzed via Liquid Scintilation Counter. The concentration of AZ sorbed to the eggs reached equilibrium after 25 h. After 49 h, less than 1% of the original dose of AZ had partitioned into the eggs from the surrounding water. Ratio of egg mass to water volume was explored using varying egg masses (3.02 ± 0.01, 12.00 ± 0.02, and 16.01 ± 0.01 g). The eggs were exposed as above and measurements taken at 48 h. A linear trend was observed between egg mass and the total AZ sorption into the eggs ($R^2$ = 0.95). Based on this study, AZ does not readily sorb to salmon eggs, despite having a high potential to concentrate in tissue.

**RP163 Reconstructing trace element exposure histories of fish using otolith microchemistry in watersheds that contain energy-extraction industry activity**

*N. Bailes, The Ohio State University / Environmental Science Graduate Program; R.P. Lanno, Ohio State University / Department of Evolution, Ecology, and Organismal Biology*

The proliferation of unconventional oil and gas wells that utilize high volume horizontal hydraulic fracturing (HVHHF) technology has yielded enormous quantities of highly saline produced waste waters. Despite the implementation of various safety protocols, releases of these waste waters into surface waters has occurred. In the absence of continuous monitoring of baseline water chemistry, it is difficult to quantitatively assess the exposure of aquatic organisms to contaminants originating from HVHHF processes. Analysis of fish otoliths is one potential method for quantitatively assessing contamination exposure in the absence of continuous monitoring. We collected sunfish (*Lepomis* sp.) from various watersheds throughout eastern Ohio. Each site was selected based on its proximity to energy-related resource extraction activities. Fish were sampled from watersheds that encompass surface coal mining operations, sites of acid mine drainage, HVHFF activities, as well as a reference watershed where no ongoing energy-related resource extraction activities had taken place. Through laser-ablation inductively-coupled plasma mass spectrometry (LS-ICP-MS), we characterized otolith trace metal content ($Li^{7}$, $Na^{23}$, $Mg^{24}$, $Mg^{25}$, $As^{75}$, $Sr^{88}$, $Cd^{111}$, $Ba^{137}$, $Ba^{138}$, $Hg^{200}$, $Pb^{208}$, $S^{32}$, $Cr^{52}$, $Fe^{56}$, $Ni^{60}$, $Zn^{64}$) for fish from each of these sites in order to explore the potential of these data to discriminate between the trace element signatures associated with various of energy-related resource extraction processes. We will also discuss the relationships between accumulation of the different metals over the lifespan of the sunfish and over the time of development of new extraction industries in the watershed.

**RP164 Responses to Hydroxychlorothalonil and Dicloran Exposure by *Menidia beryllina* in the Presence of Varying Salinities and Sunlight**

*E.N. Vebrosky, Louisiana State University / Department of Environmental Sciences; W. Xu, Louisiana State University AgCenter / Renewable Natural Resources; K. Armbrust, Louisiana State University / Environmental Sciences School of the Coast and Environment*

Hydroxychlorothalonil is the primary soil degradation product of the fungicide, chlorothalonil, which is applied to crops, turf, and ornamentals; unlike chlorothalonil, hydroxychlorothalonil is readily re-suspended into the water column and can undergo photodegradation in the presence of sunlight. Dicloran is a systemic fungicide applied to a variety of crops throughout the western and southern United States including celery, lettuce, and sweet potatoes; it also can undergo photolysis degrading through a quinone-hydroquinone pathway. Both fungicides have similar reported photodegradation pathways, intermediate degradation products, and differences in distribution between seawater and freshwater. Inland silversides (*Menidia beryllina*) can be found throughout North America and have a wide tolerance of salinities. Using varying salinities, the differences in the response to potential toxicity and phototoxicity of dicloran and hydroxychlorothalonil can be observed in inland silversides. At concentrations as low as 0.10-mg/L dicloran, sub-lethal impacts such as an upregulation in the gene expression of silversides can be observed at salinities of 25 ppt; at concentrations as high as 0.50-mg/L, total mortality can be observed in the presence of sunlight. At 12 ppt salinity, total mortality can be observed at concentrations as low as 0.10-mg/L dicloran in the presence of sunlight, while 0.17-mg/L dicloran showed roughly 80% mortality at salinities of 5.5 ppt.

**RP165 RNA-sequencing helps understanding the effects of benzotriazole UV-stabilizers in dietary exposed juvenile rainbow trout (*Oncorhynchus mykiss*)**

*M. Giraudo, T.L. Colson, A.O. De Silva, P. Gagnon, Environment and Climate Change Canada / Aquatic Contaminants Research Division; L. Brown, Environment and Climate Change Canada; M. Houde, Environment and Climate Change Canada / Aquatic Contaminants Research Division*

Phenolic benzotriazole UV-stabilizers (BZT-UVs) are widely used as additives to protect from light-induced yellowing and degradation in a variety of products (e.g., paints, coatings). Despite their widespread presence in aquatic ecosystems and persistence in the environment, information on the effects, toxicity or modes of action of these compounds remain largely unknown. The objectives of the present study were to evaluate the chronic effects of two BZT-UVs, 2-(2H-benzotriazol-2-yl)-4,6-bis(1-methyl-1-phenylethyl)phenol (UV-234) and 2-(2H-benzotriazol-2-yl)-4,6-di-tert-pentylphenol (UV-328), in juvenile rainbow trout chronically exposed (28-d) through diet. Chemical analyses of livers from exposed trout showed a higher accumulation of UV-328. Additive and synergistic effects of the UV-328 and UV-234 mixture were also observed on the accumulation of each compound in the liver (i.e., 6 and 2 times the nominal concentrations in the amended feed, respectively). A 120-h depuration period at the end of the 28-d exposure showed similar and limited depuration rate of 25.9 and 28.3% per day for UV-234 and UV-328, respectively. RNA-sequencing analyses of exposed trout liver were used to identify the transcriptional effects of BZT-UVs individually or in a mixture. Results revealed specific effects of each compound on gene transcription profiles; UV-234 affected mainly genes involved in cellular metabolism (cholesterol, glucose, energy), while UV-328 induced the transcription of many ribosomal proteins and down-regulated the transcription of genes involved in immune responses. Additive effects of the mixture of both BZT-UVs were observed on the regulation of two immune-related genes. Quantitative real-time PCR measurements confirmed the effects of UV-234 and UV-328 on the transcriptional regulation of a suite of candidate genes. Further analyses of related protein activity will help identify potential biomarkers of exposure and characterize the modes of action of BZT-UVs in fish.

**RP166 Suitability of effect-based bioassays for mixture effect elucidation**

*R. Altenburger, G. Jakobs, W. Busch, Helmholtz Centre for Environmental Research – UFZ GmbH / Bioanalytical Ecotoxicology*

In the environment, chemicals occur in complex mixtures rather than individual entities. Hence, environmental quality monitoring faces the challenge to comprehensively assess a multitude of contaminants and potential adverse effects. To meet this challenge, effect-based methods have been suggested as complements to analytical characterization of complex pollution patterns. Here, we present an interlaboratory study which investigates the suitability of effect-based bioassays for mixture effect elucidation by conducting the toxicological potential of individual, high priority pollutants and their mixtures with a panel of effect-based bioassays. The tested compounds were of diverse chemical structure and unique known mode of action (MoA). The bioassay panel consisted of whole organism assays measuring apical effects and cell-based bioassays with more specific effect observations. After single substance dose-response determination, bioactive substances were selected and two mixtures modeled. One mixture contained at least two active components for each bioassay that was able to detect single substance toxicity, thus allowing mixture effect elucidation within the bioassay panel to the greatest possible extent. A second mixture consisted of the same components but in environmentally relevant concentrations, thus aiming at reflecting naturally occurring circumstances and illustrating the impact of low-concentrated chemical mixtures on various organisms. Hence, observed mixture effects were compared against two mixture effect prediction models derived from additivity expectations, the model of concentration addition (CA) and independent action (IA). Most of the assays detected the mixture response of the active components as predicted even against a background of inactive contaminants. When none of the mixture components showed any activity by themselves then the mixture was also without effects. With one exception, the mixture effects observed using apical endpoints mainly appeared within the prediction window set by both applied models, whereas the specific cell- and organism-based endpoints resulted in mixture responses according to the model of CA. Concluding, most effect-based bioassays were able to quantitatively detect the predicted mixture effects, thus illustrating the importance of including mixture toxicity evaluation in risk assessment and further supporting the idea of combining chemical with bioanalytical monitoring tools.

**RP167 Suitability of growth rate in the marine amphipod *Parhyale hawaiensis* as an endpoint for chronic toxicity assessment**

*P. Kushima Assano, O.J. Diehl, School of Technology UNICAMP; G.D. Umbuzeiro, School of Technology -UNICAMP / LEAL; R. de Oliveira, School of Technology UNICAMP*

*Parhyale hawaiensis* is a marine amphipod with worldwide circum-tropical distribution. Recently, acute ecotoxicological procedures were standardized for these model organisms. However, it's potential for chronic toxicity assessment still unclear. The segmented body of *Parhyale* consists of the head, the thorax, and the abdomen. The specialization of *Parhyale* appendages offers interesting material to study the molecular and cellular biology, morphogenesis and growth, which is a standard endpoint in chronic tests. *P. hawaiensis* has become a model for evolutionary and developmental biology research, but no consistent information about growth rate was found in the literature. Thus, the aim of this study was: (i) obtain data on growth of *P. hawaiensis* during 100 days in a miniaturized system; (ii) determine the best time interval to perform chronic testing, based on growth rate data. Two independent experiments were performed. Each test consisted of 100 days, being 60 organisms studied in the first test and 72 organisms in the second. On the first day of observation, organisms at ages < 7 days were taken from the laboratory culture, photographed under a stereomicroscope and transferred to 12-well microplates containing 4 mL of salt water. Three times per week, water was partially renewed and organisms were fed. The organisms were monitored daily for molts and mortality. Every week a photo was taken to study the growth rate, more specifically in terms of cephalothorax length (mm). It was possible to observe a linearity of growth in both tests, growth rate global of 0.017 mm.day $^{-1}$ and 0.016 mm.day $^{-1}$ on tests 1 and 2, respectively. The measured mean lengths of cephalothorax were 1.300 mm and 3.122 mm, on days 0 and 100 respectively of test 1, and 1.215 mm and 2.782 mm, on days 0 and 100 respectively of test 2. Significant growth is observed from 21 days of observation for both tests (ANOVA on ranks, Dunn's ($p < 0.05$)). A decrease in the growth rate is observed from the day 70 for test 1 and 63 for test 2. Thus, to ensure the sensitivity of the endpoint, duration of the test should last at least 21 days and at most 63-70 days. More experiments are going to be conducted with the exposure of neonates to selected toxicants to verify if will effect on growth rate in the developed experimental conditions. *Acknowledgement:* CNPQ (CNPq-PVE Process: 400362/2014-7) for funding and PIBIC for undergrad fellowship. Amanda dos Santos and Gabriel R. Magalhães.

**RP168 The effects of sea lice chemotherapeutants on non-target Pacific prawns (*Pandalus platyceros*)**

*J. Bennett, C.J. Kennedy, Simon Fraser University / Department of Biological Sciences*

To counter the challenges from diseases, parasites, and fouling organisms that can affect the health of cultivated species, the aquaculture industry utilizes a variety of regulated chemicals loosely categorized as disinfectants, antifoulants, and medicines. A number of compounds have been used, or are currently being used, to treat sea lice infestations in salmon aquaculture. There exists a notable lack of information specific to the toxicity of these chemotherapeutants to non-target species found on the Pacific coast of North America where salmon aquaculture is common. Standard prawn culture techniques were used to raise larval, post-larval, and juvenile stages of spot prawn. Acute bioassays were performed for the determination of various toxicological parameters (LC25, LC50, EC25, EC50 with 95% confidence limits). In these tests with 4 life stages (newly hatched, Stage III, and Stage V postlarval stage, and adults), exposures for all chemicals were 1, 2, and 3 h in duration. Prawns were exposed to the formulations Salmosan®, Paramove®50, and SLICE®*via*water. Adults were examined in sublethal exposures for various alterations in physiology and behaviour. Data for 3 developmental stages (larval stages I, III, and V) of the spot prawn indicate that these early life stages are far more sensitive to all chemotherapeutants compared to adults. Salmosan®and SLICE®are more acutely toxic than Paramove®50, and there is some variability in sensitivity between developmental stages. Prawnsactively avoided SLICE®, Salmosan®, and Paramove®50 at various concentrations. Exposure of adults to these formulations resulted in increased oxygen consumption and several changes in locomotory and food-related behaviours. The data obtained from this project is required to ensure the proper and safe use, and appropriate regulation of these aquaculture chemicals in coastal ecosystems.

**RP169 Tools for Analyzing Concentration-Response Data: A Comparative Assessment for Supporting EPA Aquatic Life Water Quality Criteria Derivation**

*J. Justice, USEPA; K. Gallagher, USEPA / Office of Water; B. Schnikter, USEPA; M. Elias, C. Bergeron, USEPA / Office of Water*

Derivation of Clean Water Act Section 304(a) Ambient Water Quality Criteria for the protection of aquatic life typically rely on empirical, laboratory-based aquatic toxicity values. Acute toxicity values are represented as $LC_{50}$ values. Chronic toxicity values were historically based on no-or-low observed effect concentrations (NOEC, LOEC) determined through hypothesis-based testing; however, recent aquatic life criteria documents have preferentially relied on chronic toxicity values determined as point estimates (e.g., $EC_{20}$), due to inherent limitations in hypothesis-based testing. For example, effect concentrations determined from hypothesis-based testing are heavily influenced by the concentrations tested, which limits consideration of concentration-response relationships. Therefore, the ability to generate, interpret, and select the most representative and reliable statistical fits from concentration-response (C-R) data is increasingly important for determining robust acute and chronic effect concentrations (i.e., $LC_X$, $EC_X$). EPA's Toxicity Response Analysis Program (TRAP) has routinely been used to support effects assessments and Aquatic Life Water Quality Criteria; however, alternative curve-fitting programs, including EPA's Benchmark Dose Software (BMDS) and R software, may provide additional models and guidance for fitting and interpreting C-R data. The goal of this research is to evaluate the use of TRAP, BMDS, and R for estimating acute and chronic effect concentrations across a range of pollutants, taxa, and effect levels. This assessment comparatively asses model output across curve-fitting programs and provides a framework for selecting and documenting appropriate C-R models to estimate effect concentrations and support the derivation of Aquatic Life Water Quality Criteria

**RP170 Toxicity effects of polyhalogenated carbazole compounds to a model organism the nematode *C. elegans***

*S.V. Sambukumar, K.A. Lenz, H. Ma, University of Wisconsin, Milwaukee / Zilber School of Public Health*

Polyhalogenated carbazoles (PHCZs) have been widely detected in river deposits and lake sediments across North America Great Lakes during the past two decades. The structural similarity of these PHCZs with halogenated dibenzofuran derivatives raises concerns about their potential dioxin-like toxicity. Here we investigated toxicity of five PHCZs (carbazole(CZ); 2,7-dibromocarbazole (27-DBCZ); 3,6-dibromocarbzaole (36-DBCZ); 3,6-dichlorocarbazole (36-DCCZ); 1,3,6,8-tetrabromocarbazole (1368-TBCZ)) to a model organism the nematode *C. elegans.* 2,3,7,8-TCDD was also included in the study for comparisons. Apical toxicity endpoints included lethality, reproduction, and lifespan. Germline toxicity was evaluated using a *xol-1::GFP* transgenic strain. Impact on gene expression at sublethal concentrations was examined for groups of genes involved in heat-shock response (*hsp 16.1, hsp 16.2, hsp 16.48, hsp 70*), oxidative stress (*sod1~5, ctl1~3, daf-2, daf-16, gcs-1, gst-4, skn-1*), xenobiotic metabolism (*cyp-35a1~5*) and development (*vit-2, vit-5~6*). Acute toxicity (24-h LC50) showed the following trend: 27-DBCZ(0.15µM) > 36-DCCZ(0.44 µM) > 36-DBCZ(2.05 µM) ≈ 2378-TCDD(3.2 µM) > 1368-TBCZ(10.3 µM) ≈ CZ(12.1 µM), with 27-DBCZ being the most toxic and CZ the least toxic. Impact on worm reproduction occurred at concentrations one order of magnitude lower than LC50s and was concentration dependent. Impact on lifespan showed similar patterns as reproduction, with 27-DBCZ, 36-DCCZ, and 36-DBCZ showing greater impact than others. All five PHCZs and TCDD showed germline toxicity as indicated by "green eggs". Impact on gene expression depended on the chemicals as well as the genes examined. Significant upregulation (fold-change of 4~6) of *hsp* genes was only observed for 27-DBCZ. Downregulation (fold-change of 3~4) of *vit* genes was only seen for CZ. Among all the oxidative stress related genes examined, only *sod-3* showed slight downregulation for 27-DBC, 36-DBC, 36-DCC, and 1368-TBC (fold-change of 2~4), and *sod-5* showed upregulation for CZ and TCDD (fold-change of 4~5). For xenobiotic metabolism related genes, 1368-TBC induced significant upregulation in all five *cyp-35a* genes (fold-change of 14~466). Our findings suggest these PHCZs induce systemic toxicity effects in the worm, and the toxicity is dependent on the chemical. Impact on *cyp35a* genes warrants further investigations as it may shed light on understanding the mechanisms of toxicity for these PHCZs as compared to TCDD.

# Assessing the Risk of Complex Mixtures: Advances and Challenges

### PC001 Substance mapping: A first step towards developing a better assessment strategy for UVCBs

*S.E. Deglin, ILSI Health and Environmental Sciences Institute (HESI); M. Fernandez, Environment Canada / Ecological Assessment Division; J. Arey, ExxonMobil Biomedical Sciences Inc; M.R. Embry, Health and Environmental Sciences Institute (HESI); K. Jenner, Givaudan / Global Regulatory Affairs & Product Safety; J. de Knecht, RIVM / Environment Health and Safety Division; M. Lampi, ExxonMobil Biomedical Sciences, Inc. / Toxicology & Environmental Sciences; P. Leonards, VU University, Institute for Environmental Studies / Department of Environment and Health; D. Lyon, Shell Oil Co. / Shell Health Risk Science Team; M. MacLeod, Stockholm University / Department of Environmental Science and Analytical Chemistry; P. Mayer, Technical University of Denmark / Department of Environmental Engineering; D.T. Salvito, Research Institute for Fragrance Materials, Inc. / Department of Environmental Science*

Risk assessment of complex substances (e.g., multi-constituent substances (MCs), and substances of Unknown or Variable Composition, Complex Reaction Products, and Biological Materials (UVCBs)) presents numerous challenges. International regulatory programs (specifically REACH, Canada's Chemicals Management Plan, and USEPA's PMN process) have highlighted the complexities of characterizing fate and exposure, risk assessment, and registration of these types of substances. A new HESI Project Committee was started in early 2018, with the goal of developing a tiered approach to assess ecological risks of MCs / UVCBs, and meet regulatory needs. The Committee determined that mapping the vast and complex universe of UVCB substances by chemical and/or functional classes should be the foundation of all work performed on this project, as a key to better understand the nature of these substances and their sector of use, and provide insight on which of them present the largest regulatory challenges. This exercise will also help identify UVCBs of most concern to the environment and human health. The classification of UVCBs according to criteria such as chemistry similarities and use patterns could ultimately help the development of strategies and streamline the risk assessment of these substances. Examples of UVCB mapping by participating regulatory agencies will be presented and some of the most common categories of UVCBs will be highlighted along with the technical challenges associated with risk assessment of these classes. Depending on the identified classes of UVCBs, it may be possible to apply many of the existing analytical and assessment methods to characterize UVCBs and evaluate their hazard potential. An important starting point, however, is to have the most accurate information to identify and characterize the MCs and UVCBs to ensure that their chemical classification is accurate. [*The views of the authors of this presentation are those of the authors and do not represent the views of their respective organizations*]

### PC002 Considerations for Measuring Exposure to Chemical Mixtures

*L. Paulik, Maul Foster & Alongi, Inc. / Environmental and Molecular Toxicology; K.A. Anderson, Oregon State University / Environmental and Molecular Toxicology*

Exposure to chemical mixtures contributes to human disease risk. Analytical capability is continuing to increase, but the toxicities and environmental occurrences of many chemicals remain understudied. If a commercial chemical standard does not exist for a given chemical, then little to no quantitative data likely exists for that chemical. This presentation will provide the highlights from a chapter in *Chemical Mixtures and Combined Chemical and Nonchemical Stressors*, a book that was published in winter of 2018. This presentation will discuss exposures to organic chemical mixtures, necessary considerations for studying those exposures, and research needs to continue to advance the field of mixtures exposure science. When planning or reviewing studies that focus on exposure to chemical mixtures, important considerations include: spatial orientation of sampling, temporality of sampling, bioavailability of measured chemicals, measuring enough of the appropriate chemicals, potential for chemical transformations, and mixture effects. This presentation will also use case studies to illustrate how these considerations can be applied when designing a study or interpreting results from a study. The case studies focus on assessing the potential for emissions from natural gas extraction (NGE) to affect polycyclic aromatic hydrocarbon (PAH) exposures of people a) eating food crops grown near active NGE wells, and b) living or working near active NGE wells. Importantly, relatively little is known about how exposure to chemical mixtures differs from exposure to individual chemicals. Most toxicity studies are performed using individual chemicals and nearly all exposures involve chemical mixtures. Characterizing the toxicity of chemical mixtures should therefore be a priority for the scientific community.

### PC003 Bioconcentration factors of constituents of pine oil in fish determined in an in-vivo benchmarked dietary exposure study

*M. MacLeod, C.L. Chen, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES*

Essential oils are fragrance materials that are registered as natural complex substances (NCS) under the European REACH legislation. One of the categories of information required in a REACH registration is information about the potential for bioaccumulation of NCS by fish. Determining the bioconcentration factor (BCF) of essential oils cannot be readily accomplished using a standard flow-through uptake/depuration experiment. Previously, we demonstrated that a single dietary exposure coupled to the benchmarking technique could be applied to an artificial mixture for measuring the in vivo BCF. Here, we report an application of our proposed BCF-determination methodology on a real essential oil – pine oil. Fish (rainbow trout) were dosed with a mixture of the pine oil and a suite of benchmark chemicals via a single dietary exposure. The depuration rate constants ($k_T$) in the fish soma (without GIT) for the key pine oil constituents are 0.134 $d^{-1}$ (β-Caryophyllene, BCP) – 1.41 $d^{-1}$ (BAc) and they were 0.0.0799 $d^{-1}$ (HCB) – 0.517 $d^{-1}$ (DiCB) for the reference chemicals. The test compounds depurated faster from the soma than the GIT, making estimated whole body depuration slower (conservative) compared to the soma only. HCB was the chemical most resistant to depuration among all the test compounds. Benchmarking to HCB reduced the standard error of measured $k_{T\text{-}BM}$ from the soma for most of the chemicals, with $k_{T\text{-}BM}$ ranging from 0.001 $d^{-1}$ (PCB52) to 2.98 $d^{-1}$ (BAc). The apparent BCF ($BCF_A$) values in soma for the key components in pine oil and the reference chemicals were in the range of 98.2 L $kg^{-1}$ (BAc) – 1030 L $kg^{-1}$ (BCP) and 267 L $kg^{-1}$ (DiCB) – 1730 L $kg^{-1}$ (HCB), respectively; while for the benchmarked BCF ($BCF_{BM}$) in soma, they are 46.3 L $kg^{-1}$ (BAc) – 2050 L $kg^{-1}$ (BCP), and 208 L $kg^{-1}$ (DiCB) – 197000 L $kg^{-1}$ (PCB52) repectively. We conclude that a single dietary expourse coupled with the benchmarking technique is a feasible experimental approach for measuring the BCF of NCS in fish.

### PC004 Threshold of Toxicological Concern risk assessment for a mixture of chlorinated aromatic sulfonic acid chemicals through drinking water exposure

*E. Neuwirth, DTSC / Department of Toxic Substances Control*

Threshold of Toxicological Concern (TTC) risk assessments are used by some regulatory agencies as tools for determining levels of exposure to chemicals of undetermined toxicity below which there is minimal concern and for prioritizing additional evaluation where TTCs are exceeded. Effluent from a treatment system for groundwater at a hazardous waste landfill contains a mixture of polar chlorinated aromatic sulfonic acid compounds that are byproducts of historical DDT production and which are not removed by treatments systems designed to remove other contaminants. A contract laboratory utilized liquid chromatography and electrospray ionization tandem mass spectrometry to tentatively identify and estimate the concentrations of the constituent compounds in the undiluted effluent. Since chemical specific toxicological information is unavailable, a TTC risk assessment was performed. TTC classification was performed using the software, Toxtree. In addition, other publically available in silico tools were utilized to support the TTC classification. Drinking water equivalent levels (DWELs) for the TTCs were calculated using California Office of Environmental Health Hazard Assessment (OEHHA) age-specific drinking water ingestion rates. TTC DWELs can be used by the publically owned treatment works that ultimately receives the effluent to determine needed analytical reporting limits as well determine the need for additional risk evaluation or management. The TTC risk assessment will be presented.

**PC005 Application of two frameworks for estimating mixture toxicity of fish contaminants**

*N. Urban, J.A. Perlinger, Michigan Technological University / Civil and Environmental Engineering; E. Shaw, Michigan Technological University*

Historically, fish consumption advisories (FCAs) have been based on the most sensitive endpoint (lowest reference dose) for single contaminants. Given that there are always multiple contaminants present in fish, that some contaminants may share common health effect end points, and that many contaminants influence the uptake or clearance or degradation of other contaminants, this single contaminant approach may inadequately assess the risk of fish consumption. Given that synergistic effects among contaminants are seldom observed and that we do not yet know many of the contaminant interactions that do occur, it has been argued that chemical additivity (CA) is an appropriate model for estimating total risk. In this study, we apply the CA model in two ways to estimate cumulative toxicity in fish to answer three questions: 1) What are the major contributors to the total toxicity of dioxin-like compounds (DLC) in fish? 2) What are the relative contributions of the two dominant fish contaminants (mercury, PCBs) to cumulative toxicity? And 3) What is the variability in cumulative toxicity relative to that due to single contaminants? We utilize two data sets for this analysis: Michigan's Fish Contaminant Monitoring Program and EPA's National Fish Tissue Survey. Within the Michigan data set, two PCB congeners accounted for the majority of the DLC; in all fish, PCB contributions to the total toxic equivalents exceeded that of dioxins and furans. Mercury and PCBs were observed to accumulate in different types of lakes; mercury was dominant in small, inland lakes and PCBs were dominant in larger lakes including the Great Lakes. As a result, the variance in total toxicity was less than the variance for the individual contaminants.

**PC006 ITRC TPH Risk Assessment Guidance Document**

*A. Goldberg Day, ARCADIS*

Background. Total petroleum hydrocarbons (TPH) mixtures are not always evaluated in human health or ecological risk assessments. Instead a somewhat arbitrary 100 parts per million is often applied as a cleanup goal. To address the lack of TPH criteria, TPH is often evaluated using surrogate chemicals such as benzene, naphthalene, and ethylbenzene. To address the lack of TPH risk assessment guidance, the Interstate Technology Regulatory Council (ITRC) will be publishing a TPH Risk Assessment guidance document, due to be released in November 2018. ITRC Guidance Document. The objective of this guidance is to build on previously published research to assist users in evaluating potential risks and risk-based corrective action assessments at petroleum hydrocarbon spill and release sites. In general, this guidance will present the current science and understanding of TPH risk characterization. The document will present why TPH risk characterization is important and provide a resource to guide users in making technically defensible assessments at TPH impacted sites to protect human and environmental health. The document will also describe the unique issues that should be addressed when characterizing TPH risks. Applicability and limitations of this will also be presented. Presentation. This presentation will discuss the methods for performing both human health and ecological risk assessment. This includes providing information the physico-chemical properties that determine the behavior of petroleum hydrocarbons in the environment and the various analytical methods available. Sampling strategies for both human health and ecological evaluations will be included. The ITRC TPH document will also identify the tool gaps for evaluating human health and ecological risk for TPH. Where appropriate, advice will be provided on how to address these gaps so that risk-based conclusions can be as complete as possible and the resulting risk information effective in terms of supporting risk management decisions. A demonstration of the on-line tool will also be included.

**PC007 Developing a strategy to improve the environmental risk assessment of substances of unknown and variable composition (MCS/ UVCB)**

*D.T. Salvito, Research Institute for Fragrance Materials (RIFM) / Dept of Environmental Science; J. Arey, ExxonMobil Biomedical Sciences Inc; S.E. Deglin, M.R. Embry, Health and Environmental Sciences Institute (HESI); K. Jenner, Givaudan / Global Regulatory Affairs & Product Safety; J. de Knecht, RIVM / Environment Health and Safety Division; M. Lampi, ExxonMobil Biomedical Sciences, Inc. / Toxicology & Environmental Sciences; P. Leonards, VU University, Institute for Environmental Studies / Department of Environment and Health; D. Lyon, Shell Oil Co. / Shell Health Risk Science Team; M. MacLeod, Stockholm University / Department of Environmental Science and Analytical Chemistry; P. Mayer, Technical University of Denmark / Department of Environmental Engineering*

The complexity of Multi-Constituent Substances (MCS) and Substances of Unknown or Variable Composition, Complex Reaction Products, and Biological Materials (UVCBs) pose a unique challenge to regulators and to product registrants having to characterize their fate, exposure, hazard, and potential risks to human health and the environment. International regulatory frameworks (specifically REACH, Canada's DSL Categorization and Chemicals Management Plan, and USEPA's PMN process) have highlighted the difficulties of registering these products. A new HESI Project Committee was started in early 2018, with the goal of developing a tiered approach to assess ecological risks of MCS / UVCB to address scientific and regulatory needs. Through the engagement of stakeholders facing challenges associated with these substances, this Committee will foster the exchange of knowledge about MCS / UVCB, and develop and optimize a cross-sectorial approach for the classification, identification, characterization and assessment of these substances. In first step, the Committee focused on the mapping of the vast and complex universe of UVCB substances to provide a foundation for subsequent work, and better understand the nature of these substances and their sector(s) of use. It will also provide insight on which groups of substances present the largest regulatory challenges and where strategic approaches for assessment would be most valuable. The outcome of the mapping exercise will also inform how to apply existing analytical assessment methods such as read-across, QSAR and trend analysis to characterize UVCBs and evaluate their potential hazard. It may also allow for the identification of analytical gaps and inform the development of new UVCB identification and characterization methods. Finally, part of this effort will be devoted to the review and evaluation of existing sector-specific MCS / UVCB assessment tools with an aim towards making them more widely applicable to other substances and/or to develop new assessment tools and methods that apply to other substance groups. Ultimately, this project will lead to the development of best practices to appropriately evaluate the environmental fate, and assess the ecotoxicity of MCSs / UVCBs.

## Endocrine Disruption in Invertebrates: Historical Perspectives, New Developments and Key Research Needs

**PC008 Endocrine disrupting effects of organic ultraviolet-filters on *Daphnia magna* molting and development**

*F. Lambert, University of Florida / Center for Environmental and Human Toxicology; C. Vulpe, University of Florida / Department of Physiological Science and the Center for Environmental and Human Toxicology*

Organic Ultraviolet-filters (UV-Fs) are emerging contaminants of concern and ubiquitously found in the aquatic environment. Many organic UV-Fs are endocrine disrupting compounds (EDCs) in vertebrates. However, only a handful of studies have assessed their potential to cause endocrine disruption in invertebrate species. The process of molting, or the shedding of the exoskeleton in arthropods, has been a suggested target of these compounds. Molting is necessary for growth and development and is regulated by an arthropod-specific endocrine system, the ecdysteroid pathway. Alterations of this process by EDCs can result in improper development, reduced growth, or death, resulting in potentially significant implications for organism and population health. In this study we investigate the hormonal activity of organic UV-Fs in a crustacean. *Daphnia magna* are chronically exposed to three common organic UV-Fs: 4-methylbenzylidene (4MB3), octylmethoxycinnamate (OMC), and benzophenone-3 (BP3) and assessed for alterations in normal molting and development. Additionally, changes in expression of the ecdysteroid regulated genes *EcRA, EcRB, HR3,* and *E75* are evaluated upon acute exposure to 4MBC, OMC, and BP3. This study is the first to assess the ability of UV-Fs to act as endocrine disruptors of ecdysteroid regulated processes in a crustacean.

**PC009 Bioaccumulation of 4-nonylphenol in blue crab, *Callinectes sapidus*, juveniles does not affect growth but exponentially increases hsp90 expression**

*S. Chiasson, Loyola University / EEB; C.M. Taylor, Tulane University / Ecology & Evolutionary Biology*

Endocrine disrupting chemicals (EDCs) enter the environment from anthropogenic sources, and some of these chemicals have estrogen mimicking properties. In our previous study 4-nonylphenol (NP) was detected in post-larval blue crabs, *Callinectes sapidus* at concentrations that exceeded the No Observed Effect Concentration for aquatic invertebrates. The blue crab, *Callinectes sapidus*, is an ecologically and economically important invertebrate that lives in coastal estuaries. In this study, juvenile blue crabs were exposed to seven sub-lethal (0 – 200 ppm) concentrations of NP, and accumulation was measured in crabs after a 24-hour exposure using GC/MS. Also, mRNA expression of genes encoding heat shock protein 90 (*hsp90*) and vitellogenin (*vtg*) were measured in crab hepatopancreas tissue. Crabs were found to linearly accumulate NP, whereas expression of *hsp90* in the hepatopancreas increased exponentially with NP concentration. To test for effects on juvenile blue crab growth at environmentally relevant concentrations, crabs were exposed to NP and monitored in tanks for one molt cycle. Expression of *vtg* was not affected by exposure to NP, and no significant differences were detected in growth or intermolt duration. This study shows that bioaccumulation of NP does not appear to affect growth at the measured sub-lethal concentrations whereas *hsp90* expression increased exponentially, linking NP exposure to two different endpoints.

**PC010 Atypical Length Responses in Mysid Chronic Testing – Are They Relevant to Risk Assessment**

*L. Sayers, R.C. Biever, Smithers Viscient / Department of Ecotoxicology*

Invertebrate life cycle exposures are a key element to the requirements for many regulatory bodies for risk assessment. Mysid shrimp (*Americamysis bahia*), a marine invertebrate, are a relevant species for this evaluation as they are potential indicators of effects test chemicals on aquatic invertebrates. In the United States, several documents exist to provide guidance on developing data for the chronic exposure of chemicals to mysid shrimp (USEPA, ASTM) however European requirements (i.e. REACH) have no specific requirements for marine species. Thirty mysid chronic studies were evaluated, seven of which were conducted utilizing a co-solvent. These exposures were conducted between 2013 and 2017. In review of the length data associated with these studies, an interesting trend appears. For length in particular, 40% of the data sets contain results where all treatment values are less than the control for male mysid and 30% of all treatment values are less than the control for female mysid. This pattern might be expected for a traditional ecotoxicology dose response however, additional data sets occur where all lengths for treated male and female mysid are all greater than the controls (10% and 17% of the data sets, respectively). The obvious prevalence of data sets where results for the treatments are, in their entirety, either greater than the control or less than the control speaks to a trend that may need to be considered in the interpretation of a toxicant related effect (either enhancement or suppression). This talk will explore these data sets with an eye towards biological relevance in the risk assessment setting and current guidance on biological relevance (EFSA, 2017). In the case of either complete suppression or enhancement, it is reasonable to conclude that there is some cause for this response even if the response is not significantly different from the control or from historical control values. However, if this response does not have an effect on a population level (i.e. reproduction is not impacted) or a corroborating effect in the weight endpoint, these effects may not be relevant in the risk assessment setting.

**PC011 Intersexuality in Aquatic Invertebrates: Prevalence, Causes, Toxicological Mechanisms and Research Directions**

*T. Grilo, R. Rosa, MARE – Marine and Environmental Sciences Centre*

This study intends to assemble information on intersexuality in aquatic invertebrates, from freshwater to estuarine andmarine environments. Intersex is a condition whereby an individual of a gonochorist (separate sexes) species has oocytes or distinct stages of spermatogonia, at varying degrees of development, within the normal gonad of the opposite gender (i.e. spermatocytes in the ovary or oocytes in the testis), often involving alterations in the gonadal structure, reproductive tract or external genitalia. By the end of 2016 we found approximately 340 records of aquatic invertebrate species evidencing signs of intersexuality (or imposex), all comprised within the Phyla Mollusca and Arthropoda. Gastropod molluscs are by far the group with more examples documented (256 species), followed by crustaceans, i.e., decapods, copepods and amphipods. To our knowledge no further cases of intersexuality were known concerning other invertebrate taxa. Despite some reports suggesting that a baseline level of intersexuality may occur naturally in some populations, the causes are multifaceted and mostly linked with environmental contamination by estrogenic and organotin endocrine disrupting chemicals (EDCs), parasitism, and genetic/environmental sex determination abnormalities. A more comprehensive discussion about the origin of intersexuality, prevalence and causes, knowledge gaps and future research directions in the light of new omics scientific advances (genomics, proteomics and transcriptomics) is also provided. The lack of studies linking molecular responses of invertebrate intersex individuals to multiple stressors represents a true challenge to be further investigated in the future.

## Ecological, Human Health, Economic and Social Impacts of Wildland Fires

### PC012 Setting the Stage: Ecological, Human Health, Economic and Social Impacts of Wildland Fires

*C. Baghdikian, USEPA / Office of Research and Development / National Health and Environmental Effects Research Laboratory*

Fire is vital to maintaining ecosystem functioning, however there are tradeoffs. Increasing wildland fires pose direct risks to human health and ecosystem services--air quality, clean water. More people are living in high risk areas, often referred to as the Wildland-Urban Interface (WUI), resulting in increasing risks from smoke exposure, and higher risk to life and property. Further, fire-prone ecosystems, forests in most cases, are sources of our national water supply—wildland fires can result in water quality degradation from sediment and nutrient transport, as well as decreased storage capacity in damaged watersheds. This presentation will set the stage for the rest of the session, where you will hear from experts across the landscape of wildland fire research.

### PC013 The High Cost of Burning: Economic Costs of Wildland Fires and Smoke in the US

*B. Hubbell, USEPA / Office of Research and Development; D. Butry, NIST*

The prevalence and severity of wildfires has been increasing over the past decade due to both past fire management practices and changes in climate. At the same time, the wildland-urban interface has been increasing, which potentially increases the economic risks associated with wildfires. Economic costs arise directly from activities to control fires and protect populations (e.g. evacuations), the burning of structures and property, adverse impacts on watersheds and ecosystems, and also through property, environmental, and health impacts from exposures to smoke from wildland fires. These costs can occur in communities far distant from the location of the fires. Costs are also associated with increased fire management activities, including increased numbers of fire fighters and related costs, and increased costs to manage fuel loads and carry out prescribed and controlled burns. In addition, costs to insure at-risk property can be significant. This presentation will provide an overview of research on the economic costs from wildland fires, with a focus on costs associated with smoke exposures. Direct costs of wildfire suppression have been fairly well characterized, with estimates of $2 to $3 billion per year. Estimates of total costs of wildfires including both costs of suppression and value of wildfire related impacts (both beneficial and harmful) are more variable, but a recent estimate indicates total annualized net economic costs of $71.1 to $347.8 billion. The costs associated with smoke from wildland fires is a growing area of research. These smoke-related costs have the potential to be very substantial, given the potential for widespread exposures to wildfire smoke in heavily populated areas coupled with the strong evidence linking smoke and a range of health effects that includes symptoms such as eye irritation, sore throat, wheezing, and coughing worsening of respiratory diseases like asthma and chronic obstructive pulmonary disease, bronchitis, pneumonia, cardiovascular events, increased rates of cardiorespiratory emergency department (ED) visits, adverse birth outcomes, hospitalizations, and premature death. A recent study estimated that the annual economic burden of smoke related health effects over the period from 2008 to 2012 was nearly $100 billion. Additional costs related to smoke exposures, including impacts on livestock, structures, and ecosystems, have not been well characterized.

### PC014 Ecological Effects of Wildland Fire: Tradeoffs for Delivery of Ecosystem Services

*P. Beedlow, W.S. Fisher, USEPA / Office of Research and Development / National Health and Environmental Effects Research Laboratory*

Fire is a vital process for sustained ecosystem functioning, providing habitat vitality and renewal through recolonization of new populations and succession of fire-tolerant species. Twentieth century fire management practices have shown that removal of fire from fire-adapted ecosystems leads to catastrophic unintended fires, which are detrimental to both human health and ecosystem services. Because more people are living in high fire-risk areas, there are increased hazards for life and property. Moreover, fire-prone ecosystems, forests in most cases, are major sources of our national water supply, and catastrophic wildland fires reduce canopy, ground cover and soil cohesion, which decreases water storage capacity and can lead to water quality degradation from sediment, nutrients and toxic compounds eroding into waterbodies. Eliminating wildland fires is neither possible nor desirable, but there are ways to reduce risks to water resources and delivery of ecosystem services. For example, areas vulnerable to wildfire can be targeted for management actions such as fuel reduction and prescribed burning. To better manage the effects of natural, accidental and prescribed fires will require improved information and technology for predicting fires (spatial and temporal) and for gauging risks, as well as tools for education, communication and community planning.

### PC015 Human Health Impacts of Wildland Fire and Smoke

*W.E. Cascio, USEPA / NHEERL*

Wildland fire and smoke from these fires can impact public health. The annual acreage burned in the U.S. from wildfires has risen steadily since 1985, and the fire season has lengthened. Wildland fires impair air quality by producing massive quantities of particulate air pollutants and ozone precursors. Together particles and ozone exposures increase the risk of premature death and acute and chronic cardiovascular and respiratory morbidity among vulnerable individuals. Future wildfires are predicted to be larger, more severe and more frequent in some regions of the U.S and will contribute to an even greater proportion of the ambient air pollution, the disease burden and healthcare costs. While the projected magnitude of the public health impact of a changing environment on wildfire events is uncertain, it is clear that the proportion of the U.S. population vulnerable to the adverse health effects of wildland fire and its smoke is increasing. An aging population with chronic respiratory diseases and increasing obesity and diabetes that heralds more cardiovascular disease will increase the vulnerability of the population to the adverse effects of wildfire smoke and associated stressors. Additionally, physiological changes attendant to aging decrease the capacity of aged-adults to tolerate wildfire smoke, heat, humidity, evacuation and recovery. Expansion of our cities into the wildland-urban interface is also placing a greater proportion of the population in closer proximity to wildland fire emissions with its associated health risks. The public health community has an opportunity to contribute to the broader national effort to mitigate wildland fire risk by working closely with the healthcare community to facilitate adaptive responses to wildfires. Adaptation will increase the resilience of individuals and their communities and is anticipated to help mitigate the adverse health effects of wildland fire. *This abstract does not reflect USEPA policy.*

### PC016 Psychological and Human Behavioral Responses to Wildland Fire

*M. Brunson, Utah State University / Environment and Society*

Humans have both managed and feared fire for millennia. Public officials and society as a whole are generally aware that wildland fires are increasing in frequency, size, and cost across North America. Yet efforts to reduce the risk of catastrophic wildfire fall short of what is needed at both individual and community levels. At the individual scale, human perceptions of wildfire risk and risk-reduction strategies are influenced by a variety of factors including: resource availability, perceived self-efficacy, previous experience with natural hazards, perceptions of the risk-reduction strategy, generalized beliefs about nature and the society-environment relationship, generalized beliefs about hazards and risk, and local norms. Risk-reduction efforts often have undesirable side effects that may be more immediate than the hazard they're designed to reduce. At the community scale, economic and demographic factors as well as socio-political norms influence a community's resilience to wildfire as well as its capacity to undertake risk-reduction efforts. Understanding how these various factors interact, both within and across scales, can help policy makers craft more effective programs to help people and ecosystems recover after wildfire events as well as reduce the risk of future wildfires.

## Improving Approaches to Assess Risks to Threatened and Endangered Species from Chemical Exposure

### PC017 Use of USEPA Regulatory Models in a Refined Malathion Endangered Species Aquatic Exposure Assessment

*M.F. Winchell, H. Rathjens, Stone Environmental, Inc. / Environmental Systems Modeling; L. Padilla, Stone Environmental, Inc.; P. Whatling, FMC Corporation*

Recent Biological Evaluations and Biological Opinions concerning the effects of currently registered organophosphate insecticides on threatened and endangered species have adopted regulatory aquatic exposure models and scenarios to represent a wide range of species and habitat characteristics. The application and parameterization of these models to date has been largely at a screening level in terms of the conservativeness of assumptions and the spatial specificity of the exposure model inputs and predictions. The best nationally available spatial datasets provide the information necessary to improve the parameterization of regulatory aquatic exposure models such as the PRZM landscape and VVWM receiving water models, and their resulting exposure estimates. To evaluate the practical use of these models and datasets in a national scale endangered species assessment, 100 different species across a range of taxonomic families, occupying static and flowing habitat, were assessed. The static water modeling approach focused on independently evaluating yearly realizations of crop data to represent multiple cropping configurations surrounding small static water bodies. The proximity of crops to water refined the drift exposure and the distribution of soil types and weather refined the runoff potential. The flowing water modeling approach took advantage of the NHDPlus catchment network to determine contributing watershed areas for each distinct catchment within a species range. The NHDPlus network and associated flow length and flow velocity attributes determined the lag-times of pesticide loads contributing from upstream catchments, and determined the duration of chemical degradation. The flowing water modeling also considered multiple independent years of crop data to generate an ensemble of cropped area realizations in each NHDPlus catchment and upstream watershed. In both the static and flowing habitat modeling, historical pesticide use data was used to estimate the fraction of catchments receiving malathion applications for each crop group, which was varied for each of the five crop years modeled. This exposure modeling approach resulted in species-specific EEC distributions that could be further filtered according to habitat characteristics (flow rate, water body size), grouped according to contributing watershed characteristics, and mapped explicitly to locate regions within a species range that are likely to experience exposure levels of potential concern.

### PC018 Species monitoring with environmental DNA (eDNA): Sampling design considerations

*R.A. Erickson,C. Merkes, USGS / Upper Midwest Environmental Sciences Center; E.L. Mize, USFWS / Whitney Genetics Lab*

Natural resource managers require knowledge of species distributions in order to manage the species. Within ecotoxicology, this is especially important so that exposure can be estimated. However, rare, cryptic, or otherwise hard to detect species can be difficult to observe. This is especially true for threatened or endangered species and newly arriving invasive species. One tool to detect these species is environmental DNA (eDNA). eDNA-based methods sample water, air, soil, or other locations in the "environment" of the species of interest. These samples are then analyzed using molecular tools such as quantitative polymerase chain reaction (qPCR) or sequencing. An important consideration of eDNA-based sampling methods is imperfect detection. When sampling a location, a species may not be present all of the time. Within a site, a sample (e.g., water collection) may not contain eDNA by chance alone. Last, the molecular methods may have imperfect detection. Occurrence models are one method for accounting for these different levels of imperfect detection. These models can be used to estimate the probabilities of site occurrence, sample capture, and detection. Through the use of probability calculations and simulation, we compared different sample designs, with a focus on rare species (i.e., those with low detection and capture probabilities). We found detecting eDNA in ≥1 sample at a site required ≤15 samples per site for common species, but detecting eDNA when looking for rare species required 45-90 samples per site. Our occurrence model recovered known parameters unless capture and detection probabilities were < 0.2 where >100 samples per site and ≥8 molecular replicates were required. Our findings illustrate the importance of sample size and molecular replication for eDNA-based work.

### PC019 Beyond Population Modeling for Endangered Species Risk Assessment

*D. Preziosi, B. Sackmann, E. Mendelsohn, R.A. Pastorok, Integral Consulting, Inc.*

Population modeling is an essential tool for assessing pesticide risks to endangered species. But is modeling at the population level sufficient to protect rare species? We evaluate the role of ecosystem modeling in endangered species risk assessments, particularly with respect to potential indirect effects mediated via species interactions (e.g., trophic pathways). Inter-species interactions within the biological community in most ecosystem models focus on predator-prey (or grazer-resource) interactions and intra- and inter-species competition. We present examples of trophic cascades and address how ecosystem modeling can support endangered species risk assessments. Ecosystem modeling allows consideration of not only indirect effects but also other physical stressors such as habitat temperature modification associated with climate change or physical removal of habitat during human development. In certain cases, other interactions are added to such models; for example symbiotic relationships for coral-algal species and parasitoid-host relationships for agricultural settings where biological control is part of an integrated pest management system. We explore challenges in ecosystem modeling, including some specific to endangered species and also common to population modeling. With ecosystem models, the challenges are multiplied by the complexity of the food web being modeled. A framework for use of ecological models for endangered species should combine multi-modeling approaches; classification of endangered species by life history characteristics and vulnerability; and methods to estimate biological and ecological parameters of rare species from surrogate species data.

### PC020 Croplife America Ecological Risk Assessment Framework for Endangered Species Assessments

*S. Teed, Intrinsik Corp; T. Hall, Bayer / Environmental Toxicology and Risk Assessment; K. Henry, NovaSource / Tessenderlo Kerley, Inc. / Ecological Sciences; S. Mortensen, BASF Corporation; L.S. Ortego, Bayer CropScience / Environmental Toxicology and Risk Assessment; M.F. Winchell, Stone Environmental, Inc. / Environmental Systems Modeling; N. Snyder, Waterborne Environmental, Inc.; M.G. Dobbs, Bayer CropScience / Environmental Toxicology and Risk Assessment; N. Peranginangin, Syngenta Crop Protection, LLC / Product Safety; J. Collins, CropLife America*

Ensuring that populations of threatened and endangered species in the United States remain viable is an important factor in enhancing our environment and maintaining biodiversity. While habitat loss is often the primary risk to listed species, endangered species risk assessments (ESRA) can identify cases in which exposure to pesticides could potentially increase risk, in some situations. Pesticide registration and re-registration under Federal Insecticide, Fungicide and Rodenticide Act (FIFRA) administered by the Environmental Protection Agency (EPA) constitutes a federal action and thus is subject to review under Section 7 of the Endangered Species Act (ESA), administered by the Fish and Wildlife Service (FWS) and National Marine Fisheries Services (NMFS) (collectively called the Services). In the 2013 report entitled “Assessing Risks to Endangered and Threatened Species from Pesticides”, the National Academy of Sciences (NAS) provided guidance for conducting endangered species risk assessments (ESRA) under FIFRA with direct consideration of the ESA Section 7 requirement. The NAS panel recommended the use of refined approaches (e.g., probabilistic methods, population modeling) when conducting assessments. In response to the NAS panel report, EPA, the Services, and USDA released a summary of their implementation plan (often called the ‘Interagency Interim Approach’) that presented a common approach to ESRA. The Interagency Interim Approach was applied in the development of the recent organophosphate (OP) (malathion, chlorpyrifos, and diazinon) biological evaluations (BEs). Unfortunately, these BEs illustrated that the Interagency Interim Approach is inefficient (e.g., failing to remove many species that are clearly not at risk), does not follow a tiered approach, is not scientifically defensible, and will result in unacceptable delays in regulatory decisions and require large increases in Agency resources, all with uncertain benefit to listed species and their critical habitats. This presentation presents a framework for conducting efficient ESRA using a conservative but scientifically defensible and rational approach adapted from the National Academy of Science panel report recommendations, the Overview of the Ecological Risk Assessment Process in the Office of Pesticide Programs, the 1998 EPA Risk Assessment Framework, and lessons learned from the OP case studies.

Accumulation 8, 132, 136, 158, 159, 240, 246, 355, 373, 393, 623, MP007, MP084, MP086, MP174, MP198, RP057, RP181, TP006, TP032, TP047, TP135, TP148, TP150, TP153, TP211, WP012, WP023, WP253
Acute toxicity 13, 32, 65, 157, 159, 290, 295, 313, 324, 362, 364, 365, 401, 416, 417, 445, 452, 473, 500, 522, 555, 584, 588, 638, 642, 689, MP007, MP020, MP025, MP037, MP042, MP043, MP058, MP064, MP082, MP093, MP165, MP188, MP192, MP267, PC009, RP018, RP030, RP039, RP047, RP084, RP131, RP134, RP135, RP138, RP147, RP149, RP150, RP157, RP158, RP164, RP181, TP013, TP023, TP026, TP078, TP110, TP111, TP115, TP117, TP122, TP124, TP196, TP202, TP217, TP218, TP240, TP241, TP252, WP019, WP026, WP027, WP031, WP100, WP104, WP106, WP122, WP139, WP152, WP160, WP170, WP225
Adsorption 267, 431, RP102, RP117, TP053, TP265, WP059, WP070, WP193, WP247, WP258, WP263
Adverse Outcome Pathways 34, 38, 72, 83, 213, 214, 215, 239, 302, 319, 374, 375, 376, 378, 381, 459, 469, 476, 525, 531, 543, 552, 553, 591, MP027, MP029, MP032, MP042, MP065, RP124, TP090, TP105, TP109, TP166, WP105, WP115, WP121, WP137, WP168, WP170, WP176, WP190, WP192
Ammonia 156, 295, 500, MP221, MP254
Amphibians and Reptiles 46, 66, 159, 171, 252, 315, 361, 367, 368, 369, 371, 372, 566, 604, MP054, MP209, MP261, RP133, TP105, TP165, WP077, WP104, WP171, WP174, WP175, WP176, WP177, WP178, WP179, WP180, WP181, WP187, WP188
Animal Alternatives 100, 120, 207, 302, 333, 470, 473, 476, 589, 591, MP025, MP042, MP052, TP025, TP166, WP073, WP112, WP113, WP117, WP118, WP119, WP121, WP122, WP124, WP187
Antimicrobial 395, MP028, RP087, TP017, TP020, TP246, WP199
Aquatic toxicity 12, 25, 27, 28, 38, 45, 47, 48, 58, 60, 66, 67, 68, 72, 75, 77, 83, 101, 102, 104, 115, 122, 126, 131, 133, 153, 155, 156, 157, 169, 175, 177, 182, 192, 206, 210, 212, 213, 215, 216, 239, 241, 250, 256, 293, 299, 300, 301, 308, 310, 313, 315, 317, 329, 333, 376, 377, 378, 390, 416, 417, 431, 441, 442, 444, 446, 448, 449, 451, 455, 465, 467, 468, 470, 472, 477, 479, 480, 502, 503, 515, 532, 535, 540, 542, 544, 548, 551, 562, 563, 564, 568, 575, 579, 581, 582, 585, 586, 587, 592, 602, 603, 608, 612, 620, 621, 625, 626, 628, 629, 631, 636, 639, 641, 643, 670, 672, 673, 674, 686, 689, 697, MP004, MP013, MP016, MP017, MP018, MP019, MP020, MP039, MP043, MP046, MP049, MP053, MP054, MP056, MP058, MP059, MP063, MP082, MP083, MP085, MP093, MP118, MP136, MP146, MP147, MP165, MP167, MP180, MP184, MP185, MP187, MP188, MP189, MP192, MP208, MP210, MP246, PC008, PC009, PC010, RP003, RP005, RP007, RP010, RP020, RP034, RP035, RP038, RP046, RP051, RP053, RP055, RP078, RP082, RP084, RP085, RP086, RP087, RP091, RP092, RP112, RP115, RP116, RP119, RP120, RP121, RP125, RP127, RP128, RP129, RP130, RP132, RP133, RP135, RP136, RP137, RP140, RP143, RP144, RP145, RP147, RP148, RP150, RP152, RP155, RP157, RP158, RP160, RP161, RP166, RP167, RP168, RP169, RP170, RP179, TP020, TP024, TP039, TP074, TP091, TP093, TP102, TP103, TP104, TP105, TP107, TP113, TP114, TP118, TP124, TP126, TP128, TP133, TP141, TP144, TP164, TP166, TP172, TP178, TP182, TP184, TP185, TP186, TP188, TP203, TP212, TP214, TP217, TP218, TP220, TP222, TP224, TP226, TP229, TP230, TP231, TP232, TP235, TP236, TP237, TP238, TP241, TP242, TP243, TP244, TP247, TP250, TP252, TP253, TP254, TP256, TP258, TP259, WP005, WP007, WP027, WP031, WP032, WP037, WP040, WP068, WP077, WP100, WP103, WP106, WP108, WP111, WP112, WP113, WP114, WP116, WP120, WP122, WP136, WP145, WP148, WP151, WP152, WP162, WP163, WP165, WP166, WP177, WP185, WP200, WP201, WP208, WP210, WP213, WP214, WP215, WP219, WP222, WP223, WP224, WP235,
Atrazine 126, 209, RP032, RP140, RP145, TP141, TP229
Avian 39, 95, 106, 194, 195, 198, 199, 207, 258, 281, 282, 283, 284, 285, 286, 287, 595, 695, 700, MP007, MP149, MP169, MP171, MP174, MP175, MP176, MP199, MP263, RP025, RP031, RP032, RP033, TP001, TP002, TP004, TP007, TP008, TP009, TP013, TP078, TP174, TP199, WP099, WP215
Behavior 12, 27, 108, 135, 173, 194, 214, 282, 301, 343, 356, 362, 378, 389, 430, 451, 452, 472, 495, 552, 554, 565, 572, 604, 607, 611, MP006, MP010, MP267, PC016, RP029, RP073, RP074, RP122, RP124, RP147, RP148, RP149, RP157, TP102, TP119, TP132, WP088, WP105, WP124, WP125, WP166, WP174
Big data 24, 34, 37, 39, 40, 137, 233, 235, 237, 238, 298, 312, 313, 315, 316, 318, 319, 334, 375, 465, 692, MP063, MP064, MP088, MP250, TP089, TP168, WP118, WP230
Bioaccumulation 1, 2, 3, 5, 6, 7, 10, 73, 75, 76, 95, 107, 133, 134, 138, 154, 184, 221, 226, 230, 232, 241, 242, 256, 257, 260, 280, 281, 283, 287, 309, 325, 344, 350, 397, 420, 432, 437, 438, 479, 481, 482, 483, 484, 485, 491, 493, 501, 513, 523, 545, 566, 570, 631, 654, 657, 660, 675, MP003, MP004, MP032, MP045, MP054, MP055, MP071, MP088, MP090, MP094, MP095, MP096, MP097, MP102, MP143, MP148, MP150, MP158, MP169, MP172, MP173, MP181, MP195, MP196, MP197, MP200, MP208, MP236, MP238, MP248, MP260, PC003, RP002, RP038, RP040, RP042, RP044, RP065, RP095, RP097, RP106, RP107, RP111, RP141, RP142, RP149, RP163, RP177, RP179, RP181, TP002, TP003, TP004, TP008, TP024, TP028, TP029, TP031, TP033, TP036, TP055, TP088, TP122, TP127, TP129, TP137, TP152, TP154, TP157, TP161, TP162, TP174, TP192, TP193, TP205, TP206, TP216, TP219, TP226, TP236, TP248, TP257, TP262, TP263, WP004, WP005, WP018, WP019, WP028, WP053, WP055, WP057, WP059, WP073, WP074, WP079, WP080, WP082, WP095, WP096, WP098, WP135, WP157, WP171, WP172, WP183, WP209, WP212, WP214
Bioavailability 9, 10, 11, 14, 41, 43, 44, 45, 46, 48, 51, 52, 79, 129, 130, 131, 132, 134, 135, 145, 217, 259, 263, 306, 309, 374, 390, 396, 421, 435, 478, 479, 487, 489, 490, 491, 501, 507, 641, 662, 663, 664, 666, 668, MP083, MP084, MP085, MP086, MP087, MP092, MP096, MP182, MP183, MP216, MP227, MP228, MP237, MP238, MP239, MP265, MP267, PC002, RP008, RP054, RP062, RP063, RP066, RP070, RP176, TP015, TP021, TP074, TP162, TP188, TP219, WP029, WP054, WP057, WP135, WP184, WP212, WP213
Biocides 191, 274, 292, MP019, MP041, TP124
Bioconcentration 2, 4, 8, 77, 95, 212, 327, 368, MP195, MP197, PC003, RP050, RP181, TP045, WP078, WP081, WP105, WP147, WP183
Biodegradation 90, 201, 227, 264, 266, 268, 269, 270, 271, 539, 596, 632, MP045, MP203, MP226, MP259, RP156, TP084, TP086, WP143, WP246, WP248
Biomonitoring 11, 15, 23, 39, 54, 88, 109, 153, 154, 193, 212, 221, 232, 261, 280, 304, 312, 316, 327, 333, 345, 346, 348, 354, 363, 436, 448, 449, 473, 474, 482, 496, 506, 541, 542, 543, 544, 546, 547, 567, 569, 584, 585, 610, 631, 670, 695, 697, MP053, MP055, MP094, MP097, MP098, MP102, MP149, MP153, MP158, MP159, MP170, MP175, MP200, MP205, MP206, RP028, RP035, RP036, RP040, RP079, RP083, RP088, RP089, RP092, RP093, RP097, RP099, RP126, RP134, RP146, RP163, RP179, TP001, TP010, TP014, TP024, TP029, TP032, TP034, TP036, TP042, TP043, TP044, TP046, TP047, TP054, TP065, TP089, TP134, TP136, TP140, TP204, TP251, TP255, TP263, WP017, WP025, WP096, WP123, WP145, WP220, WP226, WP256
Bioremediation 138, 172, 469, MP045, MP077, MP148, RP002, RP044, RP079, WP015, WP182, WP217, WP246, WP254
Biotransformation 147, 218, 220, 266, 434, 475, 504, 549, 550, MP190, MP198, MP259, RP072, RP101, RP152, TP024, TP085, TP086, TP101, TP226, TP260, WP072, WP073, WP074, WP075, WP078, WP082, WP182
Case study 18, 33, 35, 40, 58, 62, 63, 88, 90, 117, 119, 225, 246, 261, 264, 288, 289, 291, 338, 352, 399, 403, 404, 423, 426, 428, 448, 449, 509, 514, 515, 558, 574, 581, 596, 621, 622, 662, 670, 682, MP076, MP080, MP104, MP119, MP147, MP180, MP260, PC002, RP055, RP066, RP092, RP171, RP176, TP013, TP053, TP069, TP078, TP136, TP149, TP152, TP180, TP184, TP198, TP209, TP235, WP014, WP021, WP035, WP049, WP051, WP084, WP141, WP142, WP191, WP237, WP250
Chemical Alternatives 186, 187, 191, 291, 294, 645, MP071, MP073, MP203, WP084, WP086, WP087
Chemical signalling 68, 448, 471, MP140, TP052, TP163, WP121
Chronic toxicity 157, 158, 175, 215, 357, 368, 394, 462, 469, 478, 564, 586, 600, 642, MP020, MP047, MP081, MP083, MP088, MP089, MP153, MP154, MP242, MP256, MP266, RP001, RP019, RP051, RP060, RP085, RP086, RP087, RP100, RP127, RP137, RP138, RP165, TP054, TP093, TP113, TP116, TP120, TP130, TP131, TP135, TP176, TP215, TP233, TP259, WP006, WP017, WP026, WP038, WP104, WP122, WP136, WP151, WP152, WP213, WP216, WP219
Climate 25, 59, 82, 84, 161, 164, 167, 168, 240, 241, 242, 282, 386, 687, 688, MP033, MP035, MP041, MP192, MP252, TP036, TP065, TP071, TP143, WP095, WP131
Cytotoxicity 65, 99, 286, 381, 571, MP027, MP031, MP142, MP152, MP209, MP267, RP048, RP151, TP066, TP202, WP116, WP121, WP177
Decision analysis 62, 82, 207, 337, 339, 384, 684, MP033, MP034, MP073, PC013, RP013, RP155, TP136, TP161, WP119, WP237
Degradation 80, 92, 141, 190, 265, 267, 355, MP207, RP102, RP171, TP086, TP095, TP109, TP173, WP061, WP212, WP232, WP260, WP262, WP264
Depuration 499, MP090, TP021, TP108
Desorption 436, 652, MP099, MP109, MP132, MP238
Development 20, 122, 155, 159, 213, 235, 293, 317, 320, 322, 370, 439, 444, 472, 500, 555, 572, 611, 625, MP010, MP039, MP058, MP132, MP139, MP166, MP185, MP215, MP242, RP124, RP153, RP158, RP180, TP012, TP014, TP128, TP141, TP168, WP094, WP101, WP102, WP103, WP138, WP156, WP157, WP162, WP194, WP197, WP207, WP210, WP252
Dioxins 330, 400, 554, MP105, MP149, MP150, MP176, MP199, TP098, TP108, WP176, WP184, WP264
Ecological risk assessment 2, 3, 7, 15, 23, 25, 30, 36, 37, 40, 46, 83, 84, 86, 97, 98, 99, 102, 104, 106, 108, 109, 114, 115, 116, 118, 143, 150, 151, 152, 174, 185, 187, 188, 189, 190, 191, 197, 202, 205, 248, 249, 250, 251, 252, 253, 254, 255, 259, 263, 272, 273, 285, 302, 303, 306, 359, 363, 366, 369, 391, 397, 424, 428, 454, 455, 456, 457, 458, 460, 461, 476, 525, 528, 529, 530, 531, 532, 536, 537, 547, 550, 552, 553, 559, 561, 569, 573, 574, 589, 594, 595, 615, 618, 619, 631, 634, 635, 668, 690, 694, 696, 699, MP024, MP026, MP030, MP046, MP066, MP067, MP078, MP173, MP180, MP192, MP195, MP216, MP240, MP244, MP246, PC001, PC006, PC007, PC010, PC014, PC017, PC018, PC019, RP009, RP013, RP027,

Toxicokinetics 230, 308, 525, 672, 695, MP091, MP142, RP050, RP054, TP006, TP107, TP108, WP002, WP004, WP072, WP073, WP075, WP076, WP077, WP078, WP079, WP081, WP112, WP147, WP180, WP181

Uncertainty 7, 25, 104, 113, 206, 226, 238, 248, 424, 453, 454, 517, 552, 555, 594, 683, MP069, MP103, MP205, RP155, TP039, TP052, TP114, TP176, WP078

Urban 198, 272, 273, 275, 276, 278, 279, 297, 331, 332, 335, 343, 401, 415, 417, 467, 503, 506, 508, 639, 648, 677, MP050, MP092, MP101, MP102, MP103, RP001, RP058, TP048, TP070, TP082, TP099, TP192, TP227, TP254, WP014, WP024, WP042, WP062, WP067, WP069, WP092, WP097, WP106, WP140, WP141, WP204, WP205, WP206

Waste water 5, 31, 53, 92, 137, 139, 148, 162, 166, 179, 266, 289, 296, 297, 298, 318, 328, 335, 336, 365, 411, 412, 413, 433, 466, 473, 485, 495, 498, 504, 507, 541, 562, 581, 582, 583, 584, 630, 632, 649, 650, 651, 682, MP021, MP023, MP040, MP047, MP050, MP079, MP092, MP112, MP113, MP114, MP115, MP116, MP118, MP119, MP219, MP243, MP249, RP007, RP024, RP049, RP057, RP142, RP162, TP087, TP094, TP095, TP096, TP097, TP100, TP113, TP115, TP116, TP196, TP201, TP230, TP244, TP246, TP250, WP012, WP016, WP024, WP043, WP056, WP067, WP093, WP094, WP126, WP133, WP143, WP153, WP175, WP238

Water quality 15, 22, 23, 29, 30, 41, 42, 45, 49, 58, 60, 73, 94, 117, 129, 146, 149, 151, 162, 165, 170, 204, 222, 228, 237, 247, 256, 257, 260, 262, 272, 277, 279, 296, 310, 329, 382, 390, 391, 392, 396, 406, 407, 408, 411, 412, 413, 414, 415, 464, 480, 481, 496, 499, 502, 515, 534, 538, 557, 558, 560, 588, 637, 651, 653, 654, 655, 659, 669, 671, 676, 685, 690, 694, MP008, MP021, MP031, MP040, MP068, MP085, MP094, MP117, MP119, MP120, MP127, MP147, MP163, MP188, MP201, MP215, MP221, MP225, MP231, PC004, PC012, PC014, PC017, RP001, RP008, RP017, RP034, RP049, RP080, RP085, RP093, RP098, RP101, RP102, RP118, RP169, TP039, TP057, TP058, TP079, TP081, TP100, TP109, TP110, TP111, TP134, TP138, TP140, TP148, TP159, TP167, TP169, TP185, TP187, TP190, TP195, TP206, TP213, TP215, TP225, TP239, TP245, TP249, TP252, TP255, TP259, TP261, TP264, WP025, WP027, WP030, WP032, WP042, WP061, WP065, WP110, WP155, WP194, WP196, WP197, WP198, WP200, WP203, WP204, WP206, WP208, WP233, WP240, WP251, WP258, WP262

Weight of evidence 13, 33, 79, 245, 399, 423, 426, 455, 470, 503, 528, 589, MP025, MP065, MP244, MP252, RP084, TP112, TP114, TP125, WP192

Wetlands 54, 117, 281, 372, 373, 396, 603, 658, 675, 694, MP150, MP265, RP013, RP014, RP106, TP069, TP071, TP079, TP099, TP136, TP140, WP143, WP173, WP237, WP255

A Celebration of Whole Ecosystem Experiments TP135, TP136, TP137, TP138, TP139, TP140
A Dialog and Debate on Science, Sustainability and the Science of Sustainability 336, 337, 338, 339, 340, 341
Addressing Beneficial Use Impairments at Great Lakes Areas of Concern: Scientific Approaches that Lead to Restoration MP199, MP200, MP201, MP202
Advancements in Green Infrastructure Systems Through Life Cycle Assessments 677, 678, 679, 680, 681, 682, 683, 684
Advances in Passive Sampling Methods: Research to Application 49, 50, 51, 52, 53, 54, 55, 56, MP213, MP214, MP215, MP216, MP217, MP218, MP219, MP220, MP221, MP222, MP223, MP224, MP225, MP226, MP227, MP228, MP229, MP230, MP231, MP232, MP233, MP234, MP235, MP236
Advances in Sediment Quality Assessment for Regulation and Management 9, 10, 11, 12, 13, 14, 15, 16 MP237, MP238, MP239, MP240, MP241, MP242, MP243, MP244, MP245, MP246
Advances in the Toxicological Assessment of PAHs 153, 154, 155, 156, 157, 158, 159, 160, MP179, MP180, MP181, MP182, MP183, MP184, MP185, MP186, MP187, MP188, MP189, MP190
Advancing -omics into Regulatory Frameworks: Case Studies and Perspectives 33, 34, 35, 36, 37, 38, 39, 40
Advancing Fate and Effects Modeling and Their Integration to Increase the Relevance and Robustness of Risk Assessments 248, 249, 250, 251, 252, 253, 254, 255 TP143, TP144, TP145, TP146, TP147, TP148, TP149, TP150
Advancing the -omics into Regulatory Frameworks: Case Studies and Perspectives MP027, MP028, MP029, MP030, MP031, MP032
Advancing the Adverse Outcome Pathway Concept for Mitochondrial Dysfunction 374, 375, 376, 377, 378, 379, 380, 381, WP165, WP166, WP167, WP168, WP169, WP170
Adverse Effects of Chemicals on the Microbiome 605, 606, 607, 608, 609, 610, 611, 612, RP119, RP120, RP121
Alternative Animal Ecotoxicity Testing: New and Novel Approaches for Predicting Environmental Hazards and Risk Assessment 470, 471, 472, 473, 474, 475, 476, 477 WP111, WP112, WP113, WP114, WP115, WP116, WP117, WP118, WP119, WP120, WP121, WP122, WP123, WP124
Approaches and Challenges in Sediment Toxicity Testing for Environmental Risk Assessment 97, 98, 99, 100, 101, 102, 103, 104 MP164, MP165, MP166, MP167, MP168
Aquatic Toxicology, Ecology and Stress Response - Part 1 TP212, TP213, TP214, TP215, TP216, TP217, TP218, TP219, TP220, TP221, TP222, TP223, TP224, TP225, TP226, TP227, TP228, TP229, TP230, TP231, TP232, TP233, TP234, TP235, TP236, TP237, TP238, TP239, TP240, TP241, TP242, TP243, TP244, TP245, TP246, TP247, TP248, TP249, TP250, TP251, TP252, TP253, TP254, TP255, TP256, TP257, TP258, TP259, TP260, TP261, TP262, TP263, TP264, TP265
Aquatic Toxicology, Ecology and Stress Response - Part 2 RP124, RP125, RP126, RP127, RP128, RP129, RP130, RP131, RP132, RP133, RP134, RP135, RP136, RP137, RP138, RP139, RP140, RP141, RP142, RP143, RP144, RP145, RP146, RP147, RP148, RP149, RP150, RP151, RP152, RP153, RP154, RP155, RP156, RP157, RP158, RP159, RP160, RP161, RP162, RP163, RP164, RP165, RP166, RP167, RP168, RP169, RP170
Assessing Contaminant Effects in Ecosystems with Multiple Stressors with a Focus on the California Bay-Delta 685, 686, 687, 688, 689, 690, 691, 692, RP034, RP035, RP036
Assessing Contaminant Effects on Early Life Stages of Marine Organisms 438, 439, 440, 441, 442, 443, 444, 445, WP134, WP135, WP136, WP137, WP138, WP139
Assessing the Risk of Complex Mixtures: Advances and Challenges PC001, PC002, PC003, PC004, PC005, PC006, PC007
Assessment and Monitoring of Risks to Aquatic Environments from Short-Term (Episodic) Contaminant Exposures 637, 638, 639, 640, 641, 642, 643, 644, RP007, RP008
Bayesian Network Applications for Environmental Risk Assessment and Management 81, 82, 83, 84, 85, 86, 87, 88 MP024, MP025, MP026
Bioavailability-Based Aquatic Toxicity Models for Metals 41, 42, 43, 44, 45, 46, 47, 48
Birds Under Stress: Impacts of Chemical Exposure and Environmental Changes TP001, TP002, TP003, TP004, TP005, TP006, TP007, TP008, TP009, TP010, TP011, TP012, TP013
Birds Under Stress: Impacts of Chemical Exposure and Environmental Changes - Part 1 193, 194, 195, 196, 197, 198, 199, 200
Birds Under Stress: Impacts of Chemical Exposure and Environmental Changes - Part 2 280, 281, 282, 283, 284, 285, 286, 287
Bivalves as Indicators of Exposure and Ecosystem Health 541, 542, 543, 544, 545, 546, 547, 548 RP088, RP089, RP090, RP091, RP092, RP093, RP094, RP095, RP096, RP097, RP098, RP099, RP100
Bridging the Divide Between Research Scientists and Decision-Makers in Environmental Fate and Exposure Modeling MP066, MP067, MP068, MP069, MP070, MP071, MP072, MP073, MP074, MP075
Bridging the Gap Between Toxicity Method Challenges and Regulatory Compliance for Effluent and Ambient Toxicity Programs 581, 582, 583, 584, 585, 586, 587, 588, RP081, RP082, RP083, RP084, RP085, RP086, RP087
California Oil Spills: Impacts on Habitat and Wildlife 621, 622, 623, 624, 625, 626, 627, 628, RP051, RP052, RP053
Canadian Oil Sands: Advancing Science in Chemical and Toxicological Characterization, Reclamation and Monitoring 358, 359, 360, 361, 362, 363, 364, 365, WP143, WP144, WP145, WP146, WP147, WP148, WP149, WP150, WP151, WP152, WP153, WP154, WP155, WP156, WP157, WP158, WP159, WP160
Chemical Mixtures in Urban Systems - Screening and Prioritization of Emerging Contaminants 328, 329, 330, 331, 332, 333, 334, 335 TP094, TP095, TP096, TP097, TP098, TP099, TP100
Chemical Prioritization Using 21st Century Science: Considerations for New Approach Methodologies 589, 590, 591, 592, 593, 594, 595, 596, RP054, RP055
Chemical, Biological and Instrumental Methods for Detecting Harmful Algae Blooms and Their Natural Toxins 17, 18, 19, 20, 21, 22, 23, 24 MP001, MP002, MP003, MP004, MP006, MP007
Chemistry and Exposure Assessment - Posters MP102, MP103, MP104, MP105, MP106, MP107, MP108, MP109, MP110, MP111, MP112, MP113, MP114, MP115, MP116, MP117, MP118, MP119, MP120, MP121, MP122, MP123, MP124, MP125, MP126, MP127, MP128, MP129, MP130, MP131, MP132, MP133, MP134, MP135, MP136, MP137, MP138, MP139, MP140, MP141, MP142, MP143, MP144, MP145, MP146, MP147, MP148, MP149, MP150, MP151, MP152, MP153, MP154, MP155, MP156, MP157, MP158, MP159, MP160, MP161, MP162, MP163
Coupling Models with Monitoring Data and Future Perspectives for Exposure Assessment 225, 226, 227, 228, 229, 230, 231, 232, TP076, TP077
Cradle to Grave Impacts of Nanotechnology 177, 178, 179, 180, 181, 182, 183, 184 TP018, TP019, TP020, TP021, TP022, TP023, TP024, TP025, TP026, TP027
Current-Use Pesticides: Exposure and Effects on Non-Target Organisms and Ecosystems RP014, RP015, RP016, RP017, RP018, RP019, RP020, RP021, RP022, RP023, RP024, RP025, RP026, RP027, RP028, RP029, RP030, RP031, RP032, RP033
Current-Use Pesticides: Exposure and Effects on Non-Target Organisms and Ecosystems - Part 1 597, 598, 599, 600, 601, 602, 603, 604
Current-Use Pesticides: Exposure and Effects on Non-Target Organisms and Ecosystems - Part 2 693, 694, 695, 696, 697, 698, 699, 700
Dealing with Bias in Environmental Research: Case Studies and Practical Strategies 422, 423, 424, 425, 426, 427, 428, 429
Deep Learning for Predictive Toxicology MP060, MP061, MP062, MP063, MP064, MP065
Developments in Water Quality Monitoring and Analytical Methods in Support of Water Reuse WP193, WP194, WP195, WP196, WP197, WP198, WP199
Developments in Water Quality Monitoring and Analytical Methods in Support of Water Reuse - Part 1 406, 407, 408, 409, 410, 411, 412, 413
Developments in Water Quality Monitoring and Analytical Methods in Support of Water Reuse - Part 2 494, 495, 496, 497, 498, 499, 500
Ecological, Human Health, Economic and Social Impacts of Wildland Fires PC012, PC013, PC014, PC015, PC016
Ecotoxicological Impact of Multiple Stressors in Aquatic Ecosystems 25, 26, 27, 28, 29, 30, 31, 32 MP040, MP041, MP042, MP043, MP044, MP045, MP046, MP047, MP048, MP049, MP050, MP051, MP052, MP053, MP054, MP055, MP056, MP057, MP058, MP059
Ecotoxicology of Amphibians and Reptiles 366, 367, 368, 369, 370, 371, 372, 373, WP171, WP172, WP173, WP174, WP175, WP176, WP177, WP178, WP179, WP180, WP181
Effective Science Communication: Case Studies and Lessons Learned 509, 510, 511, 512, 513, 514, 515, 516, WP236, WP237
Effects of Stormwater Treatment on Receiving Water Quality WP200, WP201, WP202, WP203, WP204, WP205, WP206
Emerging Flame Retardants: State-of-the-Art Knowledge and Addressing Research Gaps 350, 351, 352, 353, 354, 355, 356, 357, WP083, WP084, WP085, WP086, WP087, WP088, WP089, WP090, WP091, WP092, WP093, WP094, WP095, WP096, WP097, WP098, WP099, WP100, WP101, WP102, WP103, WP104, WP105
Endocrine Disruption in Invertebrates: Historical Perspectives, New Developments and Key Research Needs PC008, PC009, PC010, PC011
Engineering, Remediation and Restoration WP246, WP247, WP248, WP249, WP250, WP251, WP252, WP253, WP254, WP255, WP256, WP257, WP258, WP259, WP260, WP261, WP262, WP263, WP264
Environment Exposure to Microplastics and Affiliated Toxic Chemicals 430, 431, 432, 433, 434, 435, 436, 437, WP056, WP057, WP058, WP059, WP060, WP061, WP062, WP063, WP064, WP065, WP066, WP067, WP068, WP069, WP070, WP071
Environmental Assessments for Human and Veterinary Pharmaceuticals - Evolving Regulations 613, 614, 615, 616, 617, 618, 619, 620, RP049, RP050
Environmental Mercury Exposure: Mechanisms Associated with Its Immediate and Generational Effects 565, 566, 567, 568, 569, 570, 571, 572, RP037, RP038, RP039, RP040, RP041, RP042
Environmental Pollution in Developing Economies, Policies and Population Dynamics WP012, WP013, WP014, WP015, WP016, WP017, WP018, WP019, WP020, WP021, WP022, WP023, WP024, WP025
Environmental Risk Assessment TP171, TP172, TP173, TP174, TP175, TP176, TP177, TP178, TP179, TP180, TP181, TP182, TP183, TP184, TP185, TP186, TP187, TP188, TP189, TP190, TP191, TP192, TP193, TP194, TP195, TP196, TP197, TP198, TP199, TP200, TP201,

TP202, TP203, TP204, TP205, TP206, TP207, TP208, TP209, TP210, TP211
Environmental Risk Assessment of UV Filters in Freshwater and Marine Environments 629, 630, 631, 632, 633, 634, 635, 636
Environmental Stewardship and Economic Development: How We Can Accomplish Both TP068, TP069, TP070, TP071, TP072
Environmental Stewardship in a Changing Climate - An Integration of Engineering and Environmental Science MP033, MP034, MP035
Epigenetics and Environmental Exposures: Mechanisms and Effects from Invertebrates to Fishes 121, 122, 123, 124, 125, 126, 127, 128, MP010, MP011, MP012, MP013, MP014, MP015, MP016, MP017, MP018, MP019, MP020
Evolutionary Ecotoxicology Then and Now: Decades of Progress in the Science of Evolution to Pollutants 462, 463, 464, 465, 466, 467, 468, 469 WP161, WP162, WP163, WP164
Existing, Emerging and New Chemical Contaminants in Changing Polar Environments 240, 241, 242, 243, 244, 245, 246, 247 TP028, TP029, TP030, TP031, TP032, TP033, TP034, TP035, TP036, TP037, TP038
Exposure Assessment and Modeling for Ecological Risk Assessment of Veterinary Pharmaceuticals and Pesticides 145, 146, 147, 148, 149, 150, 151, 152, MP021, MP022, MP023
Exposure to Crude Oils: Linking Laboratory Endpoints to Field Observations 446, 447, 448, 449, 450, 451, 452, 453, WP218, WP219, WP220, WP221, WP222, WP223, WP224, WP225, WP226
Fate and Effects of Chemicals from Diffuse Sources and Stormwater WP106, WP107, WP108, WP109, WP110
Fate and Effects of Chemicals from Diffuse Sources and Stormwater - Part 1 414, 415, 416, 417, 418, 419, 420, 421
Fate and Effects of Chemicals from Diffuse Sources and Stormwater - Part 2 501, 502, 503, 504, 505, 506, 507, 508
Fate and Effects of Metals - Mechanisms of Bioavailability and Toxicity 129, 130, 131, 132, 133, 134, 135, 136, MP081, MP082, MP083, MP084, MP085, MP086, MP087, MP088, MP089, MP090, MP091, MP092, MP093, MP094, MP095, MP096, MP097, MP098
Fate and Effects of Metals - Regulatory and Risk Assessment Perspective 390, 391, 392, 393, 394, 395, 396, 397, WP026, WP027, WP028, WP029, WP030, WP031, WP032, WP033
Fate and Effects of Metals: Biogeochemical Perspective 217, 218, 219, 220, 221, 222, 223, 224 TP073, TP074, TP075
Fate of Organic Contaminants in Aquatic Invertebrates and Their Environments - Measurement, Modeling and Risk Management 1, 2, 3, 4, 5, 6, 7, 8, MP195, MP196, MP197, MP198
Fate, Toxicology, or Risk Assessment of Materials of Interest to the Military WP001, WP002, WP003, WP004, WP005
High-Throughput Screening and Ecological Risk Assessment WP185, WP186, WP187, WP188, WP189, WP190, WP191, WP192
Human Exposure to Emerging Environmental Contaminants 342, 343, 344, 345, 346, 347, 348, 349 TP042, TP043, TP044, TP045, TP046, TP047, TP048, TP049, TP050, TP051, TP052, TP053, TP054, TP055, TP056, TP057, TP058, TP059, TP060, TP061, TP062, TP063, TP064, TP065, TP066, TP067
Human Health and Ecological Risk Assessment of Poly and Perfluoroalkyl Substances 256, 257, 258, 259, 260, 261, 262, 263, TP151, TP152, TP153, TP154, TP155, TP156, TP157, TP158, TP159, TP160, TP161, TP162, TP163, TP164, TP165, TP166
Identifying Unknown Causes of Toxicity: Proven and Innovative Methods TP109, TP110, TP111, TP112, TP113, TP114, TP115, TP116, TP117, TP118
Immunoanalytical Technologies: Development and Applications for Environmental Monitoring 320, 321, 322, 323, 324, 325, 326, 327 TP014, TP015, TP016, TP017
Immunotoxicology: Identifying Adverse Effects, Developing New Approaches and Confronting Existing Challenges 65, 66, 67, 68, 69, 70, 71, 72, MP037, MP038, MP039
Impacts of Unconventional Gas Operations on Surface Waters, Soils and Groundwater - An International Perspective 557, 558, 559, 560, 561, 562, 563, 564 RP101, RP102, RP103, RP104
Improving Approaches to Assess Risks to Threatened and Endangered Species from Chemical Exposure 454, 455, 456, 457, 458, 459, 460, 461, RP009, RP010, RP011, RP012, RP013, PC017, PC018, PC019, PC020
Improving Chemical Assessments Using Toxicokinetic Data WP072, WP073, WP074, WP075, WP076, WP077, WP078, WP079, WP080, WP081, WP082
In Situ Treatment of Contaminated Sediments - What Are the Remaining Barriers? 486, 487, 488, 489, 490, 491, 492, 493, WP053, WP054, WP055
Incorporating Effect-Based Molecular Assays in Environmental Monitoring and Risk Assessment 296, 297, 298, 299, 300, 301, 302, 303, TP126, TP127, TP128, TP129, TP130, TP131, TP132, TP133, TP134
Incorporation of Sustainability into Undergraduate Curricula in Science and Engineering WP046, WP047, WP048
Indoor Human Exposure to Particulate Matter and Persistent Toxic Chemicals: Emission Patterns, Fate and Health Risk MP099, MP100, MP101
Integrating Big Data Into the Bigger Picture 312, 313, 314, 315, 316, 317, 318, 319, TP089, TP090
Integrating Cooperative Federalism into Environmental Research and Assessments WP049, WP050, WP051, WP052
Interpreting Biological Effects of Metals and Their Mixtures in the Aquatic and Terrestrial Environments 304, 305, 306, 307, 308, 309, 310, 311 TP119, TP120, TP121, TP122, TP123
Linking Mechanism of Action to Physiological and Ecological Effects in Aquatic Species 209, 210, 211, 212, 213, 214, 215, 216 TP101, TP102, TP103, TP104, TP105, TP107, TP108
Mechanistic Ecotoxicology: Bridging the Gap from Investigative to Regulatory Ecotoxicology 525, 526, 527, 528, 529, 530, 531, 532
Micro- and Nanoplastic Methods for Environment Media 517, 518, 519, 520, 521, 522, 523, 524, WP034, WP035, WP036, WP037, WP038, WP039, WP040, WP041, WP042, WP043, WP044, WP045
Micro-organisms and Biopesticides in Crop Production: Use and Environmental Safety Considerations 185, 186, 187, 188, 189, 190, 191, 192, TP124, TP125
Modeling and Data Analysis Tools to Predict the Fate and Transport of Pesticides in the Environment 382, 383, 384, 385, 386, 387, 388, 389, WP227, WP228, WP229, WP230, WP231, WP232, WP233, WP234, WP235
Modeling Oil and Chemical Transport in the Water Column After Spills 533, 534, 535, 536, 537, 538, 539, 540, RP112, RP113, RP114, RP115, RP116, RP117, RP118
Monitoring, Remediation and Ecotoxicological Assessment of Emerging Contaminants in Soil and Water 137, 138, 139, 140, 141, 142, 143, 144, MP008, MP009
Non-Conventional Exposure Routes and Transport Media of Consumer Product Chemicals to Improve Environmental Policy 645, 646, 647, 648, 649, 650, 651, 652, RP122, RP123
Non-Targeted Analysis: Comparing ENTACT Results and Assessing Informatics Approaches 233, 234, 235, 236, 237, 238, 239 TP167, TP168, TP169, TP170
Novel Approaches for Understanding Diversity in Species Sensitivity to Chemicals 549, 550, 551, 552, 553, 554, 555, 556, RP076, RP077, RP078, RP079, RP080
One Health in Action - Tangible Applications for Problem Solving and Coalition Building 169, 170, 171, 172, 173, 174, 175, 176, MP192, MP193, MP194
Pathological Endpoints as Predictive Tools for Relative Ecological Risks of Species TP141, TP142
Per- and Poly-fluoroalkyl Substances: Recent Advances and Future Directions MP203, MP204, MP205, MP206, MP207, MP208, MP209, MP210, MP211, MP212
Per- and Poly-fluoroalkyl Substances: Recent Advances and Future Directions - Part 1 73, 74, 75, 76, 77, 78, 79, 80
Per- and Poly-fluoroalkyl Substances: Recent Advances and Future Directions - Part 2 89, 90, 91, 92, 93, 94, 95, 96
Persistence and Biodegradability Assessment 264, 265, 266, 267, 268, 269, 270, 271 TP084, TP085, TP086, TP087, TP088
Pesticide Runoff Pollution: Challenges and Opportunities in Prediction, Prevention and Management 272, 273, 274, 275, 276, 277, 278, 279, TP079, TP080, TP081, TP082, TP083
Pilot Studies - In Search of Innovative Remedial and Restoration Design MP076, MP077, MP078, MP079, MP080
Plants in Environmental Risk Assessment: Assessing and Predicting the Effects of Chemicals on Plant Communities 573, 574, 575, 576, 577, 578, 579, 580, RP043, RP044, RP045, RP046, RP047, RP048
Policy, Management and Communication WP240, WP241, WP242, WP243, WP244, WP245
Poster Only - Late Submissions RP171, RP172, RP173, RP174, RP175, RP176, RP177, RP178, RP179, RP180, RP181, RP182, RP183
Predictive and Statistical Toxicology MP247, MP248, MP249, MP250
Protecting Freshwaters from Salinization 669, 670, 671, 672, 673, 674, 675, 676 RP001, RP002, RP003, RP005, RP006
Recent Advances in Training, Online Support and Responsible Management Practices for LCA Databases WP127, WP128, WP129, WP130, WP131, WP132, WP133
Remediation and Restoration: Assessing and Measuring Effectiveness for Contaminated Sediments 398, 399, 400, 401, 402, 403, 404, 405, WP182, WP183, WP184
Responsible Chemical Use and Innovative Alternatives for Protecting Infrastructure, Property and Natural Resources 288, 289, 290, 291, 292, 293, 294, 295
Selenium Ecotoxicology and Management Going on 40: What Do We Know and How Can We Apply It? 478, 479, 480, 481, 482, 483, 484, 485 WP207, WP208, WP209, WP210, WP211, WP212, WP213, WP214, WP215, WP216, WP217
Soil Contaminants: Fate, Bioavailability, Environmental Toxicology in Ecological and Human Health Risk Assessment 661, 662, 663, 664, 665, 666, 667, 668 RP056, RP057, RP058, RP059, RP060, RP061, RP062, RP063, RP064, RP065, RP066, RP067, RP068, RP069, RP070, RP071, RP072, RP073, RP074, RP075
Sustainability and Ecosystem Services: From Science to Societal Choices WP125, WP126
Systems Approaches WP238, WP239
Tackling Urban Background: Approaches, Case Studies and Policy Implications WP140, WP141, WP142
Teaching Environmental Chemistry: Where Are We and Where Are We Going? 57, 58, 59, 60, 61, 62, 63, 64
Terrestrial Toxicology, Ecology and Stress Response MP251, MP252, MP253, MP254, MP255, MP256, MP257, MP258, MP259, MP260, MP261, MP262, MP263, MP264, MP265, MP266, MP267

The Need for Data and Data Management Tools to Address ESA-listed Species Protection and Agricultural Production Goals 113, 114, 115, 116, 117, 118, 119, 120
The Use of Historical Control Data in Ecotoxicological Study Assessments TP091, TP092, TP093
Translating Environmental Science into Improved Outcomes and Policy 201, 202, 203, 204, 205, 206, 207, 208, TP039, TP040, TP041
Using Non-Conventional Animal Models in Ecotoxicological and Genotoxicological Studies for Risk Assessment Applications WP006, WP007
Water and Land Management to Reduce Methylmercury Bioaccumulation 653, 654, 655, 656, 657, 658, 659, 660, RP105, RP106, RP107, RP108, RP109, RP110, RP111
Water: Bringing Science and Engineering Together to Address Impacts of Climate Change on Water Supply and Water Quality 161, 162, 163, 164, 165, 166, 167, 168
What Matters: Global Perspectives in Advancing Science into Environmental Risk Assessment WP008, WP009, WP010, WP011
Wildlife Ecotoxicology Supporting Management Decision Making 105, 106, 107, 108, 109, 110, 111, 112, MP169, MP170, MP171, MP172, MP173, MP174, MP175, MP176, MP177, MP178
Wildlife Forensics Toxicology TP078
